A measured volume of soil extract containing 5—10 mgrms. P_2O_5 is evaporated to dryness and the residue ignited at a dull red heat for 15 mins., or if much silica is present for two hours at 120°—160° C. It is then digested for half an hour on a sand bath with 50 c.c. of 10% sulphuric acid, the extract diluted, and filtered, and the residue washed with hot water. The solution is treated with 25 c.c. of concentrated ammonium nitrate (500 grms. per litre), warmed to 55° C., 25 c.c. of ammonium molybdate (150 grms. in 1 litre of water poured into 1 litre of nitric acid of sp. gr. 1·2) at the same temperature added and the mixture allowed to cool. After two hours the precipitate is washed several times by decantation with 2% sodium nitrate solution, filtered off, dissolved in excess of standard (*N*/10) alkali and the excess titrated back with standard acid. The best factor is 1 c.c. of *N*/10 alkali = 0·0003004 grm. P_2O_5. It is important to remove all silica and to avoid too high a temperature for precipitation. The method is quicker and more accurate than the lead molybdate method of Brearley and Ibbotson ("*Anal. of Steel Works Materials*").—W. H. P.

Sulphites, thiosulphates and sulphur present in soil; Influence of —— on the growth of the plant. W. Thalau. Landwirtsch. Versuchsst., 1913, **82**, 161—209. Biedermann's Zentr., 1914, **43**, 228—231.

Ammonium sulphite is equal to ammonium sulphate as a manure on loamy soils. On sandy soils it is not quite so good, while on peaty soils it is considerably less effective. In water cultures it is harmful even in very small quantities: at concentrations higher than 0·4% it retards germination, and at 1% it prevents germination entirely, while 1% ammonium sulphate has no harmful action at all. Ammonium sulphite is readily oxidised to sulphate when exposed to air, the oxidation being more rapid in solution and still more rapid when the salt is mixed with soil. Calcium sulphite is harmless in loamy and sandy soils. On peaty soils it has a slight retarding effect; and n water cultures increasing quantities of calcium sulphite roduce a progressive decrease in the yield. Sodium hiosulphate appears to have no harmful action on plant growth. Flowers of sulphur is somewhat variable in its effects, but it does not usually increase growth or yield. —W. H. P.

XVII.—SUGARS; STARCHES; GUMS.

Cane sugar factory; Studies in the ——. [*Analyses of sugar canes, cane juices, the ash of cane juice and cane syrup, incrustations of juice-heaters and defecators.*] C. Fribourg. Bull. Assoc. Chim. Sucr., 1914, **31**, 778—802.

Louzier cane.—An average sample of this variety, which is almost exclusively worked in Brazil, contained: fibre, 10·50; sucrose, 15·42; non-sugar, 3·44; and water, 70·64%. *Juice of Louzier cane.*—Juice obtained by dry crushing in a laboratory 3-roller mill, gave the following figures in grms. per 100 c.c for (a) the apparent and (b) the true analysis: Sucrose, (a) 20·04, (b) 20·31; reducing sugars, (a) 1·16, (b) 1·31; ash, (a) 0·35, (b) 0·34; organic matter, (a) 1·38, (b) 0·64; Brix degree, (a) 22·93, (b) 22·60; purity, (a) 87·40, (b) 89·80; saline coefficient, (a) 57·20, (b) 59·70; glucose ratio, (a) 5·80, (b) 6·40; ratio of ash to organic matter, (a) 3·94, (b) 1·88. *Ash of the Louzier cane.*—SiO_2, 25·96; Al_2O_3, 0·02; Fe_2O_3, 1·02; Mn_2O_3 0·68; CaO, 7·64; MgO, 9·19; K_2O, 36·17; Na_2O, 1·39; CO_2, 6·91; SO_3, 3·21; P_2O_5, 7·18; Cl, 0·81. *Composition of Louzier and Ribbon canes according to their height.*—Results confirming in a general way those of other workers were obtained, these indicating that the density of the juice is lowest near the root, at its maximum in the middle of the stalk, and gradually diminishes towards the top; the purity of the juice is highest near the root, and gradually diminishes towards the top; the sucrose content is practically the same for three-quarters of the height, but is distinctly lower in the top quarter; the reducing sugars, ash, and acids are lowest near the root, and highest at the top; while the fibre content is highest at the root end. *Composition of the ash of mill juice and clarified syrup.*—The raw juice was sulphited to an acidity of 0·75 grm. per litre, limed to neutrality in the cold, heated to 60° C. in reheaters, and allowed to settle in the usual way, the clear juice being separated from the top scums and the bottom muddy juice. Analysis of the ash of (a) the raw unsulphited mill juice, and (b) the clarified syrup after evaporation, gave the following values, expressed in parts per 1000 of sucrose: SiO_2, (a) 1·99, (b) 0·88; Al_2O_3, (a) 0·05, (b) 0·01; Fe_2O_3, (a) 0·43, (b) 0·14; Mn_2O_3, (a) 0·12, (b) 0·03; CaO, (a) 1·12, (b) 5·47; MgO, (a) 1·37, (b) 1·89; K_2O, (a) 15·36, (b) 16·02; Na_2O, (a) 0·68, (b) 0·38; CO_2, (a) 4·86, (b) 8·93; SO_3, (a) 0·97, (b) 2·10; P_2O_5, (a) 2·07, (b) 0·30; Cl, (a) 0·48, (b) 0·60. The total amount of ash per 1000 of sugar had increased, owing to the introduction of sulphites and sulphates in sulphitation, and of lime and magnesia in defecation; while the silica, oxides of iron and alumina, and phosphoric acid had diminished, having passed into the scums. *Incrustation from limed juice-heater.*—Water (at 100° C.), 1·86; organic matter (including bagasse) and combined water, 26·65; sand, 0·18;

silica, 0·12 ; calcium sulphate, 6·56 ; calcium phosphate, 51·13, magnesia, 0·36, ferric oxide, 1·46 ; lime combined with organic acids, 4·90 ; alkalis, carbonic acid, and undetermined matter, 6·78%. *Incrustation from raw juice defecator.*—Water, 8·54 ; organic matter (including a large proportion of bagasse), 33·55 ; sand and silica, 0·45 ; calcium sulphate, 2·82 ; calcium phosphate, 48·38 ; and undetermined substances, 6·26%. *Incrustations from triple effect evaporators.*—The deposit from the first body has a similar composition to those found in the limed juice re-heater and the defecators ; calcium sulphate is present mostly in the first and least in the third body ; on the contrary, calcium oxalate, which is not met with in the deposits of re-heaters and defecators, nor in the first body of the triple effect, appears in considerable amount in the second, and to an even greater extent in the third body ; combined silica is principally deposited in the last body.—J. P. O.

Clarification of Louisiana cane juices ; Sulphitation and carbonatation processes for the ——. W. E. Cross. Agric. Expt. Station, Louisiana State Univ., Bull. 144, 1914, 39 pages.

Sulphitation.—The Java method of liming before sulphitation is not suited to Louisiana juices, owing to risk of the decomposition by lime of the reducing sugars, which are high in Louisiana juices. For white sugar manufacture, the maximum limit to which the raw juice may be sulphited in most factories in the State is such that 8 c.c. of $N/10$ sodium hydroxide solution are required to render 10 c.c. of the juice neutral to phenolphthalein ; under these conditions a hard filter-press cake and light mobile juices are obtained. After the sulphitation of the raw juice, a precipitate containing : moisture, 4·07 ; fat and wax, 32·57 ; proteins, 23·63 ; ash, 9·48 ; crude fibre, 8·05 ; and gums, etc., 22·20% separated. A sensible increase in the purity of the raw juice was effected by the removal of this precipitate, and although in the factory its filtration was impracticable, promising results were obtained by centrifugal separation. In "liming back" Louisiana juices, which on the average contain 10% of sucrose and 1·5% of reducing sugars, the most suitable point was found to be neutrality to litmus, corresponding to 0·8—1·0 c.c. of $N/10$ sodium hydroxide solution per 10 c.c. of juice, using phenolphthalein as indicator; at this stage the muddy juice settled well, and there was no danger of it becoming alkaline on boiling. Before evaporation in the effect, this acidity could be increased with advantage regarding the colour of the syrup subsequently obtained ; in factory trials no measurable amount of inversion occurred with an acidity corresponding to 1·0 c.c. of $N/10$ sodium hydroxide solution per 10 c.c. of juice, but there was a distinct risk if it was increased to 1·5 c.c. It is of much importance in making white sugar that the clarified juice be free from all suspended matter when taken into the effect, and the use of mechanical filters in addition to settling is advocated.

Carbonatation.—In Louisiana the carbonatation process, successfully used in Java, has not made much progress, owing to the high glucose content of the juices, but the results of the past three grinding seasons have shown that it can be applied, provided the juices be not heated above 40°—50° C., when the products of the decomposition of the reducing sugars are neither dark-coloured nor melassigenic. Either single or double carbonatation may be applied, the alkalinity of the first saturation in double carbonatation being stopped at a point corresponding to 1·2—1·8 c.c. of $N/10$ acid per 10 c.c. of juice, and the temperature of filtration never rising higher than 50° C. Harloff's acid thin juice process (this J., 1913, 1035) may be applied to Louisiana juices with success, though the need of filtering at 70° C., necessitates the use of a large amount of lime in single carbonatation, viz., 1·2—2·5%.

Syrup treatment.—Sulphitation syrups did not filter readily, and it was best to heat them to 70° C., add 1—2 parts of sodium phosphate per 100,000 parts, and allow to settle ; treatment with sulphurous or phosphoric acids was also often helpful. Carbonatation syrups were usually easy to filter, and with these also improvement was effected by addition of sulphurous or phosphoric acids, the amount depending upon the original acidity of the clarified juice.—J. P. O.

[*Sugar.*] *Diffusion ; Temperature at which* —— *should be operated.* A. Herzfeld and L. Kuntze. Deut. Zuckerind., 1914, 39, 289—291.

According to Herzfeld, a temperature above 40°—50° C. is preferable in operating the ordinary process of diffusion, and when the Pfeiffer-Bergreen or other method of returning the residuary waters to the battery (this J., 1906, 328 ; 1907, 704 ; and 1913, 954) is applied, about 70° C. should be maintained throughout, in order to inhibit the action of micro-organisms, and prevent the formation of gas. Such methods of "hot" diffusion produce a pulp of better keeping qualities, either in the open air or in the silo than "cold" diffusion. Kuntze obtained satisfactory results when filtering the residuary diffusion and press waters, and using them in place of fresh water throughout the campaign, by working at the following temperatures in a 9-cell battery : in the first, freshly charged, 38°—40° ; in the second, 60° ; in the third to the seventh, 82° ; in the eighth, 75° ; and in the last, 40°—50° C. The essential conditions for successful working with residuary waters are great rapidity and the avoidance of any stoppage. Provided the pulp is siloed immediately after being discharged, and well covered with earth, it keeps well.—J. P. O.

Intermediate [*beet*] *juice ; Analysis of a precipitate from the sulphitation of* ——. A. Kiroff. Deut. Zuckerind., 1914, 39, 419.

On sulphiting the intermediate juice in a Russian beet factory, difficulty was subsequently experienced in passing it through the cloths of a mechanical filter owing to the slimy nature of the precipitate, analysis of which gave the following figures : water, 4·09 ; insoluble in hydrochloric acid, 4·59 ; sugar from the intermediate juice, 19·30 ; non-sugar, 1·57 ; calcium sulphite, 44·94 ; calcium sulphate, 1·31 ; calcium salts of organic acids, 19·00 ; calcium otherwise combined, iron and alumina, 2·12 ; fat, 1·38%.—J. P. O.

Nipa palm ; The —— *as a commercial source of sugar* D. S. Pratt, R. R. Williams and H. D. Gibbs. Philippine J. Sci., 1913, 8, A, 377—398.

The nipa palm, *Nipa fruticans* Wurmb., is abundant in swamps in the Philippine Islands and other parts of the tropics. The juice obtained from the flower stalk is used on a large scale as a commercial source of alcohol, and the authors' experiments have led to the conclusion that the nipa palm should furnish a cheap supply of sugar. The nipa palm produces about 40 litres of sap per tree in an average season, and at a conservative estimate a yield of about 30,000 litres of sap pér hectare per year should be obtained. The sap is available in sufficient quantity for the supply of sugar mills for about six months in the year; contains on an average about 15% of sucrose and has an apparent purity of not less than 85 ; traces of invert sugar are present and about 0·5% of sodium chloride, but waxes, acids, and pectins are absent. The chief difficulty is the presence in the sap of enzymes of the invertase and peroxidase types which cause inversion and decomposition of the sugar with great rapidity ; by placing a small amount of lime cream and sulphite in the collecting vessel—which should be fitted with a funnel to cause the sap to mix thoroughly with the lime cream—the enzyme action can be inhibited and the sap will then keep without decomposition for several hours. The sulphite also renders further bleaching at the sugar mill unnecessary It is estimated that sap can be delivered to the sugar mills at about 1·5 dollars (U.S.A. currency) per 1000 litres from which 115 kilos. of commercial white sugar polarising 99°—99·5° can be obtained. About 9000 litres of sap would be required to produce 1 metric ton of 96° sugar a 10-ton mill would require therefore 90,000 litres of sap daily, or the produce of about 450 hectares of nipa swamp

—R. G. P.

Lactose and dextrose, Determination of —— by the copper-iodide method. S. W. Cole. Biochem. J., 1914, **8**, 134—142.

A rigorously standardised modification of Schoorl's method (this J., 1899, 791), similar to one described by Peters (J. Amer. Chem. Soc., 1912, **34**, 928), in which the cuprous oxide is filtered off before the unreduced copper is titrated. A table is given for lactose, corresponding to that for dextrose given in Peters' paper.—J. H. L.

Lævulose; Simple qualitative and quantitative tests for —— in presence of other sugars. E. Pinoff and K. Gude. Chem.-Zeit., 1914, **38**, 625—626.

The following qualitative test is more satisfactory than that previously described (this J., 1905, 1192):—6 grms. of finely powdered ammonium molybdate dissolved in 5 c.c. of boiling water, are cooled to 40° C. and mixed with 5 c.c. of the liquid to be tested (containing 0·03—1 grm. of sugar) which must contain no free acid. The mixture, kept at 40° C. for 15 mins., becomes blue if lævulose is present. The only other sugar which reacts in this way is dextrose, but the colour produced by 1 grm. of the latter is only equal in intensity to that produced by 0·03 grm. of lævulose.

The diphenylamine colour test may be applied quantitatively as follows:—2·5 c.c. of the liquid to be tested (containing not more than 20% of sugar) are mixed with 2·5 c.c. of 96% alcohol, 10 c.c. of a mixture of alcohol with sulphuric acid (750 c.c. of 96% alcohol and 200 c.c. of concentrated acid), and 0·1 grm. of diphenylamine, and the mixture is heated to 70° C. in 15 mins. under a reflux condenser, maintained in ebullition for 3 mins., quickly cooled, poured into a Hehner colorimeter vessel (or a measuring cylinder of 3 cm. width) and the colour observed through a spectrometer. If the original sugar solution contains lævulose, the liquid after heating is blue and shows a broad absorption band ($\lambda = 500$—550). The band is only just distinctly visible when the original solution contains 0·036% of lævulose and larger quantities are estimated by ascertaining the extent to which the final liquid must be diluted (with alcohol) to reduce the intensity of the band to correspond with this quantity of lævulose.—J. H. L.

Maltose: Action of dilute solutions of barium and other hydroxides on ——. L. Kolb. Biochem. Zeits., 1914, **63**, 1—57.

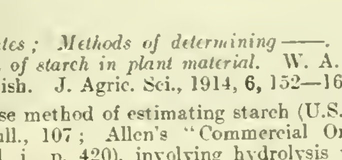
Maltose was decomposed by the hydroxides of lead, magnesium, calcium, strontium, and barium to an extent which depended on the degree of dissociation of the hydroxide; of the alkaline-earth hydroxides, barium hydroxide acted most strongly. The decomposition, as indicated by the fall in optical activity of the solution, was accelerated by rise of temperature, but was characterised at all temperatures by an initial rapid phase followed by a slow phase; the solution could be rendered quite inactive if a sufficient quantity of hydroxide was employed. In the course of decomposition, the solution always became more or less intensely brown. Barium hydroxide first converted maltose into dextrose, a rapid reaction which corresponded to the initial rapid fall in optical activity. The dextrose was slowly converted into an inactive mixture of lævulose, mannose, dextrose (cp. Lobry de Bruyn and van Eckenstein, this J., 1896, 210) and glutose (?), these changes corresponding to the slow fall in optical activity. Organic acids were also formed. —L. E.

Sucrose; Inversion of —— by acids in water-alcohol solutions. G. J. Burrows. Chem. Soc. Trans., 1914, **105**, 1260—1270.

The rate of inversion of sucrose by hydrochloric or sulphuric acid in mixtures of water and ethyl alcohol up to 75% of the latter falls to a minimum as the proportion of alcohol is increased to 45—50% and then increases again. Since the conductivity of the acid is a function of its dissociation and of the mobility of the ions (and therefore of the fluidity of the solution), the values obtained by dividing the inversion velocity constants by the conductivities of the corresponding solutions, represent the influence of the solvent on the activity of the catalyst. These values show that the catalytic activity of the hydrogen ions is greater in alcoholic than in aqueous solutions. The activity of *N*/2 hydrochloric acid relative to that of *N*/2 sulphuric acid is greater in mixtures of alcohol and water than in water alone.—L. E.

Glucoses; Partially methylated ——. III. Monomethylglucose. J. C. Irvine and T. P. Hogg. Chem. Soc. Trans., 1914, **105**, 1386—1396.

Monomethylglucose (m. pt. 160·5°—161° C.) is obtained by hydrolysis of monomethylglucosediacetone which is formed by the action of methyl iodide and silver oxide on glucosediacetone. Since monomethylglucose yields, on strong oxidation with nitric acid, not a dibasic acid but monomethylgluconolactone, and also gives the same phenylosazone as is obtained from monomethylfructose, its constitution is:—



$$CH_3\cdot O\cdot CH_2\cdot \overset{H}{\underset{OH}{C}}\cdot \overset{H}{C}\cdot \overset{OH}{\underset{H}{C}}\cdot \overset{H}{\underset{OH}{C}}—CHOH$$

The α- and β-forms of the sugar exhibited mutarotation, the initial rotatory powers being $[\alpha]_D = +107{\cdot}6$ and $+24{\cdot}4$ and the permanent rotations 68·5° and 68·3° respectively.—L. E.

Carbohydrates; Methods of determining ——. II. Determination of starch in plant material. W. A. Davis and A. J. Daish. J. Agric. Sci., 1914, **6**, 152—168.

The Sachsse method of estimating starch (U.S. Bureau of Chem., Bull., 107; Allen's "Commercial Org. Anal.," 4 Ed., Vol. i., p. 420), involving hydrolysis with dilute hydrochloric acid, is unreliable in the presence of plant material. The tissues invariably contain pentosans which yield pentoses that count as dextrose, and actual destruction of dextrose takes place during the prolonged treatment with dilute acid. O'Sullivan's method (Chem. Soc. Trans., 1884, **45**, 1; also this J., 1904, 137), involving the use of diastase, gives low results owing to the loss of dextrin which takes place on purifying the solution by the precipitation method after the conversion. The use of Taka-diastase avoids this objection as it yields only dextrose and maltose (free from dextrin) and no loss of these sugars occurs when the solution is treated with clearing agents such as lead acetate. In the preparation of the plant material it is necessary to destroy all enzymes immediately the sample is taken. This is done by dropping the leaf or other material into boiling 95% alcohol containing a little ammonia. The sugars are removed by extraction with boiling alcohol. If necessary gums, etc., are removed by extraction with water, as their optical activity would lead to an error in the subsequent starch estimation. The extracted material is usually preserved in a bottle and great care must be taken in subsequent sampling, owing to the tendency for starchy matter to accumulate at the bottom. About 10 grms. of the oven-dried extracted material are dried *in vacuo* at 100°—110° C. for 24 hours or longer, and then gelatinised with 200 c.c. of water. After cooling to 38° C., 0·1 grm. of Taka-diastase and 2 c.c. of toluene are added and the mixture left for 24 hours. It is then heated to boiling, filtered, washed, and the filtrate together with a sufficient quantity of basic lead acetate is made up to 500 c.c., and again filtered. In 100 c.c. of filtrate the slight excess of lead is precipitated by sodium carbonate, the solution made up to 110 c.c., and filtered. 50 c.c. of the filtrate are used for reduction and another portion is polarised in a 400 mm. tube. From the reduction and polarimetric data the dextrose and maltose and hence the original starch can be calculated. —W. H. P.

The Charpentier thermal ozoniser, and its application in the distillery and sugar factory. Sidersky. *See* XIXb.

Patents.

Sugar-containing juice; Process of purifying raw ——. J. Carniol, Vienna. U.S. Pat. 1,095,189, May 5, 1914.

The sliced material containing the juice is treated with powdered limestone, and the juice is heated to about 70° C., mixed with powdered limestone and sufficient lime to produce an alkalinity of 0·3% on saturation, and filtered.—J. H. L.

Sugars; Process of producing fermentable —— [from cellulosic materials]. F. E. Gallagher, Newton, and H. S. Mork, Boston, Mass., Assignors to Standard Alcohol Co., New York. U.S. Pat. 1,096,030, May 12, 1914.

As one step in the production of sugars from lignocellulose or other cellulosic material, the mass is digested under pressure with a dilute solution of sulphuric acid and a soluble metallic chloride (*e.g.*, sodium chloride).—J. H. L.

Betaine or its salts; Manufacture of —— from molasses, exhausted molasses, or other residues of the beet sugar factory. Act.-Ges. f. Anilinfabr., Treptow, Germany. Eng. Pat. 2813, Feb. 3, 1914. Under Int. Conv., May 7, 1913.

The exhausted molasses or other raw material is freed as far as possible from water by evaporation in a vacuum and the residue is mixed with concentrated hydrochloric acid under such conditions that a temperature favourable to the formation of humic substances is not reached (*e.g.*, the temperature should not exceed 50° or 60° C.). When the mass is cooled, practically the whole of the betaine separates in the form of hydrochloride mixed with alkali chlorides, which are separated by the usual methods, such as by crystallising from methyl alcohol and recrystallising from water.—T. F. B.

Sugars; Process for producing fermentable ——. F. E. Gallagher, Troy, N.Y., U.S.A. Eng. Pat. 14,937, June 28, 1913. Under Int. Conv., July 15, 1912.

See U.S. Pat. 1,056,161 of 1913; this J., 1913, 441.—T. F. B.

XVIII.—FERMENTATION INDUSTRIES.

Wort; Assimilable nitrogen in —— and its relation to the yeast and fermentation. F. Schönfeld. Woch. Brau., 1914, **31**, 197—199.

Of the soluble nitrogenous matter in beer wort, 45—65% is assimilable by yeast, but owing to the conditions of fermentation, only 15—30% is actually assimilated. In the determination of assimilable nitrogen in wort by fermentation, the wort is much diluted, treated with a considerable quantity of sugar and a very large quantity of fresh distillery yeast, and fermented at a high temperature with vigorous aeration and stirring; the assimilable nitrogen is thus removed in 5—6 hours. The results tend to be rather low since nitrogenous matter may diffuse into, and remain in the wort, but the error thus introduced is not serious. During fermentation, beer worts of high nitrogen-content lose less nitrogen, absolutely as well as relatively, than worts poor in nitrogen, since the yeast "breaks" much more readily in the former case and thus loses much of its power to assimilate nitrogen. The loss of much nitrogen, characteristic of worts poor in nitrogen, accompanies a high attenuation. The amount of assimilable nitrogen in Berlin "Weissbier" wort does not exceed 45%, but almost all of this is assimilated, and the final attenuation is attained in the primary fermentation.—L. E.

Sucrase; Thermoregeneration of ——. G. Bertrand and M. Rosenblatt. Comptes rend., 1914, **158,** 1455—1458.

The authors confirmed a recent observation of Durieux (this J., 1914, 561), that if dried yeast is macerated in water and portions of the mash are heated for 1 min. at various temperatures and subsequently filtered, the filtrates which have been heated at 90° or 100° C. exhibit greater inverting activity towards sucrose than those heated at 70° or 80° C. This "thermoregeneration," was observed with different kinds of yeast, and appears to be a consequence of autolysis, for it is the more marked the more slowly the yeast is dried prior to maceration. Thus, it was not shown by fresh baker's yeast after grinding with sand or killing by successive treatments with alcohol and ether, whereas the same kind of yeast dried slowly at 35° C. (48 hours or longer) and then macerated for 2 hours, and heated for 1 min. at the temperatures indicated, gave the following values for the relative invertase activities of the filtered juices:—not heated, 3·377; heated at 50°, 3·292; heated at 70°, 0·068; heated at 80°, 0·150; heated at 90°, 2·446; heated at 100° C., 3·430. A sample of yeast killed by acetone and dried, behaved similarly, but in a less marked degree. —J. H. L.

Yeast; Enzymes of washed zymin and dried —— (v. Lebedeff). I. Carboxylase. A. Harden. *II. Reductase.* A. Harden and R. V. Norris. Biochem. J., 1913, **7**, 214—217; 1914, **8**, 100—106.

Zymin and dried yeast (prepared by v. Lebedeff's method) after being freed from co-enzyme by washing, and thus rendered incapable of fermenting dextrose (see Euler and Backström, this J., 1912, 404), readily decompose pyruvic acid into carbon dioxide and acetaldehyde (cp. Neuberg and others, this J., 1911, 379, 1179) provided that the acidity of the solution is kept low. If therefore the decomposition of pyruvic acid actually be a stage in the alcoholic fermentation of dextrose, the soluble co-enzyme must be required for some stage precedent to the production of pyruvic acid.

The presence of a fermentable sugar favours the reduction of sodium selenite by living yeast, but has little influence on the reducing power of zymin unless the sugar is present in high concentration, when inhibition occurs (cp. Palladin, this J., 1908, 870). Sodium selenite at a concentration of 0·5% almost totally inhibits the fermentation of dextrose by zymin and dried yeast (10 grms. per 100 c.c. of 10% dextrose solution), an effect much greater than can be explained by Lvoff's hypothesis (see this J., 1913, 955, 1167). When dried yeast or zymin is washed with cold water until incapable of fermenting sugar, it loses its power of reducing methylene blue and sodium selenite. Such washed preparations reduce methylene blue in presence of many aldehydes (not, however, formaldehyde or acetaldehyde) or of bouillon, but these do not restore the power of producing alcoholic fermentation. Addition of the boiled washings to the washed preparations restores both the power of fermenting sugar and reducing methylene blue.—J. H. L.

Port wine; Substitutes for genuine ——. So-called Spanish (Tarragona), Grecian, Californian, and Cape port wines. A. Kickton and R. Murdfield. Z. Unters. Nahr. Genussm., 1914, **27**, 617—676. (See this J., 1913, 670.)

Imitation port wines are generally made from completely or almost completely fermented red and white wines which are sweetened by addition of boiled or fortified wine must, and rendered stable by addition of alcohol. Of nearly 600 samples examined by the authors, only three corresponded in composition with normal genuine port wine. On the other hand, some genuine port wines possess a slightly abnormal composition. Imitation port wines seldom contain more than 14·5 grms. of alcohol or less than 0·5 grm. of acid per 100 c.c., and fairly frequently contain 2·5—3 grms. of sugar-free extract per 100 c.c. These values differ appreciably from those previously given for genuine port wines (*loc. cit.*) Further, the imitation wines frequently contain less lævulose than dextrose, the reverse being the case with the genuine samples.—L. E.

The Charpentier thermal ozoniser and its application in the distillery and sugar factory. Sidersky. *See* XIXb.

Patents.

Fermented beverages; Manufacture of ——. E. W. Kuhn, Brussels. Eng. Pat. 11,124, May 10, 1913.

The process described in Eng. Pat. 4622 of 1908 (see this J., 1908, 826) is modified in that the steel container is not completely filled with the liquid to be fermented, the free space being filled with carbon dioxide or other suitable gas under a pressure of 6 atmospheres or more. Part of the requisite gaseous pressure may be produced by forcing additional liquid into the container.—L. E.

Beer containing iron; Preparation of ——. P. Narjes. Hanover, Germany. Eng. Pat. 14,972, June 28, 1913.

Wort containing a high proportion of sugar is fermented in an open vat at 8°—9° C., by about ¾% of thick pasty yeast added in small quantities at intervals during 7—8 days, until about 60% of the extract has been fermented and considerable quantities of lactic acid have been formed. The yeast is then removed and the wort transferred to storage vessels where it is mixed with an excess of iron hydroxide and again treated with small quantities of yeast until all the sugar is fermented and the lactic acid has combined with the iron. Finally the beer is allowed to ferment in closed vessels.—J. H. L.

Wort; Apparatus for extracting ——. W. T. Ramsden, London. Eng. Pat. 18,237, Aug. 11, 1913.

A long perforated rotatable drum, mounted horizontally or nearly so above a trough, serves as a draining and sparging vessel for the mash, which is fed into it at one end and conveyed along it by means of inclined blades or screws fixed to a shaft passing axially through the drum. this shaft rotates in a direction opposite to that of the drum, and is hollow to serve as a duct for the sparge water. At certain enlarged sections of the drum, the mash is thoroughly stirred by the interplay of rods fixed respectively to the drum and the shaft, and the sparge water is injected into the mash at these places, through perforations in the shaft. The drum may be replaced by a perforated trough, in which case an oscillatory angular motion is imparted to the hollow axial shaft.—J. H. L.

Mash-filters; Process for washing the press-cakes in ——. W. Hofmann. Ger. Pat. 272,600, April 5, 1911.

The wash-liquor is passed through a number of press-cakes in succession, and to allow of this being done without using an excessively high initial working pressure, a force pump or other pressure-increasing device is interposed between successive chambers containing the press-cakes. —A. S.

Brewing liquor; Treatment of ——. A. E. Berry and A. Boake Roberts and Co., Ltd., Stratford, Essex. Eng. Pat. 20,712, Sept. 13, 1913.

The brewing water is treated with lactic acid, *e.g.*, about 0·01—0·02% in excess of the quantity required to combine with the alkaline salts present.—J. H. L.

Hops; Process and apparatus for the production of extracts from ——. L. A. von Horst, London. Eng. Pat. 24,813, Oct. 31, 1913.

The hop oil is first extracted by passage of steam through the disintegrated hops, and recovered by condensation; and the dried hops are afterwards enclosed in bags and extracted by boiling once or twice with alcohol and finally with water. The apparatus used for the steaming of the hops comprises a closed vessel communicating with a condenser, and provided with a perforated steam coil at the bottom, above which is a grid supporting a fibre matting to serve as a couch for the hops.—J. H. L.

Malt extracts; Process for removing the bitter taste and burnt smell from ——. E. Cantor, Nurnberg, Germany. Eng. Pat. 5025, Feb. 26, 1914. Under Int. Conv., March 6, 1913.

Steam is passed through the extract, in particular high-dried malt extract, high-dried malt wort, "colour beer," etc., in order to remove bitter or empyreumatic substances. —L. E.

Alcohol manufactured by distilling fermented sulphite liquor; Method of purifying ——. G. Ekström, Harnäs, Sweden. U.S. Pat. 1,095,830, May 5, 1914.

During the distillation the alcoholic vapours are treated with basic substances (*e.g.*, soda solution) capable of binding the sulphurous acid and decomposing the aldehydic compounds present.—J. H. L.

Alcohol; Process of making ——. F. Thatcher, El Paso, Tex., Assignor to L. M. Stiles, Hachita, N. Mex. U.S. Pat. 1,096,965, May 19, 1914.

A mixture of comminuted cacti and water is stirred and treated with superheated steam at 250°—275° F. (121°—135° C.), in a digester. The steam is then blown off, carrying with it formic acid extracted from the cacti. The liquid is expressed from the mass, and treated with ammonium phosphate and with a yeast capable of producing alcoholic fermentation in presence of the remaining traces of formic acid, the fermented liquid being distilled. —L. E.

Fungus; A new —— *and its use in the saccharification of starch and the production of alcohol.* H. Boulard, Paris. Eng. Pat. 25,406, Nov. 6, 1913.

See Fr. Pat. 464,601 of 1913; this J., 1914, 497.—T. F. B.

Producing fermentable sugars [*from cellulosic materials*]. U.S. Pat. 1,096,030. *See* XVII.

Method of utilising and treating the lighter portion of sewage solids. Fr. Pat. 466,387. *See* XIXb.

XIXa.—FOODS.

Cheese ripening: Biochemistry of ——. *Occurrence of p-hydroxyphenylethylamine in normal cheese and its formation by lactic acid bacteria.* F. Ehrlich and F. Lange. Biochem. Zeits., 1914, **63**, 156—169.

All cheeses contain a quantity of *p*-hydroxyphenylethylamine which is produced by the action of micro-organisms on tyrosine; the amine is a normal constituent of cheese and is produced before actual decomposition of the latter takes place. A Swiss cheese, containing 35% of water, yielded 0·06% of the amine. The organisms which produce the substance have been separated: they bear a great similarity to the *Bac. casei* α-, *Freudenreich*, with which they are probably identical. Alcohols and hydroxy acids, such as *p*-hydroxyphenylethyl alcohol and *p*-hydroxyphenyllactic acid, which may be produced by the action of yeasts on tyrosine, are only present in traces, if at all, in ripened cheese.—W. P. S.

Creatine [*e.g., in meat extracts*]; *Colorimetric determination of* ——. E. Baur and G. Trümpler. Z. Unters. Nahr. Genussm., 1914, **27**, 697—713.

The authors investigated the conditions governing the determination of creatine by Jaffé's method, particularly the influence of time, temperature, acid-concentration, etc., on the conversion of creatine into creatinine, and they recommend the following modified method for the determination of creatine in meat extracts: *Creatinine.* Ten grms. of the extract are dissolved in 100 c.c. of water, and

5 c.c. of this solution are mixed with 15 c.c. of a 1·2% picric acid solution and 5 c.c. of 10% sodium hydroxide solution; after 7 mins. the mixture is diluted to 500 c.c. with water at 17° C. and the coloration compared with that shown by a definite depth of $N/2$ potassium bichromate solution. *Creatinine and creatine.* Ten grms. of the extract are dissolved in 100 c.c. of $N/1$ hydrochloric acid, the solution heated for 4 hours to 97° C., diluted to 500 c.c., and 10 c.c., after neutralisation, treated with 15 c.c. of picric acid solution and 5 c.c. of sodium hydroxide solution. The coloration is compared as before, the difference between the two estimations giving the quantity of creatine present. Liebig's extract was found to contain from 0·76 to 5·65% of creatinine and from 1·38 to 5·58% of creatine. Meat extracts prepared by the authors yielded from 7·5 to 8·9% of creatinine *plus* creatine. (See also this J., 1907, 709; 1908, 87; 1909, 737).—W. P. S.

Phytin; Investigation of ——. R. H. A. Plimmer and H. J. Page. Biochem. J., 1913, 7, 157—174.

A *resumé* of previous work is given (see Winterstein, this J., 1897, 1051; Hart and Andrews, 1904, 33; Patten and Hart, 1904, 618; Suzuki and Yoshimura, 1907, 1061; Geys, 1910, 970; Anderson, 1912, 701; Collison, 1912, 742; Contardi, 1912, 1006). The inorganic phosphorus in phytin can be readily determined by precipitation with ammonium molybdate in $N/2$ nitric acid at ordinary temperatures; precipitation is complete in 1—2 days, when the yellow liquid has become colourless, and no hydrolysis of the phytin is to be feared. The calcium cannot be determined by precipitation as oxalate, but accurate results are obtained by precipitation as calcium sulphate in presence of alcohol after oxidation with nitric and sulphuric acids. The magnesium in the filtrate can be estimated subsequently as pyrophosphate. The following figures represent the limits of composition of 8 samples of commercial phytin:—total phosphorus 17·74—20·04, inorganic phosphorus 0·89—0·98, calcium 12·1—12·82, magnesium 0·44—0·81, and loss at 110° C. 6·81—8·52%. It appears that phytin is a calcium salt, the small quantity of magnesium being present as impurity. There is great difficulty in removing the calcium from phytin in the preparation of phytic acid. The yield of inositol obtained when phytic acid is hydrolysed by acids is not quantitative (for inositol hexaphosphate) and the authors consider that another organic constituent may be present. (See also this J., 1914, 371, 436).—J. H. L.

Canadian pure food regulations. Chem. Trade J., June 6, 1914. [T.R.]

A Canadian Order-in-Council, dated April 4 last, lays down certain regulations made in accordance with the provisions of Section 26 of the Adulteration of Food Act. The regulations governing the employment of preservatives apply to foods intended for domestic consumption. Foods intended for export may contain certain preservatives provided that, both in specific character and in amount, such preservatives do not conflict with regulations in force in the country to which export is made.

It is forbidden to add any preservative whatever to milk, or any other preservatives than the following to foods especially intended for the use of infants or invalids: Common salt, saltpetre, wood smoke, vinegar, acetic acid, spices, or alcohol. These preservatives, which are included in Class I, may be used without declaration of their presence provided that such use does not conflict with any other statutory regulations.

Class II. refers to preservatives which may be used until further notice, provided that no more than one kind of preservative substance, named in the list, shall be added to any one kind of food, or to any mixture of two or more kinds of food, that the amount of preservative shall not exceed the maximum amount named, and that the presence of the preservative shall be declared on the label.

Toleration of the use of this class of preservative is dependent upon the fact that available evidence concerning their physiological action is not considered sufficient to prove that under the prescribed regulations they are harmful to health in such a degree as to bring them under Section 3 (*f*) of the Adulteration Act, which reads as follows: "Food shall be deemed to be adulterated within the meaning of this Act if it contains any added poisonous ingredient, or any ingredient which may render such an article injurious to the health of the persons or cattle consuming it." Should satisfactory evidence of the harmfulness to health of any of the preservatives named in Class II. be forthcoming, such preservatives would immediately fall under the condemnation of the Adulteration Act, and foods containing such preservatives would be declared to be adulterated.

(1) Boric acid (boracic acid) or borax. Limit: 1 part in 400 in cream; 1 part in 200 in butter and other foods. (2) Benzoic acid (benzoate of soda). Limit: 1 part in 1,000 parts. (3) Salicylic acid. Limit: 1 part in 5,000 parts. (4) Sulphurous acid (bisulphite of soda, potash, or lime). Limit: 1 part in 10,000 parts in beverages; 1 part in 2,000 parts in solid foods. (5) Saccharin. Limit: 1 part in 1,500 parts in beverages; 1 part in 700 parts in solid foods. (This substance shall not be used to take the place of sugar in any food in which sugar is employed as a source of nutriment, or for its feeding value. Where sugar is used only as a sweetener, saccharin may replace it under the conditions defined above.)

The following preservative substances, included in Class III., are prohibited from use in foods: Formaldehyde (formalin), beta-naphthol, abrastol (asaprol), hydrofluoric acid, fluorides, fluo-borates, fluo-silicates, or other fluorine compounds.

Unsaponifiable constituents of mowrah fat, and detection of mowrah fat in animal and vegetable fats. Berg and Angerhausen. *See* XII.

Patents.

Bread, biscuits and the like; Manufacture of ——. R. W. Dunham, Little Ilford, Essex. Eng. Pat. 2682, Feb. 1, 1913.

Wheaten bran is moistened with an infusion of hops which has been boiled and strained, and when cooled to about 85° F. (29° C.) a quantity of a "sponge" prepared from wheaten flour, water and yeast, is added and the whole well worked together, and left in a warm place for 24 hours. It is then broken up, dried by exposure to air, the bran and fibrous particles removed by means of a sieve, and the screened product used as a yeast food, instead of potatoes, in the manufacture of bread, or alone, as a ferment in the manufacture of biscuits. Or, the kneaded mass may be diluted with water and filtered, and the extract mixed with pure flour by spraying or otherwise. The yeast food, as thus prepared contains an extract from the cerealin cells, on the inner side of the bran, which is of importance for the nutrition of the nervous system.
—E. W. L.

Malt [food] preparations. F. Hoffmann and C. Meerwein, Basle, Switzerland. Eng. Pat. 5001, Feb. 26, 1914. Under Int. Conv., March 3, 1913.

Non-hygroscopic food-preparations are made by mixing calcium caseinate with extract of malt, either in the dry state or in solutions to be subsequently evaporated.
—J. H. L.

Cacao beans; Process of treating —— *applicable to the manufacture of chocolate, cocoa, and cocoa preparations.* L. E. G. Vignes. Fr. Pat. 465,487, Nov. 29, 1913.

Cacao beans are roasted under reduced pressure and the volatile products are condensed and mixed with ground cocoa. Acrid substances which are given off at the commencement of the roasting may be allowed to escape before the subsequent vapours are condensed, or the condensed liquid may be heated to expel these acrid substances.—W. P. S.

Organic substances of animal origin ; Process of dissolving —— and the fixation of their nitrogen in the form of soluble compounds. J. Sloan and E. Bohon. Fr. Pat. 466,150, Feb. 21, 1913.

The organic substance (flesh, etc.) is dissolved in a solution of potassium or sodium hydroxides, the mixture is neutralised with a mineral acid, filtered, and concentrated. Products suitable for use as foodstuffs or as fertilisers are obtained.—W. P. S.

Fish ; Process of treating —— to obtain dried fish and fish guano. E. Bodin, H. Dupont, and M. Riom. Fr. Pat. 466,392, Dec. 19, 1913. Under Int. Conv., Dec. 20, 1912.

Fish are treated with air containing formaldehyde vapour, under pressure at 30° to 100° C., then dried in a current of air at 50° C. The fish may be passed through a disintegrator before being dried, and then ground to a powder. To obtain a fish guano, the treatment with formaldehyde is carried out at above 100° C.—W. P. S.

Milk ; Manufacture of desiccated ——. J. D. Davis, Bridgeport, Conn., U.S.A. Eng. Pat. 21,295, Sept. 20, 1913. Under Int. Conv., Oct. 7, 1912.

See U.S. Pat. 1,070,781 of 1913 ; this J., 1913, 921.—T. F. B.

Flour ; Method of maturing and bleaching ——. J. A. Wesener, Chicago. U.S. Pat. 1,096,480, May 12, 1914.

See Fr. Pat. 465,300 of 1913 ; this J., 1914, 498.—T. F. B.

Process for improving the odour and taste of vegetable and animal fats and oils. Ger. Pat. 273,069. *See* XII.

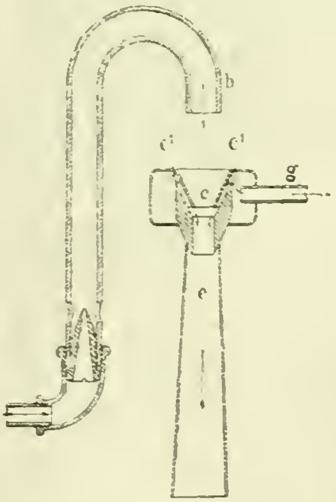
XIXB.—WATER PURIFICATION ; SANITATION.

Lead and copper in drinking water ; Two reliable colorimetric methods of determining ——. C. Reese and J. Drost. Z. angew. Chem., 1914, **27**, 307—312.

A litre of the water is taken, the bottle rinsed with hot distilled water and 2 c.c. of concentrated hydrochloric acid, and the whole evaporated until it can be made up to its original volume with distilled water. Any cloudiness due to ferric oxide must be brought into solution. Finally the hydrochloric acid is neutralised by 4 grms. of crystallised sodium acetate. A standard water of the same colour as the sample but free from lead is treated in exactly the same way and from this a scale is prepared by adding various amounts of standard lead nitrate solution (1 c.c.= 0·1 mgrm. Pb). To 100 c.c. of the water in the colorimeter tube 3 c.c. of acetic acid (10%) are added and freshly prepared hydrogen sulphide solution, or better, sodium sulphide as used by Winkler (this J., 1913, 157). The sample is then compared with the scale in the colorimeter as usual. Copper when present is estimated by the following modification of Winkler's method (*loc. cit.*) using the scale and standard water as above. To 100 c.c. of the water in the colorimeter tube 10 c.c. of a solution containing 100 grms. NH_4Cl and 10 c.c. of pure acetic acid in 500 c.c. are added and, with agitation, 10 c.c. of hydrogen sulphide solution. The total lead and copper is thus estimated. To 100 c.c. of the water are then added 2 drops of 10% potassium cyanide, and, after standing 2 to 3 mins. to allow the copper and ferrous salts to form complex compounds, 10 c.c. of hydrogen sulphide are added and colorimetric comparison made with the scale as before. This reading gives the quantity of lead. The method can only be applied in the absence of ferric oxide, which gives a coloration with cyanide. The above method gave results agreeing within 0·1 mgrm. Pb or Cu per litre. The second method avoids the disadvantage of using a standard ead-free water. It is necessary to use solutions which ave been carefully freed from heavy metals and filtered hrough pure asbestos. The bottle is rinsed out, etc. as n the first method and 20 to 25 c.c. of purified sodium acetate solution (1 : 3), 5 c.c. of glacial acetic acid, a few crystals of sodium sulphide and a little purified asbestos added. If the sample is drawn directly from the tap it is only necessary to add 5 c.c. of glacial acetic acid, 20 c.c. of ammonium nitrate solution (1 : 2), sodium sulphide crystals and asbestos. After standing overnight the precipitate is collected on asbestos, washed with hydrogen sulphide water, dissolved from the filter and from the sides of the flask by means of 20 c.c. of not nitric acid (1 part of acid of sp. gr. 1·4 and 1 of water) and the solution made up to 90 to 100 c.c. with the washing water and evaporated with the addition of 3 drops of concentrated sulphuric acid until free from nitric acid. The lead sulphate is then filtered off on a double paper, washed with dilute sulphuric acid (2 : 100), and dissolved from the filter and the evaporating basin by means of 40 c.c. of hot sodium acetate (1 : 3) solution. 20 c.c. of this solution (corresponding to 100 c.c. of the original water) are made up to 100 c.c. in the colorimeter tube, 2 drops of potassium cyanide solution (10%) added and after shaking well allowed to stand 2 to 3 minutes. Another tube is charged with a corresponding pure sodium acetate solution and treated in the same way, lead having been added to it for the preparation of the scale in the usual way. The copper in the filtrate is also determined colorimetrically. The scale is prepared by adding known amounts of copper sulphate to a solution made to correspond to the filtrate by mixing 3 drops of concentrated sulphuric acid, 40 c.c. of dilute sulphuric acid (2 : 100) and 3 c.c. of concentrated ammonia in 200 c.c. In each case 20 c.c. of solution are made up to 100 c.c. in the tube, 5 c.c. of ammonium chloride solution (10%) added and, after shaking well, 10 c.c. of hydrogen sulphide water. The greatest errors observed were 0·1 mgrm. Pb and 0·11 mgrm. Cu per litre.—J. B.

Ozoniser ; The Charpentier thermal ——, and its application in the distillery and sugar factory. D. Sidersky. Bull. Assoc. Chim. Sucr., 1914, **31**, 747—750.

A gas or alcohol flame is drawn from *b* into the funnel, *c*, by the injector action of compressed air forced in through the pipe, *g*, and annular space, *c′*. The hot gases from the flame are cooled suddenly by admixture with the large volume of air, and the mixed gases leaving *e* are said to contain up to 1 grm. of ozone per cb. metre. Water under pressure may be used instead of air to produce a jet of ozonised water. A portable apparatus on this principle is stated to give good results in sterilising fermentation vats, diffusion discharge waters, etc.—J. P. O.



Water ; Colorimetric determination of iron in ——. F. Gothe. Z. Unters. Nahr. Genussm., 1914, **27**, 676—683.

Contrary to the statement of Heilig (Inaug. Diss. med. Fakult. Heidelberg, 1913), the author finds that in the colorimetric determination of iron with thiocyanate accurate results may be obtained whether the preliminary oxidation be effected with hydrochloric acid and potassium chlorate or with nitric acid, provided the acidity of the solution be low and equal to that of the standard solution, and a large and equal quantity of thiocyanate be added in each case. If 95 c.c. of the iron solution, containing 1 c.c. of hydrochloric acid of sp. gr. 1·125, are treated with 5 c.c. of a 10% solution of potassium thiocyanate, 0·02 mgrm. of iron per litre of water may be determined.—L. E.

Formaldehyde ; Content of methyl alcohol in the vapours produced in the different methods of disinfecting rooms with ——. G. Lockemann and F. Croner. Z. Hyg. u. Infekt.-Krankh., 1914, **77**, 257—281. Chem. Zentr., 1914, **1**, 1772—1773.

On distilling off four-fifths of the volume of a 16% formalin solution, 78·2% of the formaldehyde and 99·5% of the methyl alcohol originally present were volatilised. In the formalin-permanganate process, without lime, 38·3% of the formaldehyde and 79·3% of the methyl alcohol were recovered on distillation. In presence of lime only 12·4% of the formaldehyde was recovered and the quantity of methyl alcohol recovered amounted to 169·1% of that present originally. In the "Autan" process 20% of the paraform used was volatilised as formaldehyde and at least 14·8% was converted into formic acid and methyl alcohol; with paraform and permanganate but no lime, the corresponding figures were 42 and 8·7%, and with paraform, permanganate and lime, 8·6 and 72·3%.—A. S.

Disinfection ; Relations of the phenols and their derivatives to proteins. A contribution to our knowledge of the mechanism of ——. *II. Comparative study of the effects of various factors upon the germicidal and protein-precipitating powers of the phenols. III. Chemical action of quinone upon proteins.* E. A. Cooper. Biochem. J., 1913, **7**, 175—185, 186—196.

The germicidal and protein precipitating powers of phenol are, in general, similarly affected by the entrance of various chemical groups into its molecule, *e.g.*, diminished by hydroxyl groups and increased by nitro groups or by the amino group. The monohydric phenols are superior to the alcohols, both as germicides and as protein-precipitants. Sodium chloride increases the germicidal and protein-precipitating action of phenol, by increasing its solubility in proteins (cp. Reichel, this J., 1910, 107), whilst alcohol has the opposite effect. Solutions of phenol in absolute alcohol or in oil exert no germicidal action upon spores and have no visible precipitating action on gelatin. Very small quantities of alkali inhibit the precipitating power of phenol upon proteins, and moderately low concentrations of alkali effect a measurable decrease in its germicidal power. The precipitating action of phenol is increased by the addition of acids. It is concluded that the absorption of phenols by bacteria is merely the initial stage in the process of disinfection, and that the germicidal action which follows is due, not to a typical chemical union of the phenols with the bacterial protoplasm, as appears to be the case with formaldehyde, but to a de-emulsifying action upon the colloidal suspension of some constituent protein or proteins essential for the vitality of the organisms.

Aqueous solutions of quinone give a red coloration with many proteins, proteoses, amino-acids and imino-compounds. In the case of proteins this reaction appears to be preceded by solution of the quinone in the colloid; no coloration is produced in presence of absolute alcohol, which on account of its great solvent power for quinone would diminish the absorption of the latter by the protein. Formaldehyde, when present in sufficient quantity, completely inhibits the colour reaction (but not in the case of gelatin, aniline or ammonia) probably by combining itself with the amino and imino groups. Acetone differs from quinone in acting as a protein-precipitant. There is some evidence that the germicidal power of quinone is due to its chemical action upon some protein or proteins of the bacterium, and that the superiority of quinone as a germicide, to phenol, quinol and acetone, is explained by its reactivity towards protein at much lower concentrations. —J. H. L.

Lime-sulphur sprays ; Preparation and composition of ——. A. A. Ramsay. J. Agric. Sci., 1914, **6**, 194—202.

The recipes for lime-sulphur washes adopted in various localities vary very greatly (*e.g.*, from 0·88 to 2·08 parts of sulphur and from 10 to 111 parts of water to 1 part of lime by weight). Using the lime and sulphur in different proportions and calculating the amounts entering into solution, the author concludes that the best ratio of lime to sulphur is about 1 to 1·95, and it is suggested that 100 galls. water to 50 lb. of lime with about the above quantity of sulphur will be the most economical recipe. The solution produced on boiling appears to consist of calcium hydroxyhydrosulphide, calcium thiosulphate, and calcium sulphate with sulphur held in solution. —W. H. P.

Bordeaux mixtures ; Further observations on the fungicidal action of ——. B. T. P. Barker and C. T. Gimingham. J. Agric. Sci., 1914, **6**, 220—232.

The authors adduce further evidence in favour of their view of the action of Bordeaux mixture (this J., 1911, 760) which has been opposed by Pickering (this J., 1912, 196). Living cells with readily permeable walls of the unchanged cellulose type are able to render soluble and subsequently absorb copper from insoluble compounds such as the basic sulphates. The effect on the organism depends on the connection between its rate of growth and the rate of absorption of copper. If a fungus is well established and growing rapidly, spraying may fail to check its growth. Cells with walls of an impermeable character have no solvent power. In the case of vigorous apple leaves there is no injury except when the cuticle has been recently injured. Under certain conditions cells with normally impermeable walls may become permeable and absorb copper compounds. Autumn apple foliage for instance is damaged by Bordeaux mixture owing to this cause. The hairs on the under surface of apple leaves, which are decadent cells, will absorb copper even in summer when the epidermal cells (which are full of life) are untouched. It is therefore evident that the nature of the cell is the determining feature in the action of Bordeaux mixture.—W. H. P.

Patents.

Chemical treatment of large quantities of liquid [*water*]. J. J. Lassen and V. F. Hjort, London. Eng. Pat. 13,974, June 17, 1913.

To control the supply of chemicals to a stream of water, a weir is formed in the channel through which the water flows, so that the level of the water above the weir varies with the quantity flowing. A portion of the water above the weir is diverted to a plant where the necessary chemicals are added to it and is then returned to the main stream by a pump which delivers it into a vessel provided with a return overflow to maintain a constant level. The solution flows from this vessel through a valve the size of the opening of which is controlled by float gear from the channel above the weir.—W. H. C.

Water ; Apparatus for removing air from ——. W. Kieser, Berlin, Assignor to General Electric Co. U.S. Pat. 1,095,463, May 5, 1914.

The water passes upwards through a pipe into the lower part of a small chamber, the portion of the pipe in the chamber being expanded into the form of a funnel with walls curving outwards, so that the water is delivered horizontally into the chamber. Separate outlets are provided for the air and the de-aerated water.—W. P. S.

Water; Process of and apparatus for treating ——. C. P. Landreth, Philadelphia, Pa. U.S. Pat. 1,095,893, May 5, 1914.

The water is passed under pressure through a chamber fitted with a series of rotating aluminium electrodes to which alternating and direct currents of electricity are supplied simultaneously.—W. P. S.

Distilled water; Apparatus for the production of ——. B. Bleicken. Fr. Pat. 466,162, Dec. 13, 1913.

An apparatus for the production of distilled water from sea-water consists of a tubular boiler arranged above a furnace, the steam evolved being superheated by the waste gases from the furnace before it enters the condenser. Evaporation is carried out under slightly reduced pressure, and by means of an external return tube, a constant circulation of the water in the tubular boiler is effected. This circulation is aided by the introduction of water from the condenser, a portion of which is admitted to the supply pipe entering the bottom of the tubular boiler whilst another portion is injected into the return tube.—W. P. S.

Water; Process of purifying and clarifying [removing iron and manganese from] ——, particularly potable and industrial waters. O. Vollmar. Fr. Pat. 466,177, Dec. 15, 1913 Under Int. Conv., Dec. 17, 1912, and Sept. 1, 1913.

The water is filtered through material containing algal growths such as *Syderocapsa Dresdensis, S. Treubii, Clonothrix Fusca, Crenothrix Polyspora, Leptothrix Ochracea,* etc.—W. P. S.

Water; Process and apparatus for cooling drinking ——. M. P. Otto and A. Postel-Vinay. Fr. Pat. 466,220, Dec. 16, 1913.

A portion of the water is passed in the form of a spray into a chamber where it is brought into contact with dry air under reduced pressure; the water thus cooled is collected in a vessel containing a coil through which the main volume of the water is circulated. The coil may be constructed of porous material, in which case it is cooled by the current of dry air which is brought into contact with its outer surface.—W. P. S.

Waste-liquids; Purification of —— and extraction of water from sludges. Richter und Richter. First Addition, dated Nov. 11, 1913, to Fr. Pat. 443,789, May 14, 1912 (this J., 1912, 1005). Under Int. Conv., Nov. 15, 1912.

The process described (*loc. cit.*) may be applied to the purification, etc., of oily residues, vinasses, viscous substances, peaty sludges, paper sludges, etc.—W. P. S.

Sewage solids; Method of utilising and treating the lighter portion of ——. J. de la Fresnaye. Fr. Pat. 466,387, Dec. 19, 1913.

The lighter portion of the insoluble substances contained in sewage, and particularly in the waste-water from towns having wood-paved streets, is separated, washed, and hydrolysed by treatment with a mineral or organic acid; the cellulose present is thus converted into dextrins, sugars, etc., which are submitted to fermentation in order to produce alcohol.—W. P. S.

Incinerator for town refuse. P. Auvergne. Fr. Pat. 465,959, Nov. 10, 1913.

The refuse is discharged periodically from a hopper on to rollers situated above a furnace in a closed chamber; while on the rollers, the refuse is dried, and the steam and other gases are conducted round the hopper (containing a fresh charge of refuse) and thence to a condenser. The material falls from the rollers into the furnace and the combustible gases produced are mixed with hot air and conducted to a combustion chamber, the heat from which is utilised to supply a current of hot air to the furnace, etc., or to heat a boiler.—W. P. S.

Smoke, vapours or gases suitable for use in the treatment [sterilisation, etc.] of various materials; Apparatus for the production and treatment of ——. T. G. Marlow, Streatham, and The Pulsometer Engineering Co., Ltd., Reading. Eng. Pat. 9872, April 26, 1913.

The chamber in which smoke or the like is produced by dropping a suitable substance on to a hot band or otherwise, is separated by a movable screen from the chamber in which the material is treated with the smoke. The smoke is carried into the treating chamber by a current of air, for example, as described in Eng. Pat. 16,299 of 1911 (this J., 1912, 909).—W. H. C.

Sterilising liquids and gases by means of ultra-violet rays in vacuum-tubes. E. O. Scheidt. Ger. Pat. 272,772, April 2, 1912.

Tubes of opaque quartz are used which hinder the passage of the inactive visible rays but allow the free passage of the chemically active invisible rays.—A. S.

Vermin; Combustible for destroying ——. A. Lang, Karlsruhe, Germany. Eng. Pat. 20,395, Sept. 9, 1913. Under Int. Conv., Sept. 9, 1912.

Three parts of a mixture of aluminium powder, 9, and sulphur, 16 parts, are added to 1 part of a mixture of charcoal, 3, sulphur, 4, and barium nitrate, 33 parts; shellac solution is then added so as to form a thin paste which is applied to strips of wood or strands of fabric, and dried. The matches thus obtained are ignited in places where it is desired to destroy such vermin as mice, rats, wasps, etc.—W. P. S.

Water; Process for removing oxygen from ——. R. Gans, Grünewald-Berlin, Germany. Eng. Pat. 20,465, Sept. 10, 1913. Under Int. Conv., Sept. 11, 1912.

See Fr. Pat. 462,446 of 1913; this J., 1914, 331.—T. F. B.

Disinfectants; Process for the production of ——. P. Flemming, Hamburg, Germany. U.S. Pat. 1,096,361, May 12, 1914.

See Eng. Pat. 4838 of 1912; this J., 1913, 305.—T. F. B.

Treating fusible domestic and other refuse for obtaining paving or building blocks [and iron]. Eng. Pat. 10,281. *See* IX.

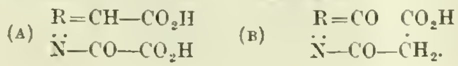
XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Acetylstrychninolone; Oxidation of ——, and preparation of an isomeric strychninolone. H. Leuchs and G. Schwaebel. Ber., 1914, 47, 1552—1560.

Strychninolic acid upon treatment with $N/1$-sodium hydroxide yielded strychninolone, corresponding to brucinolone from brucinolic acid. Acetylstrychninolone when oxidised in acetone solution with permanganate gave rise to a single acid, of which the barium salt, $C_{21}H_{18}O_8N_2Ba$, was isolated. This corresponds to the acid, $C_{23}H_{24}O_{10}N_2$, obtained in small quantities under similar conditions from acetylated crude brucinolone: whence the original strychninolone is held to be analogous to the isomeride of brucinolone present in small amount in crude brucinolone. By treatment with ammonia the original strychninolone changed into an isomeric form. It is concluded that brucinolic acid when treated with alkali yields first an (a) form of brucinolone, which, under the influence of the alkali, changes rapidly into an isomeric (B) form :—

$$\text{(A)}\ \begin{matrix}\text{R=CH—CH}\\ \vdots\qquad\ \vdots\\ \text{N—CO—CH}\end{matrix}\ \rightarrow\ \text{(B)}\ \begin{matrix}\text{R=C=CH}\\ \vdots\qquad\ \dot{}\\ \text{N—CO—CH}_2.\end{matrix}$$

In the case of strychninolone, however, the primary (A) form is the more stable : but in both cases the conversion of (A) into (B) is effected rapidly in presence of ammonia. The above-mentioned acids, $C_{23}H_{24}O_{10}N_2$ and $C_{21}H_{20}O_8N_2$, would thus be derived from the (A) forms ; while the so-called acetylbrucinolic acid, $C_{23}H_{24}O_9N_2$, would be given by the stable (B) form of brucinolone. The acids derived from the two forms differ as shown below :—



$$\text{(A)}\ \begin{matrix}\text{R=CH—CO}_2\text{H}\\ \vdots\\ \text{N—CO—CO}_2\text{H}\end{matrix}\qquad \text{(B)}\ \begin{matrix}\text{R=CO}\quad\text{CO}_2\text{H}\\ \vdots\qquad\quad \dot{}\\ \text{N—CO—CH}_2.\end{matrix}$$

—J. R.

Galegine : Constitution of ——. G. Tanret. Comptes rend., 1914, **158**, 1426—1429. (See this J., 1914, 611.)

Galegine, $C_6H_{13}N_3$, is unsaturated and contains no asymmetric carbon atom. On dry distillation it yields methyl - 3 - pyrrolidine. Benzoylgalegine, $C_5H_9N : C(NH.CO.C_6H_5)_2$ melts at 95°—96° C. Galegine bicarbonate readily condenses with ethyl oxalate to form oxalylgalegine melting at 203°—206° C. When heated with baryta water at 100° C. galegine is quantitatively hydrolysed into methylpyrrolidine and urea.—F. Shdn.

Adonis vernalis ; Constituents of ——. L. Mercier. Nouv. Rem., Jan. 8, 1914, 1 ; Pharm. J., 1914, **92**, 713.

The aqueous extract was treated with lead acetate, filtered, the filtrate treated with basic lead acetate and the precipitate consisting of lead adonidate was suspended in water and treated with hydrogen sulphide. The solid which remained suspended in the liquid was filtered off and extracted with hot alcohol to remove the adonidic acid. The alcoholic extract was evaporated with sufficient hydrochloric acid. The filtrate from the lead adonidate was treated with sulphuric acid, the filtrate neutralised with sodium carbonate and treated with tannic acid solution. The adonidin tannate was then treated with zinc hydroxide and alcohol, evaporated to dryness at 40°—50° C., and the residue extracted with absolute alcohol in a Soxhlet apparatus. Adonidin was obtained by evaporating the alcoholic solution with hydrochloric acid, any adonidic acid separating being filtered off. Adonidic acid gives no colour reaction with sulphuric acid, reduces Fehling's solution and is precipitated and decomposed by bromine water.—F. Shdn.

Squill ; The toxic principle of the ——. W. Kopaczewski. Comptes rend., 1914, **158**, 1520—1522.

Three substances have been isolated from *Scilla maritima.* One has diuretic properties, a second is a polysaccharide, and the third is bitter and extremely poisonous. The last is a light, yellowish non-crystalline powder of distinctive odour, probably a non-nitrogenous glucoside of the formula $C_{17}H_{25}O_6$. It is soluble in aliphatic alcohols, in acetone and in acetic acid and slightly in water. It melts at 152°—154° C.—J. L. F.

Acetylcholine, a new active principle of ergot. A. J. Ewins. Biochem J., 1914, **8**, 44—49.

An active principle of ergot, recognisable by its inhibitor action on the heart and its stimulant action on intestinal muscle, was isolated and identified as acetylcholine.

—J. H. L.

Ephedrine and pseudoephedrine. E. Schmidt. Arch. Pharm., 1914, **252**, 89—138.

Both ephedrine and pseudoephedrine yielded benzaldehyde and methylamine when oxidised with potassium ferricyanide in potassium hydroxide solution. A condensation product, benzalephedrine was formed as a by-product and melted at 72°—73° C. after crystallising from ether. The corresponding benzalpseudoephedrine was not found amongst the oxidation products but was prepared by the interaction of benzaldehyde and pseudoephedrine in the presence of alkali and melted at 65° C. Heating to 205° C. had no effect on either ephedrine or pseudoephedrine hydrochloride. Both hydrochlorides when heated alone to about 240° C. yielded ethylphenylketone (semicarbazone m.pt. 172°—173° C.), methylamine, trimethylamine, and ammonia. When warmed with phosphorus pentabromide, both hydrochlorides yielded the hydrobromide of phenylmethylaminobromopropane, $C_6H_5.CHBr.CH(NHCH_3).CH_3,HBr$, melting at 174·5° C. after crystallising from alcohol and ether, and with $[\alpha]_D = -92{\cdot}79°$ in absolute alcohol. The acetyl compound of this base melted at 175° C. and had $[\alpha]_D = +80{\cdot}0°$ in water. After reduction with zinc and hydrochloric acid, the above hydrobromide gave phenylmethylaminopropane, the hydrochloride of which melted at 172° C. and had $[\alpha]_D = +19{\cdot}14°$ in aqueous solution. Both ephedrine and pseudoephedrine when dissolved in concentrated sulphuric acid and the solution diluted with water after 15 minutes, yielded a substance, $C_{10}H_{15}NO.SO_3$, melting at 244° C., and with $[\alpha]_D = +109{\cdot}02°$. When a solution of ephedrine in chloroform was treated with bromine, ephedrine hydrobromide separated. Pseudoephedrine hydrobromide was also formed in the same way. The two substances are probably optical isomerides.—F. Shdn.

Crocetin. F. Decker. Arch. Pharm., 1914, **252**, 139—160.

Crocetin, $C_{10}H_{14}O_2$, contains one hydroxyl group, the hydrogen of which can be readily replaced so as to form salts with potassium, aniline, etc. It takes up two atoms of bromine with the formation of a yellowish crystalline substance, melting at 103°—104° C. Acetylcrocetin forms red needles melting at about 174° C. A crystalline compound, $C_7H_{10}Br_2O_2$, is obtained by treating an alkaline solution of crocetin with bromine.—F. Shdn.

Phosphorus compounds ; Hydrolysis of organic —— by dilute acid and by dilute alkali. R. H. A. Plimmer. Biochem. J., 1913, **7**, 72—80.

The esters of phosphoric acid are very resistant towards the hydrolytic action of alkalis. Glycerophosphoric acid is completely hydrolysed within 10 days by $N/4$ sulphuric acid at 92° C., phytic acid is not completely hydrolysed in 17 days by $2N$ nitric acid at 75° C., and ethylphosphoric acid is hydrolysed only to the extent of 50% by heating with $N/1$ hydrochloric acid for 20 days at 75° C. These esters undergo hydrolysis more slowly when heated alone in aqueous solution, but they are not appreciably attacked by very prolonged heating with $N/1$ or $2N$ caustic alkali. Hexosephosphate and phosphoprotein differ so markedly from them in their behaviour towards alkalis, as to indicate a different constitution. Hexosephosphate is completely hydrolysed in 24 hours by $1{\cdot}5N$ sodium hydroxide at 75° C., and in 3—5 days by $N/1$ hydrochloric acid at the same temperature, whilst phosphoprotein (see Plimmer and Scott, Chem. Soc. Trans., 1908, **93**, 1699) is distinguished from all other animal organic phosphorus compounds in yielding the whole of its phosphorus as inorganic phosphate when warmed for 24 hours at 37° C. with a 1% solution of sodium hydroxide. In its behaviour towards dilute acids and alkalis, nucleic acid occupies a position intermediate between the stable esters and the very unstable hexosephosphate.—J. H. L.

Lime-juice ; Nitrogenous constituents of ——. C. Fnnk. Biochem. J., 1913, **7**, 81—86.

In an investigation of commercial lime-juice for antiscorbutic substances, the author found small quantities of a crystalline compound, $C_{13}H_{24}O_3$, belonging to the terpene group and melting at 97°—100° C., and relatively minute quantities of three nitrogenous compounds precipitated by phosphotungstic acid, *viz.*, one, $C_6H_7O_2N_5,H_2O$, belonging to the purine group, another, C[illegible]$H_{15}O_6N_2$, belonging to the pyrimidine group, and a third which gave a platinichloride, $(C_8H_{15}O_2N,HCl)_2PtCl_4$

possibly identical with that of the methylpiperidylacetobetaine described by Braun (Ber., 1908, **41**, 2129). No antiscorbutic substance was found.—J. H. L.

Dacryodes hexandra; Oil of ——. Schimmel's Rep., April, 1914, 50—52.

By the fractionation of a large quantity of oil, obtained by steam distillation of the resin of *Dacryodes hexandra*, the presence therein of *l*-sylvestrene, yielding a hydrochloride, m. pt. 68° C., $[\alpha]_D = -21{\cdot}3^\circ$ (in ether solution) has been proved. (See also More, this J., 1899, 718.)—R. G. P.

Frankincense oil. Schimmel's Rep., April, 1914, 62—63.

Frankincense (olibanum) oils at present found in commerce are dextro-rotatory, $\alpha_D = +17^\circ$ to $+29^\circ\ 41'$; formerly the oils were lævo-rotatory, $\alpha_D = -11^\circ$ to -17°. A sample of oil gave the following results:—Sp. gr. at 15° C., 0·8775; $\alpha_D = +19^\circ\ 18'$; $n^{20}_D = 1{\cdot}47245$; acid value, 1·8; ester value, 7·5; after acetylation, 106; soluble in up to 2 vols. of 90% alcohol, solution clear at first but turbid after adding more than 2 vols. of alcohol. The terpene fractions of the oil consisted of nearly 99% of α-pinene and camphene with about 1% of dipentene and *p*-cymene; phellandrene, β-pinene and terpinene could not be detected.—R. G. P.

Neroli oil. Schimmel's Rep., April, 1914, 70—71.

Farnesol, b. pt. 140°—141° C. at 3 to 4 mm. pressure; sp. gr. at 15° C., 0·8934; $\alpha_D = 0^\circ$; $n^{20}_D = 1{\cdot}48991$; was isolated from those fractions of neroli oil boiling above 127° C. at 4 to 5 mm. pressure; the amount of farnesol probably does not exceed 2%.—R. G. P.

Pagsainguin oil. Schimmel's Rep., April, 1914, 73—74.

This oil is derived from *Canarium villosum*, F. Vill. and has been stated by Bacon (Phillipine J. Science, 1910, **5**, 257) to contain *d*-α-pinene, dipentene and formic acid. The sample of oil examined consisted chiefly of *l*-β-pinene, together with *p*-cymene and probably camphene.—R. G. P.

Peru balsam oil. Schimmel's Rep., April, 1914, 80—82. (See also this J., 1914, 565.)

A sample of Peru balsam oil gave the following results: sp. gr. at 15° C., 1·1200; $\alpha_D = +0^\circ\ 55'$; $n^{20}_D = 1{\cdot}57177$; acid value, 36·4; ester value, 228·2; soluble in 0·5 vol. of 90% alcohol. On saponification with alcoholic potash and subsequent steam distillation, benzyl alcohol was obtained at first, and towards the end of the distillation a light oil with a characteristic balsamic odour. After repeated fractionation this gave the following results: b. pt. 125°—127° C. (4 mm. pressure); sp. gr. at 15° C., 0·8987; $\alpha_D = +12^\circ\ 22'$; $n^{20}_D = 1{\cdot}48982$. It was found to be a sesquiterpene alcohol, $C_{15}H_{26}O$, identical with Hesse and Zeitschel's nerolidol (this J., 1903, 162) and with the nerolidol isolated from neroli oil. The peruviol, $C_{13}H_{22}O$, isolated by Thoms (Arch. Pharm. 1899, **237**, 274) from Peru balsam probably consisted of nerolidol, at any rate in part.—R. G. P.

Terpenes; Chemistry of ——. *Action of hypochlorous acid on camphene.* G. G. Henderson, I. M. Heilbron, and M. Howie. Chem. Soc. Trans., 1914, **105**, 1367—1372.

When camphene was treated in the cold with a dilute aqueous solution of hypochlorous acid it was converted almost quantitatively into camphenechlorohydrin, $C_{10}H_{16}Cl.OH$, a colourless crystalline solid, m.pt. 93° C. Treatment with potassium hydroxide or silver oxide converted this into *iso*camphenilanaldehyde, and phosphorus pentachloride converted it into camphene dichloride, m. pt. 139°—140° C. The sole product after heating with zinc and alcohol was *iso*borneol, indicating camphenechlorohydrin to beta-chloroisoborneol. Chromium trioxide dissolved in acetic acid oxidised the chlorohydrin to a chloroketone (chlorocamphor), m. pt. 132° C., which gave an oxime, m. pt. 142°—143° C., and a semicarbazone, m. pt. 220°—221° C.—F. Sodn.

Thymol-menthol emulsoid in glycerin; A ——. J. Don. Kolloid-Zeits., 1914, **14**, 253—255.

Thymol and menthol when mixed together form a liquid at the ordinary temperature unless a very large excess of one component is present. The cryohydric point is —9° C. for a mixture of 2 parts of menthol and 1 of thymol. If a mixture of 100 grms. of glycerin with 5 grms. of thymol and 2·5 grms. of menthol at 80° C. be shaken vigorously and allowed to stand, an upper layer consisting of a liquid mixture of thymol and menthol is formed above a milky liquid composed of an emulsoid of globules of the thymol-menthol mixture (of size ranging from 0·1 mm. downwards) suspended in a solution of thymol (2%) in glycerin; most of the suspended particles are of colloidal dimensions. This milky liquid keeps apparently unaltered for months. Its viscosity is greater than that of glycerin.—A. S.

Cyclohexane; Mercury derivatives of ——. G. Grüttner. Ber., 1914, **47**, 1651—1656.

Cyclohexylmercuric chloride and bromide were prepared by the interaction of cyclohexylmagnesium halide and excess of mercuric chloride or bromide: either of these substances when treated with alcoholic potassium iodide yielded cyclohexylmercuric iodide. By employing about 6 times the theoretically requisite amount of cyclohexylmagnesium bromide, reaction occurred with mercuric bromide with formation of mercury dicyclohexyl, which was freed from cyclohexylmercuric bromide by separation from supersaturated ethereal solutions at 0° C. All these derivatives are much more soluble and far less stable than the corresponding phenyl compounds, and they exhibit strong reducing properties.—J. R.

Glycerylphosphates; Constitution of the ——. *Synthesis of α- and β-glycerylphosphates.* H. King and F. L. Pyman. Chem. Soc. Trans., 1914, **105**, 1238—1259.

The pure sodium, calcium, barium, brucine, and quinine salts of α- and β-glycerylphosphoric acids were prepared synthetically and are described. The commercial crystallised sodium salt, introduced by Poulenc (this J., 1907, 716), is sodium β-glycerylphosphate, whilst the acid prepared by esterifying glycerol with phosphoric acid at 100° C. is mainly the α-compound. The quinine salts of the two acids are readily distinguished by their melting points, the α-salt becoming transparent at 155°—156° C. and only forming a meniscus at higher temperatures, whilst the β-salt melts sharply at 178°—180° C. The brucine salts, however, resemble one another closely, differing only in crystalline form; when dried at 100°—105° C., they are similar as to melting point, sintering at 150° C., becoming transparent at 158°—160° C., and flowing to form a meniscus between 180° and 195° C. Arguments as to the constitution of glycerylphosphates which have been based upon the m. pt. or water of crystallisation of the brucine salt (Paolini, Carré; this J., 1912, 203, 1053) are regarded as valueless.—F. Sodn.

Ethyl acetoacetate; Manufacture of ——. A. Cobenzl. Chem.-Zeit., 1914, **38**, 665—666.

The reaction is carried out in a hemispherical copper vessel of 100 litres capacity provided with a lid and manhole and heated by an oil bath. An upright tube connects the lid with a copper reflux condenser, and a small vessel provided with stopcocks is set between these so that fresh ethyl acetate can be added during the reaction if necessary. The latter should boil at 78°—79° C. and should have no action on clean sodium after two hours' contact at the ordinary temperature. A charge of 5 kilos. of sodium (cut into shavings under xylene) and 40 kilos. of ethyl acetate is placed in the cold copper vessel, the whole mixed with wooden stirrers, and the oil bath slowly heated to 100°—105° C. As soon as the temperature of the contents reaches 45°—50° C., the oil bath is cooled to 55°—60° C. After 30—45 minutes heat is again applied till distillation recommences and is kept up for 5—6 hours. The contents are rapidly transferred to a leaden vessel provided with a stirrer, and mixed with 35 litres of water and the calculated amount of acetic acid. The crude ethyl acetoacetate is then separated and purified by distillation under ordinary or reduced pressure. With careful working the yield is almost quantitative.—F. Shdn.

Niton [radium emanation] as a therapeutic agent. W. Ramsay. Lancet, 1914, **186**, 1481—1483.

For therapeutic purposes the use of niton possesses the advantage that there is no risk of loss of the valuable radium salt. The radiating power of niton is 75% of that of the radium from which it is derived, and its "strength" at any given time can be read from a curve representing its rate of decay. An apparatus for filling with niton, tubes, bulbs or hollow discs of iron or nickel, preferably the latter, is described and illustrated (see Fig. 1). The reservoir, A, from which the air has been previously expelled through M and E, by mercury from B, is placed in communication with the bulbs, H, containing a solution of radium bromide, and the air which passes from the bulbs into A is expelled as before. These operations are repeated three or four times and air is exhausted in a similar manner from the hollow disc or the like, J, which is to be filled with niton. Then after, say, 24 hours the gases (3·6 c.c. from 500 mgrms. of radium bromide) which have accumulated in H are drawn into A, and after raising B, a spark is passed between wires sealed in at D. After exploding, about 0·5 c.c. of hydrogen, carrying the niton, is left and this is allowed to pass into J by turning the tap, G. The vertical tube from J is preferably of thin lead so that it can be sealed by pinching with a pair of pliers. Any gas left above G is drawn back into A by lowering B. If the amount of gas be too large, for example, for filling very fine glass capillary tubes, a small quantity of oxygen (about half the volume of the residual hydrogen) from the tube, K, is trapped by means of mercury in the inverted siphon, E, drawn into A, and a spark again passed, the minute residue then being forced into the capillary tube to be filled, in the manner described above. To recover residual niton from a hollow disc or the like after it has been used, the apparatus shown in Fig. 2 is used, wherein *a* is the piece of rubber tubing shown at I in Fig. 1, *d* is the thin lead tube projecting from the hollow disc, J (Fig. 1), and *b* is a piece of steel with a sharp cutting edge. After exhausting the air by manipulating the mercury reservoir, B, *b* is pushed in so as to cut the tube, *d*, whereupon the niton passes into the reservoir, A. Glass capillaries are introduced into the tube, *c*, and broken by shaking. If gas be "drawn" from 500 mgrms. of radium bromide after 24 hours, 3·6 c.c. are obtained, containing 0·15 of the total amount of niton in equilibrium with this quantity of radium, and as the efficiency of the niton is 75 per cent. of that of the radium, this quantity at the time of "drawing" would be equivalent to 500 × 0·15 × 0·75 = 56 mgrms. of radium bromide. If gas be "drawn" at the end of 12 hours, 1·8 c.c. are obtained containing 0·08 of the total amount of niton in equilibrium with the radium, and hence equivalent to 500 × 0·08 × 0·75 = 30 mgrms. of radium bromide. It is therefore advantageous to make frequent "drawings" of niton from the radium bromide, and this is an argument in favour of a central institution where a large supply of radium could be kept.—A. S.

Fig. 1.

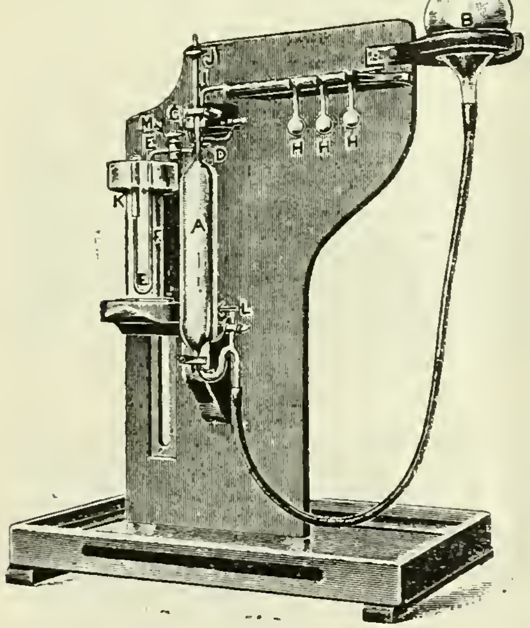


Fig. 2.

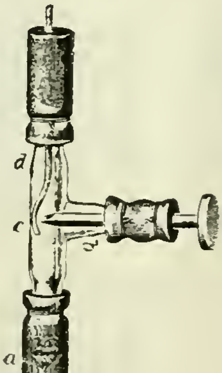

Salts of the fatty acids; Electrolysis of molten ——. J. Petersen. Z. Elektrochem., 1914, **20**, 328—323.

When molten lead, zinc, and sodium salts of fatty acids were electrolysed the products at the anode were similar to those obtained from aqueous solutions, but much smaller in amount. The secondary decomposition of the anode radical was however much more complex and the gases evolved contained (in addition to carbon dioxide) carbon monoxide, hydrogen, olefines, and usually more than one saturated hydrocarbon. The saturated hydrocarbons were mainly ethane and methane. On heating the anhydrous lead salts of the fatty acids with sulphur, the volatile portion consisted of small quantities of gas as above, and a liquid consisting almost entirely of the corresponding fatty acid, together with a trace of the ester (methyl acetate, ethyl propionate, etc.).—W. H. P.

Patents.

Vaccines, cultures, and the like, and the preparation thereof. C. J. H. Nicolle, Paris. Eng. Pat. 26,535, Nov. 19, 1913.

Soluble fluorine compounds are used to "stabilise" vaccines from bacterial cultures or killed virus. The bacteria may be suspended or emulsified in a 0·7% solution of sodium fluoride, centrifuged rapidly, and separated from the solution; the separated mass is again suspended in sodium fluoride solution and centrifuged, and the deposited matter emulsified and diluted to produce the vaccine. The fluorine compound may be rendered insoluble at the time of using, if desired, by adding barium chloride or a salt of lead or calcium.—T. F. B.

Ethyl acetate from acetaldehyde; Preparation of ——. Consortium f. Elektrochem. Industrie, Ges. m. b. H., Nürnberg, Germany. Eng. Pats. 26,825 and 26,826, Nov. 21, 1913. Under Int. Conv., Nov. 27, 1912, and Feb. 21, 1913.

(1.) Acetaldehyde is converted almost quantitatively into ethyl acetate by means of small amounts of aluminium alkyl oxides (alcoholates) in presence of catalytic agents, particularly halides or halogen compounds, such as those of tin, aluminium, and silicon, which are not by themselves capable of forming acetic ester from acetaldehyde. For example, 6 parts of aluminium ethoxide, containing about 10% of aluminium chloride, is added gradually to 135 parts of aldehyde ; after standing for ten hours, the acetic ester (123 parts) is separated by distillation. (2.) Instead of using an aluminium alkyl oxide and another catalyst, the product obtained by treating aluminium alkyl oxide with water or a substance containing water, may be used to convert acetaldehyde into ethyl acetate. The most active of the products of this class appear to be those containing from 16 to 25% Al.—T. F. B.

Halogen derivatives ; Transformation of —— [into aldehydes]. Fabriques de Produits de Chimie Organique de Laire. First Addition, dated Feb. 11, 1913, to Fr. Pat. 452,537, March 7, 1912 (see this J., 1913, 673).

A number of new aldehydes have been prepared by the action of urotropine on monohalogen derivatives, as described in the principal patent ; among them are *m*- and *p*-toluic aldehyde, 3.4-, 2.4-, and 2.5-dimethylbenzaldehyde, *p*-ethyl-, *p*-propyl-, *p*-butyl-, *p*-isoamyl-, and *p*-cyclohexylbenzaldehyde, and methylethyl-, methylpropyl-, and methylbutylbenzaldehyde. The mixed phenol carbonates, such as $C_2H_5O.CO.OC_6H_4.CH_2Cl$, may also be used for the preparation of hydroxyaldehydes.—T. F. B.

Hydroxylamine nitrite and other salts of hydroxylamine ; Process for preparing ——. Toelle und vom Hofe, and J. Kronen. Fr. Pat. 466,070, Dec. 11, 1913.

A solution of a nitrite is mixed with ammonia or an ammonium salt and reduced by means of zinc dust. Preferably 4 parts of sodium nitrite and 3·1 parts of ammonium chloride are dissolved in 50 parts of water, and 3 to 4 parts of zinc dust is slowly added, with stirring : a solution of hydroxylamine nitrite is obtained.—T. F. B.

Glycerol-halogenhydrins and polyhydroxy-fatty acid esters ; Process for preparing ——. A. Grün. Ger. Pat. 272,337, July 23, 1912.

Triglycerides of hydroxy-fatty acids are treated with the calculated quantity or with excess of hydrohalogen acid in the gaseous form or dissolved in alcohol, under pressure; the glycerides may be used in the form of a solution. The principal products from castor oil are glycerol mono- and dichlorhydrins and esters of polyricinoleic acids. The yields of chlorhydrins amount to 90 to 98%, whilst the polyricinoleic acids are obtained in theoretical quantity.—T. F. B.

Albumin with alkaline-earth or heavy metal phosphates, sulphates, and silicates ; Process for preparing compounds of —— soluble in alkali. W. Wolff und Co. G. m. b. H. Ger. Pat. 272,517, July 18, 1912. Addition to Ger. Pat. 253,839 (see this J., 1913, 47).

Albuminoids, albumoses, peptones, or their halogen substitution products are treated in aqueous alkaline solution with an alkali phosphate, sulphate, or silicate and a soluble salt of an alkaline-earth metal (other than calcium) or of aluminium, chromium, zinc, lead, bismuth, copper, silver, or tin ; the complex albumin compound is separated from the resulting solution by neutralising with a small quantity of acid, by adding ammonium sulphate or sodium chloride, or by precipitation with alcohol or acetone.—T. F. B.

Arylcarbamic acid esters ; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 272,529, Jan. 9, 1913.

Alkylamines are treated with derivatives of arylcarbamic acids, or aliphatic amines are treated with halogenalkyl esters of arylcarbamic acids. The products are powerful anæsthetics.—T. F. B.

Halogenated CC-dialkylbarbituric acids ; Process for preparing ——. A. Einhorn. Ger. Pat. 272,611, Nov. 27, 1912.

CC-Dialkylbarbituric acids are heated with halogens under pressure, preferably in presence of an indifferent organic diluent. The resulting halogen compounds contain the halogen in the alkyl groups. They are soluble in dilute alkali carbonates and in ammonia, and may be used for the preparation of soporific agents.—T. F. B.

Mercury paranucleinate with alkalis ; Process for preparing compounds of ——. Knoll und Co. Ger. Pat. 272,687, Jan. 21, 1913.

Mercury *p*-nucleinate is dissolved in alkali and the solution treated with alcohol, or *p*-nucleinic acid is neutralised with an alkali and the solution is treated with mercuric chloride and alcohol. The products are easily soluble in water, giving neutral solutions suitable for therapeutic injection.—T. F. B.

Mercury paranucleinate with tannin ; Process for preparing compounds of ——. Knoll und Co. Ger. Pat. 272,688, Jan. 21, 1913.

Compounds of mercury *p*-nucleinate with tannin are obtained by treating the mercury salt with a solution of tannin, or by dissolving mercury *p*-nucleinate in alkali and treating with a solution of tannin, or by treating sodium *p*-nucleinate with mercuric chloride solution and tannin solution.—T. F. B.

Dihydroxybenzene-arsinic acid ; Process for preparing a ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 272,690, Dec. 14, 1912.

m-Dihydroxybenzene-arsinic acid is obtained by heating resorcinol with arsenic acid.—T. F. B.

Cyanhydrins of aldehydes and ketones ; Process for preparing derivatives of ——. A. Albert. Ger. Pat. 273,073, July 30, 1912. Addition to Ger. Pat. 259,502 (see this J., 1913, 673).

Selenium compounds, analogous to the sulphur compounds described in the principal patent, are obtained by treating acylated cyanhydrins with hydrogen selenide. They may be used in medicine.—T. F. B.

Acetic anhydride ; Process for preparing ——. Act.-Ges. f. Anilinfabr. Ger. Pat. 273,101, Jan. 16, 1912.

A good yield of acetic anhydride is obtained by passing chlorine into a mixture of an acetate and a chlorine compound of sulphur ; the temperature should not be allowed to rise above about 20° C.—T. F. B.

p-Aminophenyl ester of salicylic acid ; Process for preparing derivatives of —— containing sulphur. J. Abelin, E. Bürgi, and M. Perelstein. Ger. Pat. 273,221, May 18, 1913. Addition to Ger. Pat. 268,174 (see this J., 1914, 220).

The *p*-aminophenyl ester of salicylic acid is treated with an alkali or ammonium salt of ω-methyl-, ethyl- or propylsulphonic acid in presence of methyl or ethyl alcohol ; it is preferable to add a condensing agent, such as sodium acetate. The alkylsulphonates are obtained in almost quantitative yield and in a state of purity.—T. F. B.

Salts of lower fatty acids ; Process for preparing a mixture of ——. J. Ederer. Ger. Pat. 273,271, May 27, 1913. Addition to Ger. Pat. 272,036 (see this J., 1914, 568).

Vegetable matter other than wood, such as dry fallen leaves, nut-shells, etc., are extracted with dilute alkaline solutions, either at the ordinary temperature or at higher temperatures and pressures, in a diffusion battery, and the liquor is evaporated. The yields of lower fatty acids obtainable from beech leaves and hay by this process amount to 4% of the weight of the air-dry material. —T. F. B.

Cupric salt of cholic acid ; Process for preparing the ——. Knoll und Co. Ger. Pat. 273,317, April 18, 1913.

SOLUTIONS of cupric salts are treated with sodium cholate in presence of methyl or ethyl alcohol ; cupric cholate is obtained in a pure, compact form, which can easily be dried, whereas when the reaction is carried out in aqueous solution the product is obtained as a voluminous, gelatinous mass which it is difficult to dry.—T. F. B.

Bromodialkylacetamide ; Process for preparing derivatives of ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 273,320, April 18, 1913.

BROMODIALKYLACETAMIDES are treated with formaldehyde in presence of a condensing agent, to produce N-methylol compounds, of the composition, $RR_1CBr.CO.NH.CH_2OH$, where R and R_1 represent alkyl groups. The products possess strong hypnotic and sedative properties.—T. F. B.

Alkyl- and arylaminomethylalkyl ethers ; Process for preparing ——. E. Merck. Ger. Pat. 273,323, Jan. 23, 1913.

ONE mol. of a halogenmethylalkylether is brought to reaction with two mols. of an aliphatic or fatty-aromatic primary or secondary amine, preferably in presence of an indifferent organic solvent. The products have the general formula, $alkyl.O.CH_2.NRR_1$, where R represents alkyl or aralkyl and R_1 hydrogen or alkyl : they may be used in the preparation of medicinal products, such as hydrastinine. —T. F. B.

Panama bark ; Treatment of —— for preventing the production or separation of dust therefrom. R. Mandelbaum, and Dr. A. Kauffmann und Co., Asperg, Germany. Eng. Pat. 21,862, Sept. 27, 1913. Under Int. Conv., Sept. 27, 1912.

SEE Ger. Pat. 264,163 of 1912 ; this J., 1913, 1031.—T. F. B.

Chlorinated aromatic or cyclic compounds ; Manufacture of ——. Fabriques de Produits de Chimie Organique de Laire, Issy les Moulineaux, France. Eng. Pat. 30,068, Dec. 31, 1913. Under Int. Conv., Jan. 17, 1913.

SEE Fr. Pat. 464,645 of 1913 ; this J., 1914, 503.—T. F. B.

Acetaldehyde ; Process of preparing ——. E. Baum and M. Mugdan, Assignors to Consortium f. Elektrochem. Industrie G. m. b. H., Nuremberg, Germany. U.S. Pat. 1,096,667, May 12, 1914.

SEE Fr. Pat. 455,370 of 1913 ; this J., 1913, 959.—T. F. B.

Ethyl acetate from acetaldehyde ; Process for preparing ——. Consortium f. Elektrochem. Industrie G. m. b. H. Fr. Pat. 465,965, Nov. 20, 1913.

SEE Eng. Pats. 26,825 and 26,826 of 1913 ; preceding. —T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Silver bromide-gelatin plates ; The simultaneous development and fixation of ——. C. Otsuki and T. Sudzuki. Mem. Coll. Sci. and Eng., Kyoto Imp. Univ., 1914, 6, 25—28.

THE combined developing and fixing solution proposed by Crémier (Phot. Rev., 1911, 170), containing 1 grm. of amidol and 2·5 grms. of thiosulphate in 100 c.c. of water, does not give images of sufficient density, and requires from 37 to 40 minutes to act completely. The authors tried to prepare an amidol solution which would work more rapidly, by increasing the amounts of amidol and thiosulphate, but the images were still too thin. Similarly with metoquinone and sodium sulphite and carbonate it was impossible to obtain sufficient density. However, it was found that the use of caustic soda instead of carbonate resulted in a rapidly acting solution which gave satisfactory images. The best formula is, metoquinone, 0·6 grm. ; anhydrous sodium sulphite, 3 grms. ; caustic soda, 0·5 grm. ; sodium thiosulphate, 6 grms. ; water, 100 c.c. In this solution the image is completely developed in 60 to 90 seconds at a temperature of 18° to 22° C. It is best to make the metoquinone and sulphite into one solution and the caustic soda and thiosulphate into another, and to mix the two at the time of using.—T. F. B.

PATENT.

Tellurium toning bath for photographic silver images. Chem. Fabr. auf Actien, vorm. E. Schering. Ger. Pat. 272,162, Jan. 1, 1913. Addition to Ger. Pat. 271,041 (see this J., 1914, 503).

DEVELOPED and fixed "gas-light" prints are toned pleasing bluish-grey shades by using solutions of tellurium in alkali sulphite.—T. F. B.

XXII.—EXPLOSIVES ; MATCHES.

Explosion ; Circumstances attending an ——, which occurred on Feb. 20, 1914, in an incorporating house in the factory of Nobel's Explosives Co., Ltd., at Ardeer, Ayr. Major. A. Cooper-Key, H.M. Chief Inspector of Explosives. [Cd. 7396.]

EIGHT men were killed as the result of an explosion of 4180 lb. of blasting gelatin and gelignite in a building, 43 ft. by 25 ft., constructed of wood, in which were eight incorporating machines. The machines had two vertical revolving gunmetal spindles, each carrying 12 horizontal blades, in three sets of 4, the blades of one spindle being about ½ inch below the corresponding blades of the other. There was ample clearance between the ends of the blades and the sides of the pan containing the explosive. In the Inspector's opinion the accident was probably due to some action on the part of one of the men engaged in charging the machines, and the only loose article which could possibly fall into the machines, during the operation of loading, would seem to be a thin sheet-lead apron employed to prevent spillage during the transference of the thin jelly from the box to the pan. Three "runners" were among those killed. The erection of a simple form of shelter against the outer slope of the mound and clear of the tunnel would be an additional factor of safety for "runners." Attention is drawn to the probable advisability of isolating incorporating machines in separate compartments, divided by concrete walls, but the Inspector is not prepared to make a definite recommendation on this point. The incorporating machines were driven by a line of shafting level with the ceiling. In the present case one portion of this shafting, 21 ft. in length, was found half buried in the ground, and another piece, 15 ft. long, was dug out of the mound protecting a danger building. This source of danger would be obviated by the use of two separate shafts, one on each side, situated outside the building and sunk level with, or below the level of, the floor.—G. W. McD.

Smokeless powders ; Experiments upon the ignition of large quantities of —— at the Russian Powder Factory at Schlüsselburg. A. Saposchnikow. Z. ges. Schiess- und Sprengstoffw., 1914, 10, 187—190, 217—219.

NITROCELLULOSE powder, either in the form of strip or tube from 2 to 3·6 mm. in thickness or diameter, was

ignited electrically by the aid of a fuse of fine grain gunpowder contained in a cylinder of gelatinised nitrocellulose. There were no actual explosions of the powder in the following instances. A heap of one ton lying in the open, when ignited from the outside, took 25 secs. to burn out completely, and there was a flame from 20—25 m. high. A similar heap when ignited in the middle took 22 secs. to burn out. 1½ tons laid out in a train 18—20 m. long and 50 cm. high, and ignited at the windward end, took 49 secs., and when ignited at the opposite end 103 secs. to burn out. 1½ tons placed in a large box burnt at about double the rate of the same powder when ignited in the open. One ton of powder was sealed up in 5 cases and these were placed in a strong wooden box with 1½ tons of loose powder lying round the cases. From 5—10 secs. after ignition of the loose powder the whole was blazing very fiercely with a flame about 40 m. high. About ½ min. later, when the flame from the loose powder had died down, one of the cases burst into flame, and, later, two others. Two of the cases were recovered with the whole of the powder in them, but it showed very marked signs of decomposition. 10 tons of powder were placed in a wooden house on tables about one metre apart. The layer of powder on the tables was 75 cm. thick. Four secs. after ignition the flames attained a height of 130 m. and the whole burnt out in 33 secs. The rate of burning was about 12 times that in the open. In the following instances the smokeless powder actually exploded instead of burning. When open cases of black powder and smokeless powder were placed together and ignited. When black powder was present and the sealed lining of cases containing smokeless powder was defective. When a shell containing 5 lb. of trinitrotoluene was detonated on top of a case of smokeless powder. The explosion was communicated to adjoining cases.
—G. W. McD.

Patent.

Explosive substances. C. Claessen, Berlin. Eng. Pat. 24,839, Oct. 31, 1913.

See Fr. Pat. 463,714 of 1913; this J., 1914, 376.—T. F. B.

XXIII.—ANALYTICAL PROCESSES.

Ferrocyanides; Determination of —— by oxidation with an alkali bromate. L. L. de Koninck and N. Joassart. Bull. Soc. Chim. Belg., 1914, **28**, 144—148.

Under specified conditions ferrocyanides can be quantitatively oxidised by bromates in acid solution:

$$6K_4Fe(CN)_6+KBrO_3+6HCl=$$
$$6K_3Fe(CN)_6+KBr+6KCl+3H_2O,$$

and the method can be utilised for the determination of ferrocyanides using iron alum as external indicator. The solution is acidified with hydrochloric acid and at the end of the titration the concentration of free acid should be about $N/1$; variations from this strength greater than 10—15% render the results too high. The method gives accurate results agreeing with those obtained by using permanganate as oxidising agent; and no ions capable of precipitating the unchanged ferrocyanide are introduced into the solution, as is the case with permanganate.

Patents.

Pyrometers. H. L. Heathcote and Rudge-Whitworth, Ltd. Fr. Pat. 465,898, Dec. 8, 1913. Under Int. Conv., June 16, 1913.

The object the temperature of which is to be judged is viewed through a layer of coloured liquid contained in a vessel having transparent ends and a flexible body, and held between two annular plates kept apart by a spiral spring. The flexible body allows the distance between the plates to be varied without altering the capacity.
—W. H. C.

Liquids; Apparatus for the continuous examination of ——. O. Friese, Berlin, and F. Graafen, Erfurt, Assignors to Hydro-Apparatebauanstalt J. von Geldern und Co., Düsseldorf, Germany. U.S. Pat. 1,096,832, May 19, 1914.

See Ger. Pat. 233,529 of 1910; this J., 1911, 714.—T. F. B.

XXIV.—MISCELLANEOUS ABSTRACTS.

Fluorine in soft waters. A. Gautier and P. Clausmann. Comptes rend., 1914, **158**, 1389—1395. (See also this J., 1914, 280.)

A method capable of determining less than 0·1 mgrm. F. per litre consists, essentially, in carrying down the fluoride by the precipitation of barium sulphate, which is subsequently treated with sulphuric acid, the fluorine being finally converted into lead fluoride, and the lead determined colorimetrically as colloidal lead sulphide. The results of the examination of a number of natural waters by this method show that their fluorine content varies from 0·6 mgrm. per litre in the case of the R. Vilaine, draining plutonic and metamorphic rocks, to 0·01 mgrm. for the Lake of Geneva, whose waters are partly calcareous, serving to precipitate the fluoride in the presence of soluble phosphates.—J. L. F.

Boron in mineral waters. H. Fonzes-Diacon and Fabre. Comptes rend., 1914, **158**, 1541—1542.

The boron-content of various mineral waters was investigated by the colorimetric method of Bertrand and Agulhon (see this J., 1914, 105, 273). It seems to depend, to some extent, upon the temperature, varying from 0·05—0·07 mgrm. per litre for the Royat group, and rather less for the Vichy group, to less than 0·005 mgrm. in cold mineral waters.—J. L. F.

Dispersoid [colloidal] solutions; Processes which occur on shaking —— with liquid and solid substances practically insoluble in the dispersion-medium. P. von Weimarn and A. Alexejew. J. Russ. Phys.-Chem. Ges., 1914, **46**, 133—135. Chem. Zentr., 1914, **1**, 1627.

Contrary to the statements of Salbom (Kollo'dchem. Beihefte, 1911, **2**, 79) and Zsigmondy (Kolloid-Zeits., 1913, **13**, 105), it was found that all colloids in aqueous media, even those with a negative electric charge, are coagulated by sufficiently prolonged shaking with liquids insoluble in water. An aqueous colloidal gold solution was coagulated by toluene, bromobenzene, oil of turpentine, salol, diphenylamine, brucine, iodoform, copper oleate, acetic anhydride, ether, petroleum spirit, chloroform, and petroleum; a colloidal gold solution in glycerin by toluene, chloroform, and petroleum spirit; an aqueous alcoholic colloidal barium sulphate solution by toluene and oil of turpentine, and an aqueous colloidal ferric hydroxide solution by oil of turpentine.—A. S.

Books Received.

The Fixation of Atmospheric Nitrogen. By Joseph Knox, D.Sc., Lecturer on Inorganic Chemistry, University of Aberdeen. Gurney and Jackson, 33, Paternoster Row, London, E.C. 1914. Price 2s. net.

Volume (7½ ins. by 5 ins.), containing 103 pages of subject-matter, 6 of bibliography, and an alphabetical index. There are seven illustrations. The text is classified as follows:—I. Fixation of atmospheric nitrogen as nitric and nitrous acids, or as their salts. II. Synthesis of ammonia and ammonium compounds from atmospheric nitrogen. III. Conversion of atmospheric nitrogen into compounds which readily yield ammonia.

Instructions for Rearing Mulberry Silk-Worms. [Agricultural Research Institute, Pusa.] Bulletin No. 39, 1914. By M. N. De. Member of the Sericulture Assoc., Japan, etc. Calcutta: Superintendent Govt. Printing, India. 1914. Price 4 annas, or 5d.

Pamphlet (9¾ ins. by 7¼ ins.), containing 25 pages of subject-matter with 8 illustrations. The text is classified thus:—(I.) Introduction. II. Appliances for rearing. III. Eggs. IV. Rearing. V. Temperature and humidity. VI. Silk-worm diseases. VII. Pasteur system of selecting disease-free eggs. VIII. Grasserie. IX. Facherie. X. Muscardine (all three, diseases). XI. Reeling. XII. Mulberry, and its diseases, etc. XIII. Silk washing. XIV. Silk dyeing, with acid colours, basic colours, alizarin colours, and vegetable colours. XV. Weaving. XVI. Advice and information.

Lectures on Explosives. By William Macnab. [The Institute of Chemistry of Great Britain and Ireland.] 30, Bloomsbury Square, London, W.C. 1914. Price 2s. 6d.

Two lectures delivered before the Institute, the first on February 26th, 1914, and the second on March 26th, 1914. They fill 67 pages, and contain 19 illustrations. The classification of matter is as follows:—I. Historical sketch of manufacture and use of explosives. II. Detonators, and their use and scope. III. Character of explosive decompositions. IV. Two modes of explosion:—(*a*) Combustion or deflagration. (*b*) Detonation. V. Velocity of explosion wave in detonated explosions. VI. Conditions for foreseeing explosions, and interferences necessitating experiment, also experimental limitations. VII. Heat developed, etc. VIII. Explosion heats; attempts at measurement. IX. Sensitiveness, etc. X. Qualities explosives should possess. XI. Testing explosives. XII. Governmental rules and regulations (Home Office) for construction and working of factories. XIII. Processes and plant. XIV. Military propellants. XV. Sporting powders. XVI. Fiery coal mines and explosives (Home Office). XVII. Filling for shells. XVIII. Novel application of explosives. XIX. Scope of chemists' work with explosives.

The Gas Chemists' Summary, 1913. By A. V. Hendrickson, Chemist to the South Suburban Gas Company, etc. Walter King, 11, Bolt Court, Fleet Street, London, E.C. 1914. Price 3s. 6d.

Volume (8½ by 5½ ins.), containing 107 pages of subject matter, with Bibliography of 8 pages, and an alphabetical index, also a few illustrations. The classification of subjects is as follows:—I. Carbonisation. II. Condensation, washing, purification, and naphthalene extraction. III. Tar and ammonia. IV. Oil gas and carburetted water-gas. V. Photometry and calorimetry. VI. Gaseous heating and ventilation. VII. Gas analysis. VIII. Tests. IX. Miscellaneous.

[Monographs on Biochemistry.] Alcoholic Fermentation. By Arthur Harden, Ph.D., D.Sc., F.R.S., Professor of Biochemistry, London University, etc. [2nd edit.]. Longmans, Green & Co., 39, Paternoster Row, London; Fourth Avenue and 30th Street, New York; Bombay, Calcutta, and Madras. 1914. Price 4s. net.

Volume (9⅝ by 6¼ ins.), containing 135 pages of subject matter, with 7 illustrations, 19 pages of Bibliography, and an alphabetical index of subjects. These monographs are edited by R. H. A. Plimmer, D.Sc., and F. G. Hopkins, D.Sc., F.R.S., and the present volume contains a general preface by the editors. The classification of the matter is as follows:—I. Historical introduction. II. Zymase and its properties. III. The function of phosphates in alcoholic fermentation. IV. The Co-enzyme of yeast-juice. V. Action of some inhibiting and accelerating agents on the enzymes of yeast-juice. VI. Carboxylase. VII. The by-products of alcoholic fermentation. VIII. The chemical changes involved in fermentation. IX. The mechanism of fermentation.

Birmingham Section.

Meeting held at Birmingham University on Thursday, May 7th, 1914.

MR. H. T. PINNOCK IN THE CHAIR.

DISCUSSION ON FUEL—GASEOUS, LIQUID, AND SOLID.

Professor John W. Cobb (Leeds), in opening the discussion, said that when such a fuel as coal was burned completely, the same amount of carbonic acid and water was always formed, and the same amount of heat generated, but the amount of heat utilised depended on a number of considerations, and called for skill in the design and use of apparatus. Moreover, coal was not simply a potential source of so many heat units but was a chemical substance capable of yielding other chemical substances of considerable commercial value on its way to carbon di-oxide and water if the process were controlled. That was the reason for the existence of many fuel problems, and, particularly, modern fuel problems. If coal were burned in one stage the smoke problem had to be faced. The existence of the smoke nuisance might be said briefly to be due to this particular fact: that although distillation and oxidation of coal could both go on at low temperatures the distillation reached a high velocity at a comparatively low temperature, at which combustion was very slow. Another problem arose from the difficulty of using large quantities of fine dust coal. The dust below ground was a danger, and the most effective means of securing that it should be brought out was to make its economical use possible. Dust-firing for boilers and furnaces was fortunately making some headway.

A practical method of dealing with the smoke problem was to effect the combustion of coal in more than one stage; in one, the coal was gasified, in the other, the gas was burned. A blast of air used below a deep layer of glowing coal half-burned it to what was known as producer gas, which could be taken away and burned completely where desired; it contained the nitrogen of the air-blast and so was called low-grade gas. If the coal were only heated, without contact with air, as in gas retorts, or coke ovens, the gas contained very little nitrogen and was a high-grade gas. The advantage of producer gas was made obvious to certain industries by the introduction of the important principle, for fuel users, of regeneration. As soon as gaseous fuel was used it became possible to design apparatus in such a way that some of the heat leaving furnaces in the products of combustion, was restored to the gas and air entering. Thus the open hearth steel process became a commercial possibility. A higher point of efficiency was attained and the use of higher temperatures became feasible. The process of regeneration was necessary for high temperatures with producer gas, but ceased to be of the same importance with high-grade gas. The significance of that was best understood when one attempted to design a small scale apparatus using the regenerative principle.

There was also the difficulty in applying the regenerative principle to small furnaces that the expense of construction would be prohibitive, and the cost of renewal of complicated working parts too great. The possibilities of producer gas were much increased as soon as another disadvantage was removed. For delicate work there should be a proper control of the flow of gas and air, and the regenerators, ports and passages should remain unfused, and be free from dust. A considerable step was made in the development of producer-gas engineering and furnaces when it became economical, on a large scale, to wash producer gas. That was effected successfully by the introduction of a plant the primary purpose of which was the recovery of ammonia.

Dr. Mond found that by the use of a large quantity of steam it was possible to get half of the nitrogen—a proportion since increased—as ammonia. Under that process about 2½ lb. of steam were required for every pound of coal, and a considerable amount of that steam went through the producer undecomposed, so that to establish a high degree of thermal efficiency it became necessary to recover the latent heat of the large quantity of steam escaping through the producer. It was this which led to the system of washing towers, by which the gas was sent away washed and cooled. It could then be controlled and distributed in small pipes; and the most delicate ware could be exposed, if necessary, to the full action of the gas without danger from coal ash. A claim had recently been made that the same high ammonia results could be obtained with a smaller quantity of steam in the blast essentially by water-jacketing the top of the producer; but he thought that those who had had much to do with the ammonia recovery process would require a stricter and narrower definition of the claim made before accepting its probable validity.

Ammonia recovery introduced a new problem since ammonia, when it was recovered in producer-gas, coal-gas or coke-oven practice as ammonium sulphate, required that sulphuric acid should be brought to it, and that had to be bought or made. Interest, therefore, attached to any process which would do away with the necessity of providing sulphuric acid, especially in plants erected in somewhat inaccessible places abroad. The sulphur was in the coal. The ammonium sulphide was in the gas, and by the simple addition of oxygen one got ammonium sulphate. The addition of the oxygen was not a process as simple as it appeared, but several processes were on trial for doing it.

If no oxygen were used in gasifying coal most of the carbon remained as coke, the rest going forward with other constituents as permanent gas, and as vapours. Until recently there were two established methods for working that sort of process. If town gas were required it was made in retorts; if coke were the primary product desired it was made in a coke oven. Modern developments were tending to unify the science and practice of carbonisation to this extent—that it would be more necessary in the future to consider carefully local conditions and markets, and decide what modification of plants, or what combination of them, was most effective. The old horizontal retort was being, to some extent, replaced by the vertical retort, in which gravitation was used to save labour, and continuous vertical retorts were another development. Processes were also being tried and worked in which the temperature and the conditions of carbonisation were even further altered from the normal. One object was to make a coke which ignited easily and burned cheerfully. If a low temperature of carbonisation was used only a portion of the volatile matter was driven off from the coke—the part most likely to produce smoke, such a substance was coalite. A disadvantage of low-temperature coke was that it was rather soft for carriage, and there was a difficulty in controlling the distribution of temperature in a retort working at low temperatures; it was apt to be irregular. In low-temperature carbonisation it was not only the coke which was altered, but the gas was richer, and the tars and oils which came out and condensed were lighter. This was now a point of great importance, because of the large and increasing use of motor traffic and internal combustion engines generally. The demand had arisen for an increased supply of an oil or spirit which was easily and completely volatilised in a current of cool air, and could be used in a carburettor. One way of meeting the difficulty was to design a new carburettor working on a less volatile oil. Another way was to work out a process by which a mixture of oils of different densities, such as a crude petroleum, could be altered in chemical nature so as to contain a much higher proportion of volatile oils. Work in both these directions was being prosecuted vigorously. A third way which would increase the supply although not to the extent sometimes stated was to carbonise coal so as to yield a large supply of light oils. In the coalite process that was done by using a lower temperature, but processes were also being tried using higher and lower pressures. It was not of course correct to say that high benzene yields resulted from low temperatures; as a matter of fact, the volatile oils produced were more like petrol itself.

Whether coke or gas, or both, were burned, we should be freed from the smoke nuisance; but the gas industry was handicapped by a system of selling gas at a price too far above that of its manufacture and distribution. That policy had been defended as a definite means of indirect municipal taxation. It was a tax placed upon the home-manufactured article, and the competitor, raw coal, was out of reach of the imposer. In effect, it placed a premium upon the wasteful use of fuel and pollution of the atmosphere.

Dr. W. B. **Davidson** said he was strongly in agreement with Professor Cobb in suggesting that coal should be brought into disuse as much as possible, in favour of coke and gas. From eight years' personal experience he could say that it was quite an easy matter entirely to displace coal in one's house. If he were on the City Council he would make it his business to bring forward a resolution that a byelaw be made prohibiting the use of coal unless it could be burned without smoke. Something drastic was necessary. The great objection to ordinary good gas coke was the difficulty of ignition because it contained only one or two per cent. of volatile matter. With a coke of 5 or 6 per cent. there was no difficulty in ignition. He was glad that Professor Cobb hit out against municipalities who contributed to the rates from the gas profits. It was a great mistake not to reduce the price of gas to the lowest point. There was, he added, a tremendous wastage of fuel even in gas works where huge quantities of coal were dealt with. In Birmingham the amount required in heating the retorts was 100,000 tons and that amount could be cut down by the simple device of controlling the primary air as by Brooke's air regulator. At one of the city gas works the fuel consumed had been reduced from 25,000 tons to 16,000 tons per annum—a saving of 9,000 tons, or an equivalent of £5,000. If that were done in the whole of the Birmingham gas works there would be a saving of 35,000 tons, or nearly £20,000 per annum

Mr. **Cooper** stated that the production of metallurgical coke was about 11 million tons per annum, of which not more than 65 to 70 per cent. was produced in a scientific way. Taking a coal which had 30 per cent. of volatile matter from this coal when carbonised in the modern coke oven the yield of coke would be approximately 70 per cent. With the same amount of coal utilised in the old type of oven there would probably not be more than 55 to 60 per cent. of coke. In addition with the bye-product oven one got 5,500 cubic feet of surplus gas, about 30 lb. of sulphate of ammonia, 10 gallons of tar and 2½ gallons of benzol. In the case of the beehive oven one got nothing but the coke. It will be seen, therefore, that if all the coke were made in bye-product ovens there would be an enormous saving amounting to some millions of pounds per annum. In Germany greater progress had been made in this respect than in this country, as was shown by the figures for the production of sulphate of ammonia. The rapid increase in production was due to the total adoption of bye-product coke ovens in place of those of the beehive type. There were over 3,000 beehive ovens in Yorkshire, over 4,000 beehive ovens in Durham and several others in other parts of the country. He thought it could be safely said that every class of coal which was coked at all could be dealt with in bye-product ovens. This was especially important also from the point of view of the production of gaseous fuel.

Birmingham had taken the lead in another development, namely, the adoption of chamber ovens for gas production, and these had led to a big saving of fuel on account of the fact that the ovens were heated by producer gas which could be made from inferior fuel and the nitrogen could be recovered from these in the form of sulphate of ammonia. He was very sceptical as to the claims made in relation to the results of low temperature carbonisation. An interesting development of this system of carbonisation which was to be worked on a Yorkshire Colliery was a combination of the Coalite process with gasification of the resulting coke in gas producers. The private Company working this scheme had realised the difficulty they might be faced with when it came to getting rid of the smokeless fuel and they had, therefore, adopted the idea of gasifying this in producers and recovering the ammonia. The surplus gas was to be sold to an electric power company for the production of electricity. On a coke oven plant the surplus gas was used for boiler firing purposes and in some cases in gas engines. Its value on the colliery for boiler firing purposes as compared with coal on the calorific value basis was about 2d. per thousand cubic feet.

Mr. H. T. **Pinnock** pointed out that it was the application of the regenerative and recuperative principle that brought prominence and position to producer gas. This principle was easily applied, and it was that circumstance which made it possible for producer gas to compete with higher power calorific gas for high temperature furnace use. As to the question of abstracting the sulphur from producer gas he agreed that such a course was most desirable both from the point of view of making sulphuric acid and to facilitate certain kinds of work in which sulphur was injurious. Finality had not been reached in regard to producer gas and he thought it was likely to develop to that end on the lines of reduced steam consumption for making ammonia. He thought there would be difficulty, if it was a producer of large size—of from 10 ft. to 11 ft. diameter—to cool the interior of it sufficiently, merely by outside water jacketing. Another way in which producer plants might be expected to improve was in the more centralised extraction of tar. That was the bugbear of many plants which had to work in limited places. The tar had to be extracted at various places in cooling, and the colouring matter therefrom often found its way into the canals and drains, and caused conflict with the local authorities. As to the firing of coal dust, the Bettington boiler struck him as ideal from the point of view of fuel consumption. He did not altogether like the idea of small and long tubes working at high rates, owing to scaling, which often meant the scrapping of the tubes. If such tubes were employed the proper softening of the water had to be very carefully attended to.

Mr. W. J. **Rees** was of opinion that progress must be along the lines of the recovery of the by-products, particularly in gas-producer work. The serious question presented was the immense capital expenditure necessary in laying down recovery plants with works using large quantities of coal. It was also necessary to aim at the further removal of dust and of sulphur from producer gas; and if that could be economically achieved without resort to by-product recovery the advantage would be considerable to many industries, and to the glass industry in particular. With some fuels it was possible to keep some of the sulphur out of the producer gas by sprinkling the fuel with milk of lime, but this method was not really satisfactory in any way. As to the coal-dust problem it was possible that much of the dust could be used by mixing with tar, and using in briquetted form.

The London County Council insisted upon purchasin coal only on a calorific value basis. There were adopte four standards—calorific value, moisture, ash content, an price. Deductions were made *pro rata* if the fuel wer below the standards agreed to in the contracts, an correspondnig bonuses paid if the fuel were above th standards.

Mr. E. J. **Guild** (Leek) stated that his firm, who we paper manufacturers in North Staffordshire, were relucta to adopt mechanical stokers or patent furnaces. In ord to avoid smoke they insisted on sending up an excess of ai and he asked if low temperature coke would be of use them. He also mentioned that his firm would not co sider the use of oil or gas as fuels. His difficulty along had been to induce them to use coal in a more economical way.

Dr. W. B. **Davidson** stated that not the least difficulty would be experienced in burning coke in a Lancashire boiler—and, of course, there was no smoke.

Mr. W. B. **Parker** commented strongly on the fact that there was no recognised standard of purity for coal washed and sold for boiler purposes. The ash approximated from 10 per cent. to 25 per cent. It seemed to him that the consideration, prior to that of the scientific utilisation of fuel, was whether efforts should not be directed to secure that colliery owners would supply fuel of higher quality. He suggested that what was necessary was a central authority for the fixing of a quality standard for each pit. A reasonable specification as to percentage of ash was wanted.

Mr. E. W. **Smith** (Birmingham), said it was startling to hear that coal gas could be produced even at a colliery at 2d. per 1000 cubic feet. No doubt it could be made in the retort house at that figure, but then all the charges for carriage, coal handling and purifying the gas, and for distribution, must be added. Birmingham prices were extremely low, having regard to the rates in many other towns, so that manufacturers had the advantage. The aim must be to obtain the highest efficiencies in securing the greatest amount of heat from the original fuel, and also from the apparatus in which it is to be used. Until recent years it had not been possible to obtain economical results in heating processes, but now, as a result of improvements in the design of furnaces, the cost compared favourably with that of solid fuel furnaces and oil furnaces. He had no faith in the claims made for "surface combustion" at high temperature, nor with the results obtained. Although he had seen large apparatus working under the so-called new process, he had seen nothing, either in boilers or furnaces, practicable, or likely, efficiently, to last. The scientific explanations given with regard to surface combustion—in which there was nothing new either in the form of combustion or the type of furnace employed—were unnecessary and unsatisfactory. Interest would centre on an experiment, shortly to be made on the lines of low temperature carbonisation, by a large firm of continuous vertical retort makers. They were about to install a plant in the Midlands for experiments on those lines mainly with a view to producing hard coke and large volatile oil yields. In the Birmingham Gasworks fuel was being used in what appeared to be an ideal way. The volatile matter was driven off from the coal; the coke was then put into producers and was gasified, and gas was made from this product with which the retorts were heated. This method gave the further advantage of enabling them to obtain by-products in sulphate. A drawback in the use of producer gas for industrial purposes lay in the fact that it contained a large amount of sulphur compounds. That was an almost insuperable stumbling-block in many processes. In the new Corporation plant experience showed that the tar was materially reduced by the centrifugal extractors before the sawdust scrubbers were reached. He did not see why it should not be possible to use coal dust when low in ash in coke ovens compressed with water. The coke would be useful for small furnace work f the ash content was not too high. A coke of high porosity burned much more easily than ordinary gas coke, and ignited immediately from chips.

Mr. F. R. **O'Shaughnessy** stated that he was interested n two of the by-products of the gas industry, viz., nitrogen and tar. The nitrogen in coal had an interesting biological ignificance, for its presence there instanced in a most triking manner the extraordinary stability of certain kinds of nitrogenous organic matter when subjected o destructive putrefaction. If one considered that he vegetable matter from which this nitrogen came nderwent decay for an indefinitely long time when the emperature at the earth's surface was probably much igher than now, the presence of so much residual nitrogen n the coal now was almost startling. In promoting estructive putrefaction of similar organic matter on the arge scale which was present in sewage sludge he was ruck very much by the resistant character of the nitrogenous bodies, and next to mineral matters they were the most resistant normal constituents of the sludge.

He would like to recommend this fact to the notice of enthusiasts who lamented the loss to agriculture entailed by our present methods of sewage disposal. The loss was not nearly so great as they imagined, for the bulk of the nitrogen was not available, and in fact the only way to make it available was to subject the dried sludge, like coal, to destructive distillation. By co-operation with the local gas officials experiments were to be made by him and them on making "producer" gas from the dried sludge with recovery of the nitrogen as ammonium sulphate. The other by-product to which he referred, viz., tar, had a melancholy interest for him as a sewage expert. Certain portions of the tar were until recently not commercially recoverable as they existed in the form of an emulsion, and not infrequently this aqueous residue found its way into the sewers and produced disastrous effects if allowed to enter the sludge digestion tanks. He was very pleased indeed to hear that this useless by-product might be used for making briquettes, etc., and he hoped the gas experts would be able to recover the whole of this tar and prevent it exerting its baneful influence on the biological operations at the sewage purification works.

Professor **Cobb**, in reply, said as regarded tar extraction and ammonia recovery in producer-gas plant, centralisation would simplify the cooling process, but he was doubtful as to air-condensers being applicable to large plants. The difficulty of cooling depended upon the fact that the thermal capacity was so enormously increased by the latent heat of the steam present. Calculations he had made on surface cooling gave discouraging results for a plant of any size. He agreed that a careful choice or treatment or both of water for such a boiler as the Bellington would be necessary. One difficulty of using coke oven gas in regenerative furnaces was the considerable loss in actual heating power, when the gas passed through the regenerator, on account of the decomposition of hydrocarbons. Mixing with blast-furnace gas was reported to be successful. He agreed that the coke oven process might deal satisfactorily with dust of certain qualities. Ash could not be determined accurately without very careful sampling because so much was concentrated in the smaller coal, and, particularly, the dust. He agreed that the question of purchasing coal, on standardised lines, would assume greater importance in the future.

Meeting held at Burlington House on Monday, June 8th, 1914.

PROF. W. R. HODGKINSON IN THE CHAIR.

SOME STUDIES ON THE REDUCTION OF URANIUM OXIDE.

BY ERIC K. RIDEAL, PH.D., B.A.

Within the last two years several investigators have published papers drawing attention to the constant accumulation of uranium salts as by-products of the radium industry. The general idea of all is to draw attention to the necessity of finding (in the near future) some technical applications for uranium or its salts.

The use of the oxide to produce a yellow glaze in ceramics, and also a yellow opalescent glass, has long been known; and although this glass is of an expensive nature, up to 20% of uranium oxide being frequently added to produce a good colour, the consumption of uranium by these industries is not enough to absorb all the oxides at present available. It must be remembered that about one ton of pitchblende yields less than 0·2 grm. of radium, and the market for uranium colours is not expanding. Photographic work also consumes a certain amount of the supply. The uranous salts are effective reducing agents.

but appear to be more expensive to work with than the titanous compounds which have been extensively used in the trades.

Metallic uranium and uranium carbide have not been well investigated on account of the difficulties of preparation. It would appear, however, that if a method of manufacture were devised which produced this metal as economically as the more easily reducible tungsten, chromium or molybdenum it would prove an asset if not a valuable adjunct in many industrial processes. In an anonymous article in the Oest. Zeit. f. Berg. u. Huttenwesen, 1909, we are informed that uranium increases the tenacity of steel, and, although not quite as good as vanadium, chromium, nickel, or tungsten for general purposes, it is specially suitable for cannon metal, and armour plates. Frank L. Hess (U.S. Geol. Survey, 1911) records that uranium steel is very similar to tungsten steel but at the present time very much more expensive. Further investigation is needed to confirm these statements. Uranium carbide mixed with oxides has been used for the cores of arc electrodes as a source of ultra-violet light, while the metal and carbide are said to have been used in the production of gas mantles and electric filaments, although on account of the relatively low melting point of the metal the utility of the latter is not at once obvious. Possibly the carbide or an alloy of uranium and iron would be used as a substitute for "cereisen" in automatic pipe lighters and so on. Moreover, it furnishes a direct method of conversion of coal and probably gas coke into the more useful liquid hydrocarbons; but at the present time the method has no more than a scientific significance. The finely divided metal is even more efficient than osmium as a catalyst for the conversion of hydrogen and nitrogen gas mixtures into ammonia.

The following is an account of an investigation into the various methods of producing uranium from its salts; these methods are divisible into two classes.

1. Production from uranous salts.
2. Production from the black-green uranium oxide U_3O_8.

1. *Production of uranium from uranous salts.*

(a) Preparation of dry uranium tetrachloride.

Many methods have been suggested for the preparation of this salt from the oxide.* The following method gives good results.

Uranium oxide and sugar are heated together in absence of air to form an intimate mixture of carbon and the oxide, which is then heated to a low red heat in a current of chlorine saturated with carbon tetrachloride vapour. Crystals of the salt mixed with pentachloride sublime on to the cooler parts of the tube. Copper salts exert a little catalytic activity, but are removed by sublimation of crystals of a double salt UCl_42CuCl in the form of long golden brown needles. On redistilling the mixed chlorides in a current of dry CO_2, the tetrachloride is obtained in a state of purity.

(β) *Preparation of the metal from the chloride.*

According to Zimmermann [Ber. XV., 1182, Ann. 216, XIV. (1883)] uranium may be obtained as a black powder and as solid metal by reduction of the tetrachloride by sodium in the presence of sodium chloride. These experiments were repeated in a steel cylinder of the form shown in Fig. 1.

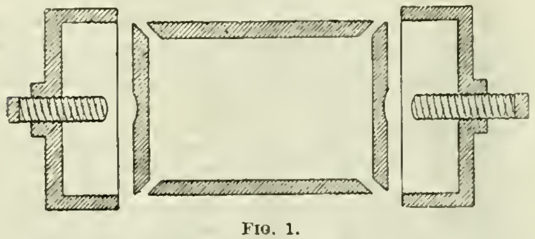

FIG. 1.

A mixture of 10 grms. UCl_4 with 4 grms. sodium and 4 grms. NaCl are heated to 800° C. in a resistance furnace for 45 minutes. The cylinder is subsequently cooled in oil, opened and washed out with alcohol and water; a brown powder containing 99·3% of uranium is obtained. Zimmermann's statement that melted uranium is obtained by this method has not been confirmed. The method has been investigated since these experiments were made in greater detail by A. Roderburg [Zeit. Anorg. Chem. LXXXI. (1913)], who has shown that the steel cylinder under the action of the sodium contributes varying amounts of iron to the uranium, and that uranium is not obtained molten under these conditions. Substitution of magnesium for sodium and of uranium tetrafluoride for the tetrachloride yielded less satisfactory results.

Electrolysis of uranium tetrachloride solutions. According to Ferée (Bull. Soc. Chim. [3], 622) uranium amalgam can be obtained by the electrolysis of an aqueous solution of uranium tetrachloride using a mercury cathode. The uranium is obtained by distilling off the mercury in vacuo. I repeated this method with a 5% UCl_4 solution and obtained a red liquid containing UCl_3 (Loebel, Ueber Halogenverbindungen des Urans. Dissert., Berlin, 1907), and a black deposit which contained both mercury and uranium. Only a very small quantity of uranium was recovered from the mercury; alterations in the current density, temperature, and concentration of the solutions did not markedly affect the result.

As a general conclusion the preparation of uranium from uranium salts does not appear feasible from the industrial point of view.

2. *Production of uranium from urano-uranic oxide* (U_3O_8).

This oxide is the usual article of commerce, and is therefore the most suitable for use as a raw material for direct reduction. With A. Fischer (Zeit. Anorg. Chem. LXXXI., 170, 1913) I have shown that pressed urano uranic oxide possesses a distinct electrical conductivity its sp. resistance at 18° C. lying between 2702 Ohms/cm and 2705 Ohms/cm.

The following curves showing the relationship betwee current, temperature and applied electromotive forc indicate that the conductivity is pseudo-metallic at lo

* Zimmermann, Ber. 1938 (1881). Lothar Meyer, Ber. 181 (1887). Camboulevis C.R. 150, 175. A. Colani, Ann. Chem. Phys. (8) 12, (1907).

E.M.F.'s and afterwards electrolytic in character, a somewhat remarkable phenomenon in a coloured powder.

The decomposition voltage between platinum electrodes is 7·0 volts. The rapid increase of the conductivity with the temperature suggests the possibility of electrolysis in the solid state in an atmosphere of hydrogen, the liberated oxygen being removed as fast as it is formed. The form of apparatus is evident from the appended figure.

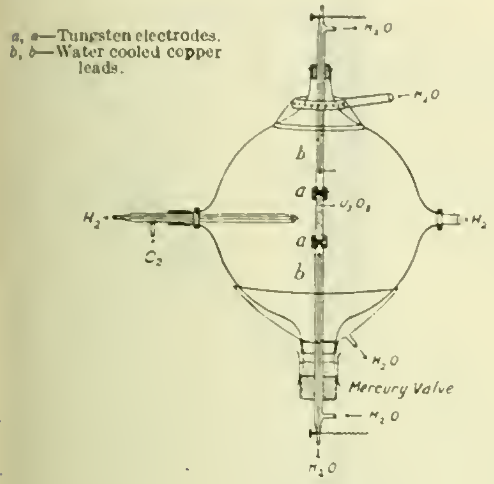

FIG. III.

Tungsten electrodes must be used, since when carbon ones are used much carbide is formed. The pressed oxide in the form of a rod mounted between the tungsten electrodes is heated by the oxy-hydrogen flame: when warm the oxygen was burned off and the heating continued for one hour at a temperature of 1200° C. by means of the current in a hydrogen atmosphere. Analysis of the resulting product yields: U 89·5%; UO_2 contains 88·2%.

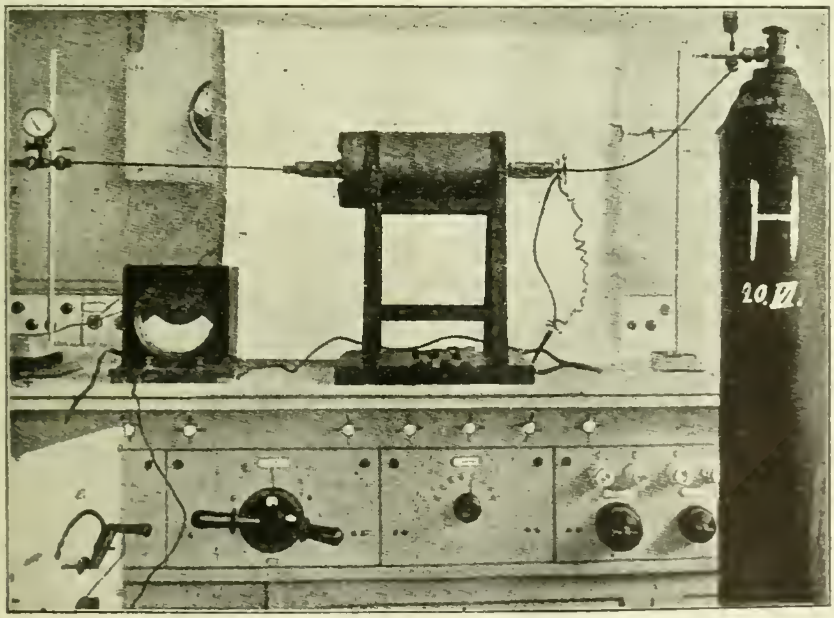

FIG. IV

The product is black, of a well-defined crystalline character, and easily soluble in strong nitric acid with the evolution of nitric oxide fumes.

Since indications have been obtained of reduction by means of hydrogen under normal pressures it seemed worth while to attempt the reduction by this gas under pressure.

Accordingly a special furnace was designed and constructed for the purpose.

The furnace consisted of an iron shell 100 mm. internal and 178 mm. external diameter 300 mm. long turned out of the solid. One end of this cylinder was an integral part of the whole, while the lid, 39 mm. thick, was attached by 8 screws, each 17·5 mm. in diameter. A gas-tight joint between cylinder and lid was obtained by means of a copper asbestos ring. The inside was lined with asbestos paper.

The heater was constructed of a porous porcelain cylinder wrapped with platinum wire, which was embedded in a paste of a mixture of precipitated alumina with a trace of magnesia. When the paste had set it was covered with asbestos paper and iron sheathing. Thick platinum leads insulated by quartz tubes and asbestos discs were brought through the lid of the furnace, the asbestos discs being tightly compressed by cone-shaped check nuts. The leads for a pyrometer were brought through in a similar manner. By this artifice the heating unit could be taken out at will for repairs or replacement.

Admission and escape for the hydrogen was provided by weldless copper tubing brought through the lid and end of the furnace respectively. With a current of 10 amperes at 220 volts, a temperature of 1000° C. could be maintained for prolonged periods, while a slow current of hydrogen, controlled by Desaga valves, at 100 atmospheres pressure was continually passing through the apparatus The oxide U_3O_8 however could not be reduced further than UO_2 under these conditions.

Experiments were then made on the possibilities of applying the "Thermite" process to this reaction. According to Aloy (Bull. Soc. Chim. 25, 344) and Stavenhagen (Ber. 32, 1899) magnesium or aluminium powder will reduce the oxide U_3O_8 to metal of 96%—97% purity. On repeating Stavenhagen's experiments only a regulus of magnesia or alumina with uranium dioxide and metallic magnesium was obtained. It appeared that the temperature of the mixture did not rise high enough to complete the process of reduction unless sufficient air was present, which of course permitted the uranium metal to re-oxidise.

Finally an electro-thermal thermite process was adopted which yielded excellent results :—

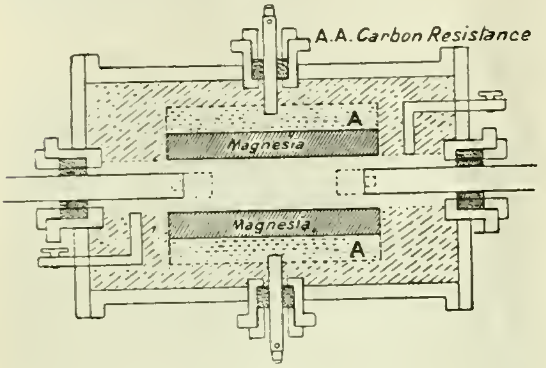

FIG. V.

Briefly the apparatus consisted of a resistance combined with an arc furnace. The granular carbon resister was used to heat up a tube of pure magnesia which contained a mixture of 80% U_3O_8 and 20% magnesium powder pressed into the form of solid rods by means of an oil press. The ends of the rods in the magnesia tube were placed in contact with carbon electrodes, and a current of hydrogen was passed through the apparatus. When hot enough they became conducting and the main electrodes were connected to the 110 volt mains which caused an arc (at a current of 30—40 amperes) of magnesium vapour to play in the centre of the magnesia tube. The magnesium vapour effectively reduced the uranium oxide to metal.

The hydrogen had to be displaced by carbon dioxide before the finely divided "uranium black" could be exposed, since the fresh metal spontaneously ignites in the air. The magnesia could be separated by washing with dilute acetic acid; this did not seriously diminish the yield of uranium. Analysis yielded 98—99% metal.

Reduction of the oxide may also be brought about by magnesium powder and sodium in the presence of calcium chloride as a catalyst.

A mixture of 50% U_3O_8, 15% $CaCl_2$, 15% Mg. 20% Na, was heated in a small steel cylinder to a bright red heat. After being cooled in oil the cylinder was opened and washed out with alcohol, weak acetic acid, and water; the product was a powder grey black in colour and contained 99·4 to 99·6% metal with traces of iron.

Reduction with carbon.

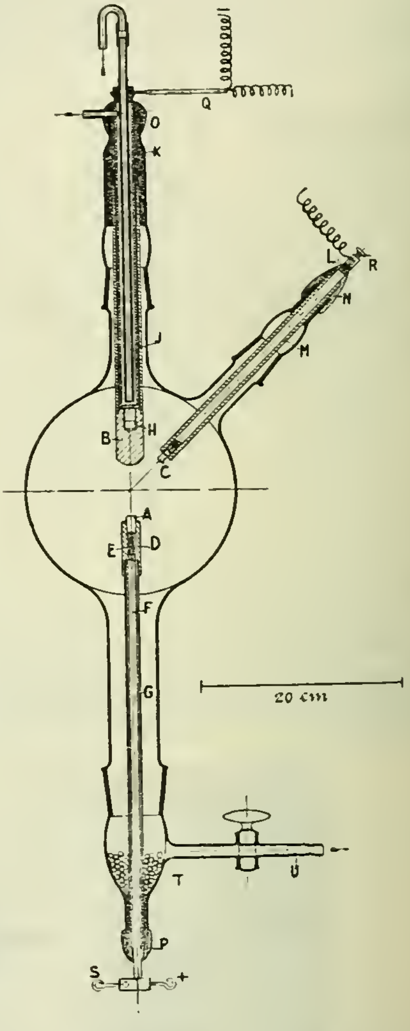
According to Moissan [C.R. 122 (1896), 1088] and Moxter [Zeit. Anorg. Chem., 78, 231, (1912)] uranium oxide is reducible to metal of varying purity by carbon in the arc furnace, when proper precautions were taken. Uranium is technically made by this method and varies in purity between 96 and 98% metal (0·1% deficiency is equivalent to roughly 1% uranium carbide as carbon).

On a small scale it was found that even this state of purity could not be obtained. Professor Hodgkinson's method of using calcium carbide might yield more favourable results.

Fusion in vacuo.

The m.pt. of uranium containing 0·4% carbon lies between 1300° and 1400° (uncorrected). The apparatus used was Roderburg's modification of Wartenberg's vacuum furnace (Ber. 40, 3287, and Zeit. Anorg. Chem., LXXXI., 1913), which, as it probably has a future in industrial chemistry, is described below.

The apparatus consists of a glass globe of about 3 litres capacity with three carefully ground-in tubular attachments. The lower one holds the anode A, a short rod of tungsten metal surrounded by a magnesia tube D and a quartz tube B; the rod is attached to the lead F, a brass rod fixed in the end of the tubular attachment by means of sealing wax. The upper tube is water cooled and carries a massive tungsten cathode B coated with the oxides of barium and calcium. The small electrode C serves as an auxiliary electrode.



The apparatus is evacuated to 0·01 mm. of mercury and an alternating current is sent through B and C (th voltage necessary varies between 2000 and 4000). Th electrode B emits white hot particles which permit direct current of only 100 volts pressure between th electrodes A and B to arc across.

The main drop of potential and consequently th maximum heat formation occurs at the surface of the smal anode A which shortly begins to melt. The point of fusio is determined by an optical pyrometer.

It is evident that A may consist of any metal provide it is in the form of a short conducting rod.

The author devised a modification of the apparatu for the fusion of powders or non-conducting solids.

The small tungsten electrode A is replaced by a annular one containing a small magnesia crucible fitte with a magnesia block lid. An apparatus of this siz can be made to take a crucible of about 2 c.c. capacit

A similar apparatus can be constructed of metal (*e.g* copper) provided that due precautions are taken f insulation. By setting the electrodes A B horizont instead of vertical, and feeding the electrode A by mea of a worm as required, considerable amounts of metal fuse in vacuo may be obtained.

Meeting held on Friday, January 23rd, 1914.

MR. G. W. THOMPSON IN THE CHAIR.

THE INVENTION OF CELLULOID.

The following remarks were made by Prof. C. F. Chandler on the occasion of the presentation of the Perkin Medal to Mr. Hyatt (see this J., March 16, 1914, pp. 225—229), and were omitted from the published report :—

I should not take up your time by enlarging further on the history of celluloid were it not that in one of our most important and most recent works on applied chemistry I find it stated as follows under the head of celluloid :—

"The substance was first produced by Daniel Spill of Hackney, England, and came into commerce under the name of Xylonite.

"Spill's method of converting the nitrocellulose has been followed for more than forty years."

I have had occasion, in connection with celluloid and nitrocellulose litigation, to study most carefully the history of the pyroxylin industry, and there is no logical ground for making the above statement. Celluloid was invented by the brothers Hyatt, and not by anyone else. This whole matter has been thrashed out in the Federal Courts as long ago as 1886, and the Hyatt patents have been sustained, although everything that had been patented or published was carefully studied and discussed during the litigation.

It is quite true that many other experimenters sought to prepare useful plastic compounds with the aid of pyroxylin prior to the Hyatt invention of celluloid. Most prominent among these experimenters we find Alexander Parkes and Daniel Spill, but neither one of them ever suggests the essential features of the Hyatt method for manufacturing celluloid. Parkes' patents relate to the following points :—(1) Making liquid solutions by the use of various solvents, rendering the material less inflammable by adding chloride of zinc or tungstate of soda or gelatin dissolved in acetic acid. (2) Making sheets by pouring the solution on glass and allowing it to evaporate. (3) Dehydrating wood alcohol or naphtha as a solvent by distilling over chloride of calcium. (4) Adding castor or cottonseed oil, gums or resins, or oil previously treated with chloride of sulphur to the solvents. (5) Introducing nitrobenzene or glacial acetic acid or hydrocarbon solvents.

In one patent he proposed to remove the solvent from the solution of pyroxylin by adding water, mineral naphtha, or other liquids. In another patent he gives compositions to be used as varnish.

There is nothing whatever in any one of these patents that anticipates Hyatt.

As for Daniel Spill, his patent 2666 of 1867 suggests as substitutes for dehydrating alcohol or wood naphtha as a solvent for pyroxylin, fish, vegetable oils, essential oils, resins, gum resins, spirits of turpentine, fats, light oils and naphtha from coal and mineral naphthas.

One example of a suitable solvent contains 80 per cent. alcohol and 20 per cent. of rosin. Another contains 60 per cent. of alcohol, 3 of castor oil, 1 of essential oil of lavender, 3 of resin and 34 of coal naphtha or benzol.

The Spill patent 3984 of 1868 claims the production of compounds of Xyloidine by the employment of non-volatile solvents, mentioning animal, fish, vegetable, or mineral oils, as mineral tar, lard oil, cod liver oil, camphor oil, or liquid camphor, linseed oil or heavy coal oils or mixtures of the same. He further states that the following substances may be added: paraffin, camphor, resins, fat, wax, india rubber, gutta percha or balata gum or mixtures of the same. He gives the following example :—

Camphor, camphor oil, or liquid camphor	20 parts by weight.
Oil, such, for example, as castor or linseed oil, either before or after such oils have been oxidised or boiled	40 parts by weight.
Xyloidine..............................	40 parts by weight.

The claim of the patent is for the production of compounds of Xyloidine by the employment of non-volatile solvents.

This is also the essential feature of the claims of Spill's American patents 91,377 and 91,378 in 1869.

Spill took out another British patent 3102 of 1869, substantially identical with U.S. Patent 97,454 of the same year. This does not differ materially from his prior patents. He mentions a great variety of solvents, many of them mentioned in his previous patents and these he groups under eight numbered paragraphs and gives the following as the only example of his invention :—

Xyloidine..............................	27 parts by weight.
Castor oil	27 parts by weight.
Camphor	6 parts by weight.
Solvents, either of the Nos. 1, 2, 3, 4, 5, 6, 7, 8	40 parts by weight.

The Spill patent 180 of 1870 is for bleaching Xyloidine. His patent 787 of 1870 and his U.S. patent 101,175 of 1870 are for the employment of evaporating and concentrating apparatus, to remove the solvent from the fluid preparations and convert them into masses of a greater degree of consistence, at the same time recovering the volatile solvents evaporated.

These inventions give a fair picture of the condition of the efforts to make a useful plastic from pyroxylin prior to the date of Hyatt's invention of celluloid which was patented July 12, 1870, and which in the clearest and most unequivocal language sets forth the nature of his invention. His claims are as follows :—

1. Grinding pyroxyline into a pulp, as and for the purpose described.

2. The use of finely comminuted camphor-gum mixed with pyroxyline pulp, and rendered a solvent thereof by the application of heat, substantially as described.

3. In conjunction with such use of camphor-gum, the employment of pressure, and continuing the same until the mold and contents are cooled, substantially as described.

Considering the claim that Daniel Spill was the inventor of celluloid, it is very significant that as late as the 11th of May, 1875, he took out a British patent 1739 of that year, for producing and applying Xyloidine. In this patent he makes no references to any material that could possibly be called celluloid. On the contrary, he recommends the following mixture as a suitable solvent for soluble guncotton or Xyloidine :—

250 parts by weight of alcohol.
150 parts by weight of ether.
10 parts by weight of nitrobenzole.
33 parts by weight camphor or camphor oil.
250 parts by weight hydrocarbons, from coal, shale or other bituminous substances boiling between 220 and 400° F.

Or he says the following solvent may be employed :—

400 parts alcohol.
200 parts hydrocarbons, before referred to, and
33 parts of camphor or of camphor oil.

Now this patent was taken out nearly five years after Hyatt's celluloid patent, and although Spill in this patent suggests adding a small quantity of camphor to large quantities of other solvents, volatile and non-volatile, he always mentions it as camphor or camphor oil, regarding them as equivalents. They certainly are equivalents for Spill's purposes to produce liquid solutions of pyroxylin, but camphor oil is not equivalent to camphor in Hyatt's process for making celluloid and it would be absolutely impossible to make celluloid by any process suggested in any one of these patents of Spill or Parkes, or any other inventor prior to Hyatt, and this is what the federal judges decided when the matter was tried out in court.

Meeting held at Chemists' Building, on Friday, April 24th, 1914.

MR. G. W. THOMPSON IN THE CHAIR.

WHO INVENTED CELLULOID?

BY ROBERT C. SCHÜPPHAUS, PH.D.

Being the author of the article on celluloid in the new edition of Thorpe's Dictionary of Applied Chemistry, from which Prof. Chandler* submits a mangled quotation with his emphatic disapproval, and looking back on thirty years' experience in the celluloid industry, I feel constrained to reply to the statements of the Professor.

It is necessary first to repeat that part of the history of the nitrocellulose industry which bears on the pyroxylin-camphor compound best known as celluloid. I concede at the outset that the word "celluloid," the registered trade-mark, was coined by one of the Hyatt brothers and that several books on the industry, all of them written by outsiders, ascribe the invention to Hyatt or the Hyatt brothers. Even Beilstein's great handbook falls into this error.

The first mention of camphor in conjunction with pyroxylin is contained in the British patent 1638 of July 26th, 1854, granted to James A. Cutting, of Boston, U.S.A., for photographic pictures. Cutting dissolved 32 grains of camphor in a pint of collodion, already containing 80 grains of potassium iodide, and claims by this addition to increase the vigour and distinctiveness of delineation of the positive picture and particularly the half tints, also the beauty of the picture, by giving a fineness of deposit not heretofore attained by any other means. The very nature of his solvent prevented him from observing any solvent action on the pyroxylin due to the presence of camphor, and nobody will be rash enough to assert that this disclosure of Cutting constitutes the invention of the pyroxylin-camphor compound.

The next mention of camphor is in British patent "Manufacture of Compounds of Pyroxylin" No. 1313, of May 11th, 1865, of Alexander Parkes, Birmingham, the one which is relied on to try to rob Spill of the credit due to him. Parkes mentions in this specification four solvents of low volatility, aniline, nitrobenzol, glacial acetic acid, and camphor, the latter only casually. The three former are specifically enumerated in his claim, but camphor is omitted, a point of significance to any one familiar with patent matters, especially in view of the fact that Parkes and Spill were associates. There is not a word in either this or any other of Parkes' patents that directs the joint use of absolute alcohol and camphor, as has been deduced by some from the famous decision (rendered August 21st, 1884) which held Spill's U.S. patent of November 30th, 1869, invalid. In patent 1313, Parkes recommends, as he does elsewhere, absolute wood alcohol or what he conceived to be such; and in his British patent No. 2675 of October 28th, 1864, "Preparing Compounds of Guncotton and other Substances," he states that alcohol, treated in an analogous manner, may be substituted for wood alcohol. Now both these alcohols gelatinise pyroxylin, so the dissolving power of camphor was not disclosed. Spill, who was a keen observer, noted that it was possible to use moist pyroxylin, as may be gathered from several of his patents, and drew the conclusion that in certain combinations the employment of anhydrous alcohols was not essential. In his British patent 2666 of September 21st, 1867, "Treating Xyloidine," he gives us the important solvent commercial grain alcohol mixed with benzol. Two years later, in British patent 3102 of October 26th, 1869, and U.S. patent 97,454 of November 30th, 1869, he published his famous formula of a solution of camphor in commercial grain alcohol, and this formula and this disclosure are and have been the foundation of the celluloid industry. Spill's process of gelatinising pyroxylins by means of this solvent and masticating the pasty mass between rolls is and has been the process followed by celluloid manufacturers all over the world, Hyatt and his backers included, and not the visionary, inoperative process of U.S. patent 105,338 of July 12th, 1870, granted to John W. Hyatt, jun., and Isaiah S. Hyatt. The patent covering this alleged invention was several times re-issued, exalted to the state of a fetish, and made an instrument of the most oppressive patent litigation. Hyatt disclaims the use of alcohol, but in practice cannot do without it. What his actual knowledge was, is best evidenced by this quotation from the text of U.S. patent 105,338: "The product is a solid about the consistency of sole leather, which subsequently becomes as hard as horn or bone by the evaporation of the camphor. Before the camphor is evaporated the material is easily softened by heat, and may be moulded into any desirable form, which neither changes nor appreciably shrinks in hardening. We are aware that camphor made into a solution with alcohol or other solvents of camphor has been used in a liquid state as a solvent of xyloidine. Such use of camphor as a solvent of pyroxylin we disclaim."

In passing, I may remark that the step of the first claim "Grinding pyroxylin into a pulp" was published in British patent 2249 of September 15th, 1860, granted to Stephen Barnwell and Alexander Rollason.

That Hyatt experienced great difficulty in circumventing Spill's patents and in fact did not succeed, does not constitute him the inventor of the pyroxylin-camphor compound which Spill first made, and which is made to-day by Spill's original method.

The decision that the step taken by Spill was too short to entitle him to a patent may have appeared very obvious in 1884, especially to his rivals, but I am of the opinion that it was a tremendous leap forward in 1869. But whichever way one may view this decision, it does not establish that Hyatt was the inventor of celluloid, the material, not the trade-mark, nor that Hyatt's process is the one used in the industry. Rather the reverse; it says that anybody may use Spill's process, Hyatt's backers, the defendants in this suit, included.

Considering the exceptional opportunities which Prof. Chandler has enjoyed to acquaint himself with the real processes and the history of the cellulose industry, nothing could be less defensible than the use he tries to make of Spill's British patent 1739, of May 11th, 1875. I append an extract from a circular of the Xylonite Company Limited, bearing date of March 31st, 1871, which shows better than anything else what had been accomplished at that early date.

"The Xylonite Company Limited."
"Manufactory: Hackney Wick, London, N.E."
"Mr. D. Spill, Manager."

"Xylonite: a substitute for Ivory, Bone, Horn, Tortoise-shell, Hard Woods, Vulcanite, Papier Maché, Marbles, Brass, and Veneers for Cabinet Work. It is also applied to Waterproofing Fabrics, Leather, Cloth, Book Binders' Cloth, Card Cloth, Writing Tablets, Bagatelle Balls and Pianoforte Keys, Gear and Friction Wheels, and Bearings for Machinery, Spinners' Bosses, Tubing; and as an Insulator and protector of Telegraph Wires.

"It may be embossed, turned, polished, and worked in the same manner as the substances above named; is not affected by chemicals or atmospheric changes, and is, therefore, valuable for shipment to hot climates.

"It is also applicable to Photographic purposes, viz., as windows for the Dark room, for which the material is chemically prepared so as to arrest the actinic rays of light. It can also be spread upon fabrics for the purpose of Field Tents, thus avoiding the use of coloured glass windows; and lastly, differently prepared, is a substitute for glass plates for Negatives, it having the advantages of being light, flexible, and durable, and perfectly structureless."

(Full instructions are given for surfacing and polishing sheet xylonite and for working and fixing handles.)

Tons of Spill's Xylonite were at this time imported into this country. Worden's description (Nitro-cellulose

---

* See preceding, page 677.

Industry, pp. 571, 572) of Spill's work is incomplete; his criticism of Parkes' processes (*ibid.*, p. 568, footnote) does not tally with the facts.

In regard to the dehydration of pyroxylin by means of alcohol, Mr. Hyatt labours under a misapprehension. This process is about as old as collodion itself, and was first patented by Cutting in 1854. It was first employed in an industrial way by J. R. France, the late President of the Arlington Company (died in 1895), and when his Company was sued for infringement of the Hyatt alcohol dehydration patent, it took only one hearing to cause a discontinuance of the suit.

The invention of celluloid has been discussed* before. I think I gave Mr. Hyatt due credit in the article which Prof. Chandler takes exception to, as I also did in 1895, when I said: "In the United States, J. A. McClelland and John H. Hyatt were at work to utilise the valuable properties of soluble pyroxylin. But ani nvention overshadowing all the others in importance was made by Daniel Spill in 1869, when he first produced a pyroxylin-camphor composition, plastic at about 75° C., by gelatanizing pyroxylin by means of a solution of camphor in commercial grain alcohol. As far as the chemical side is concerned, Daniel Spill must be hailed as the father of the celluloid industry, while to John W. Hyatt, at that time of Albany, N.Y., the greatest credit is due for devising suitable machinery for the intricate processes involved, for discerning the importance of pure materials, and for the perseverance which he exhibited under most adverse conditions."

It would have been much better to have the presentation of the Perkin medal to Mr Hyatt based on the things which he accomplished, of which there are a good many.

Discussion.

Prof. C. F. **Chandler** said that Dr. Schüpphaus had laid considerable stress on the fact that he had had thirty years' experience in the celluloid industry. His (the speaker's) familiarity with pyroxylin began about 1851, when as a boy fourteen years of age, he had made explosive guncotton, whilst in 1857 he had made his own soluble pyroxylin and collodion for photographic purposes, and, during recent years, had had occasion to look up the history of pyroxylin plastics as expert in the Kodak film case which had been recently decided. Since that time he had acted as expert in several investigations involving pyroxylin, explosives, varnishes, etc., and in June, 1881, had testified in the suit of Daniel Spill against the Celluloid Manufacturing Company. But in forming an opinion on the subject under discussion, he did not rely on his own experience. The issue was a matter which must be settled by facts. His quotation from Thorpe's dictionary was verbatim as follows: "The substance was first produced by Daniel Spill, of Hackney, England, and came into commerce under the name Xylonite." "Spill's method of converting the nitrocellulose has been followed for more than forty years." A verbatim quotation of two entire sentences, can hardly be said to be "mangled." In the first edition of Thorpe's Dictionary, the credit of first making celluloid is given to Hyatt. Further, Dr. Schüpphaus seemed to err in the use of the word celluloid, by making it include plastics containing not only pyroxylin and camphor but a variety of other substances such as animal and vegetable oils, gums, resins, etc., such as were made by Parkes prior to 1855 and later by his pupil, Spill, who became associated with Parkes in 1864 in the Parkesene Co. They did not call their product "Celluoid," and he had seen no evidence that led him to think hat they had ever made celluloid till after Hyatt made t, and a man who learned the process from Hyatt, later ntered the service of Spill.

The American conditions on which patents were granted were quite different from those that prevailed in England. n the United States, a patent could only be issued to the rst and original inventor. If a man who was not the riginal inventor secured a patent, it became null and void when it was shown that he was not the inventor. In England it was quite different. On March 23, 1876, Daniel Spill's Bill of Complaint against the Celluloid Manufacturing Co. was sworn to, and promptly filed in the Circuit Court of the United States. Spill came over himself, employed the best patent lawyers, testified himself, produced many other witnesses, took testimony in London by Commission, and spent eight and a half years in vainly trying to prove that the Celluloid Co. had infringed his patents. The weakness of his case was shown at the outset. With all his patents and those of Parkes, he was only able to charge two infringements: the use of camphor and alcohol solvent under patent 97,454 of 1869, and the bleaching of pyroxylin under patent 101,175 of 1870. The case was argued before Judge Blatchford, one of the most eminent United States judges, especially experienced in patent litigation. In his opinion given May 25, 1880, he decided that the defendant, the Celluloid Co., had failed to prove that Spill was not the first person to use camphor and alcohol to dissolve pyroxylin, or that he was not the first person to bleach pyroxylin. He declared both patents valid, and awarded to Spill recovery of profits and damages, to be ascertained by reference to a master, and a perpetual injunction. The injunction, however, had proved inoperative, for when the Celluloid Co. continued to manufacture and Spill's counsel made a motion to punish the Company for contempt, the Company showed that it had given up bleaching pyroxylin, and had substituted methyl alcohol for ethyl alcohol. The court had ruled that this was a valid defence and that the Company was not in contempt, so they continued to manufacture. In the meantime, the plaintiffs had proceeded to prove damages and profits and the defendant Company put in further evidence in defence. On February 25, 1884, the Master had filed his report, stating that Spill's lawyers had failed to furnish the necessary data to enable him to report any profits, or to fix any damages. Spill's lawyers claimed $276,667.66 on account of the alcohol camphor patent; $504,306.25 on the pyroxylin bleaching patent. The litigation was continued, more testimony was taken by both sides, and on August 21, 1884, Judge Blatchford reversed his original decision against the Celluloid Co. He decided on the testimony and documents presented that Spill's patent 97,454 was invalid as far as it claimed the use of camphor and alcohol as a solvent for pyroxylin, for the reason that this invention was made by Parkes. Further, he decided that Spill's patent 101,175 was invalid as far as it claimed bleaching pyroxylin, as that was not a patentable invention.

He did not think that either Dr. Schüpphaus or himself was competent to reverse the final decision of Hon. Judge Blatchford, reached after many years of litigation in which Spill had every opportunity to prove his case. He had certainly failed to prove that he invented celluloid, or that Hyatt's company had appropriated anything that he had invented.

Dr. R. C. **Schüpphaus** said in reply to Professor Chandler that he had been in six interference suits, and had been a witness and principal in more than a dozen patent suits. Of course, the fact that Spill was the inventor was shown by his United States patent. He naturally could not sue anybody in the United States on a British patent. He had explained somewhat in detail the decision of Judge Blachford in the suit of Spill against the Celluloid Company. It was not true, as he had said before, that in any of Parkes' patents could be read instructions to use absolute alcohol and camphor in conjunction. It could only be read into them. Spill, of course, did not claim the use of absolute alcohol and camphor, but he did claim the use of commercial grain alcohol and camphor, revealing for the first time the solvent properties of camphor, and that was a tremendous advance. It was very easy for a Judge in 1884 to give a decision that the step was too short to entitle Spill to a patent. But in those days it was a tremendous step, and it was an invention, and he thought that it might be upheld. Of course, the fact that Judge Blachford reversed himself was not a fit subject for discussion in a technical society.

Communication.

AN EFFICIENT STIRRING APPARATUS.

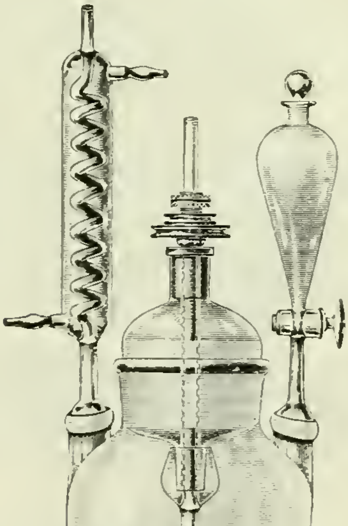
BY WILHELM GLUUD AND RICHARD KEMPF.

(*Contribution from the Davy-Faraday Laboratory, Royal Institution.*)

In chemical literature many suggestions are given for stirring apparatus which can be made by the worker himself from the simplest materials. Modern laboratory work, however, does not afford time for making apparatus: everything must be ready to hand and certain to work. Moreover, no ready-made apparatus would stir under varying conditions, such as under reflux, with exclusion of air, at high temperatures, etc. We had thus to make such an apparatus for ourselves.

The main idea of the construction is to meet as many needs as possible with *one* apparatus. We therefore made a constriction in the vessel, so that the part below the constriction held 500 c.c., in order to secure effective stirring of small quantities of liquid down to 150 c.c. The total capacity of the flask is about 1500 c.c., and this volume of liquid can be easily worked.

We had to avoid all rubber and cork stoppers, so as to be able to use the apparatus for nitration and similar processes, a thing which, so far as we know, is not done by any previous contrivance.* It was also necessary to make it possible to heat the whole arrangement in an oil- or water-bath, which, in spite of the strong glass used in its construction, can be done without any risk, owing to the high efficiency of present-day glass manufacture.



The apparatus also must easily be taken to pieces. This is done by loosening the screw above the driving-wheel. The inside screw is split, and, on screwing down the nut on to it, contact is made between the metal and the stirring-rod. The pear-shaped vessel fused to the shaft of the stirring rod serves the purpose—by trapping the lower end of the ground stopper in a fluid seal—of effectively preventing contact between the vapours in the main flask and the metal parts of the apparatus. In order to make all parts of the apparatus detachable, we had to arrange this pear-shaped vessel inside the main flask in which the reaction takes place.

The shape of the stirrer (which reaches nearer to the bottom than is shown in the diagram) adapts it for stirring up precipitates and making oils into emulsions.

The size of the hollow ground-stopper, which was necessitated by that of the stirrer, at first seemed somewhat dangerous, but nevertheless proved quite satisfactory. We chose this form of stirrer (which corresponds to the form used by Pieraerts (Chem. Zeit. 29, 671 (1905)), and which is like that used in the mash-tubs of breweries) because those with movable arms,* used, for instance, by E. Fischer (*loc. cit.*), often give trouble, especially when dealing with heavy liquids or thick precipitates.

Working at ordinary temperatures, it is sufficient to fill the pear-shaped vessel round the stirrer with water, paraffin oil, or mercury (in the latter case only half full). There is no danger of these liquids coming over the edge. At higher temperatures, some of the reaction mixture will distil over into the pear-shaped jacket. If interaction with the mercury should take place, as, for instance, in nitration, it is better to use instead a liquid heavier than water or dilute nitric acid, such as nitrobenzene or bromnaphthalene, etc., or, better still, to fill the jacket nearly full of water, then set up the whole apparatus, raise the stirrer a little, and, with a pipette, introduce a little paraffin oil into the space thus left between the metallic connection attached to the stirrer and the connection in the neck of the hollow stopper. The oil collects in the elongated joint of the ground-stopper, above the water, which may be contaminated with acid constituents, and prevents these from coming into contact with the metal. Our experience shows that even in rapid rotation the oil always stays in its place inside the elongated part of the stopper, but it is necessary to find out what quantity of paraffin is needed, as the different forces produce a stretching of the oil-layer, which may cause oil to enter the jacket itself.

In cases where contamination by acid vapours may be expected, the apparatus is very useful. When working in an atmosphere other than air, *e.g.* hydrogen, the dropping funnel can be replaced by a stopper fitted with inlet- an outlet-tubes, and liquids can be introduced through th condenser. For purposes of temperature measurement the apparatus is also fitted with an upright condenser int which a thermometer can be inserted.

The apparatus stands firm by reason of its own weight *one* clamp being sufficient, and even in rapid rotation th vibration is very slight. Steady rotation is best maintained by means of a small electro-motor, and the spee is regulated by tightening or loosening the belt connectin the motor to the stirrer.

Care should be taken to oil the joint of the stirrer an to grease the ground-stopper well. If grease must b avoided, graphite can be used instead. (R. Kemp J. Pr. Chem. (2), **78**, 207 (1908).)

After continued working at high temperature, it advisable to loosen the stopper while the apparatus is sti warm. We never experienced any difficulty in doing thi as the grinding is very carefully carried out. We ke the apparatus working for days at 100°, being placed a small porcelain support covered with sacking in a vess of boiling water.

Among the numerous experiments for which th apparatus was successfully used, only the almost qua titative oxidation of *o*-nitrotoluene to *o*-nitrobenzoic ac may be cited, which Ullmann (Ber. 36, 1797 (190 carried out in a specially constructed copper kettle.

The apparatus may be obtained from Gebr. Muenck Schumannstr. 2, Berlin, N.W.

Journal and Patent Literature.

Patent Specifications may be obtained by post by remitting as follows:—

English.—8*d.* each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1*s.* each, to the Secretary of the Society.

French.—1 fr. 05 c. each, as follows; Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue des Francs Bourgeois, Paris 3e.); Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—GENERAL PLANT; MACHINERY.

Paraffin motor; The ——. Times Eng. Suppl., June 26, 1914, **10**, 48.

Paraffin motors are suitable for powers of from 20 to 100 h.p. and have been constructed up to 180 h.p. The power obtained is about 10% less than with petrol, and the consumption is 0·7 to 0·8 pint of paraffin (sp. gr. 0·82) per b.h.p.-hour. The normal speed varies from 500 to 800 r.p.m. with the size of the motor, and the motor can be run down to one-fourth the normal speed. Paraffin carburettors, for running a petrol engine with paraffin, are not entirely satisfactory. In the paraffin motor, the vaporiser is usually heated by the exhaust gases, and the engine is started on petrol or the vaporiser is heated up by a blast lamp. A lower compression is used than in petrol motors.—A. T. L.

Mixing-machine; A new ——. L. Wickop. Z. angew. Chem., 1914, **27**, 318—320.

The stirring gear, working in a cylindrical vessel with a conical bottom, consists of a single paddle driven by a central vertical shaft. The paddle is shaped to act with centrifugal force in producing a funnel-like depression in the contents of the vessel. Adjustable "wave-breakers" are fixed at such a height that the outer and upper parts of the revolving liquid are dashed towards the centre of the funnel. Thorough mixing of the contents of the vessel is thus brought about very rapidly with low power consumption.—T. St.

Patents.

Mixing, washing, and screening materials; Apparatus for ——. F. G. S. Price, Glasgow. Eng. Pat. 12,191, May 26, 1913.

Two drums, mounted end to end, on the same horizontal axis, and containing respectively a right-hand and a left-hand approximately spiral passage, one of which is fitted with blades, communicate by a central opening containing a jet and a screw device for conveying material from one drum to the other. Peripheral ports receive and eject the material when the drums are rotated. The apparatus may be made wholly or partly of perforated material.
—O. E. M.

Boilers or evaporators. C. B. Catt, Harrogate, Yorks. Eng. Pats. 13,188 and 18,597, June 6 and Aug. 15, 1913.

The boiler is provided with vertical heating tubes into which gaseous or liquid fuel and air are passed; the fuel is burnt after impinging on fire-resisting granular material. The tubes are arranged in a circle around the axis of the boiler where the liquid to be heated is admitted. The air and fuel pipes leading to the tubes are similarly arranged in concentric circles and are connected with superposed air and fuel supply chambers. The supply pipes to these chambers are steam-jacketed.—A. T. L.

Evaporation and cooling of solutions or emulsions; Apparatus for the ——. W. G. Schröder. Ger. Pat. 273,547, Dec. 5, 1912.

The inner surface of a rotating jacketed drum serves as the heating or cooling surface. The drum is open at one end, but has a flange projecting inwards to retain the material. The solids which separate are removed from the surface of the drum by an adjustable scraper and fall into a trough whence they are removed by a screw conveyor driven by gearing from a spindle fixed to the closed end of the drum.—A. S.

Separators for treating inflammable or explosive materials; Electrostatic ——. J. Kraus, Braunschweig, Germany. Eng. Pat. 26,802, Nov. 21, 1913. Under Int. Conv., Oct. 27, 1913.

The electrically attracted particles are carried away by a movable dielectric arranged between the material to be treated and the attracting surfaces, the latter being formed of a substance which is a partial conductor, such as wood, marble, or the like, or of a non-conductor, such as glass, parchment, or the like.—B. N.

Centrifugal process of separation. J. Resines, Madrid. U.S. Pat. 1,097,561, May 19, 1914; date of appl., May 10, 1911.

A centrifugal separator comprises a cylindrical vessel rotating upon a vertical axis and having a number of horizontal ring-shaped baffles arranged in proximity to the cylindrical surface, so that the liquid passing through the separator is caused to flow alternately with and against the direction of the centrifugal force. The inner surface of the liquid in the separator is in contact with the atmosphere.—H. H.

Distillation apparatus. E. Hart, Easton, Pa., Assignor to General Chemical Co., New York. U.S. Pat. 1,096,838, May 19, 1914; date of appl., March 27, 1911.

At the top of the still is a horizontal tube from which a number of vertical tubes, closed at the lower end, project downwards into the still. The liquid (acid) to be distilled is run into the lower ends of the vertical tubes through thistle funnels, the heads of which are contained within a supply trough arranged above the apparatus.—H. H.

Crystallisation of salts and the like from solutions by cooling; Process for the ——. E. Fromme. Ger. Pat. 272,983, July 13, 1912.

The solution is forced through a cooling apparatus, under pressure, and with considerable velocity, whereby the crystals are prevented from adhering to the walls.—A. S.

Filtering apparatus. A. Hölken. Ger. Pat. 273,072, April 9, 1913.

The apparatus consists of two drums rotating in opposite directions, each composed of compartments, filled with sand and covered with filtering material. The material to be filtered is fed into the space between the drums and is carried forward and compressed between them. Means are provided whereby the compartments of the drum, as they become covered on their outer surface with the material, are put into communication with a suction device, in order to augment the capillary action of the sand and rapidly remove the liquid from the interstices thereof.—A. S.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Resins in Paleozoic plants and in coals of high rank. D. White. U.S. Geol. Survey, Professional Paper 85 E. pp. 65—83, plates ix—xiv.

The supposed absence of resins from the coals of higher rank has led to the view that the coal-forming floras of the Carboniferous period, to which most bituminous and higher-rank coals belong, were destitute of resin-bearing plants, and that these coals have not at any time existed as peats. From a study of petrified fragments of Carboniferous plants, and from observations of Paleozoic coals ("stone-coals"), the author concludes that some of the Carboniferous coal-forming vegetation contained secretions of a resinous nature which became concentrated in the coals owing to dehydration and the more rapid decay of the other plant tissues. Lump or exudate resins as well as canal secretions were found in Paleozoic coals of low bituminous rank. The failure to detect their presence in coals of higher rank is considered to be due to the changes which the resins undergo during the transformation of the coal. These changes, as shown in coals of the Cretaceous and Tertiary periods (usually lignites or brown coals), are a darkening of the colour to a smoky brown, followed by blackening, cracking and shrinking of the lumps, which are later reduced to dark brownish-black spongy or granular residues and finally to a thin, fine, powdery black scale. The reduction of the resins coincides with rapid de-oxygenation of the coal, and occurs when the proportion of fixed carbon in the coal substance is 60—65%. The qualities essential to the production of high-grade coke are developed at the same time.—A. T. L.

Refractory materials [for gas retorts]. Report of Refractory Materials Committee of the Institution of Gas Engineers. F. J. Bywater. J. Gas Lighting, 1914, **126**, 899—901.

Silica retorts.—These have recently been used in America with satisfactory results. The retorts were made from crushed ganister quartz (95% SiO_2), with 2% milk of lime as binding medium. They were of D-section, and were built up from bricks and tiles. The expansion on heating was 1/8 to 3/16 in. per foot, and was allowed for by making the joints either with thick paper or straw-board, which burned away leaving a thin carbon joint, or with cement consisting of mild aluminous clay, which shrank when heated. The mouthpiece ends of the retorts were made of solid moulded fireclay so as not to crack when cooled by the opening of the lid. The retorts were used with various types of hydraulic discharging machines. In some cases less carbon was formed on the inside of the silica retorts and the surface became glazed, facilitating discharge by pushers. The life of the retorts was 3½ to 4 years. The thermal conductivity was greater than with clay retorts, the fuel consumption was less, and the output greater owing to the shorter period required for burning off the charge.

Testing refractory materials under load.—The melting point of various clays used in the manufacture of firebrick and retort material was found to be 200°—320° C. lower when the clay was under pressures of 54 to 112 lb. per sq. in.—A. T. L.

Coke-ovens; Temperature distribution in ——. O. Simmersbach. Stahl u. Eisen, 1914, **34**, 954—958.

The temperatures in a Koppers oven were recorded every 12 minutes by pyrometers placed at three points along the axis of the oven, 1 metre above the sole, and also at three corresponding points in the free space above the coal. The period of coking was 29 hours. The temperature increased most rapidly, and was finally highest at the narrower charging end. The temperatures in the gas space above the coke did not change in the same way as the temperatures within the mass of coke at the corresponding points, but depended on the position of the gas-outlet. Samples of gas were taken every two hours. The proportion of carbon dioxide decreased from 3·3 to 1% in 19 hours and then became nearly constant; benzene decreased from 1·8% to zero in 17 hours; ethylene fell from 4 to 0·3 and methane from 36·65 to 4·7% during the whole period, whilst carbon monoxide increased from 0·9 to 5·8 and hydrogen from 42·5 to 70%. The heating value decreased from 5402 to 2419 cals. per cb. m.—A. T. L.

Surface combustion; Flameless incandescent ——. H. H. Gray. J. Gas Lighting, 1914, **126**, 786—789.

The author criticises the view that surface combustion consists in a catalytic action of the incandescent surface and that the combustion takes place in molecular layers in contact with the surface. The size of a gas flame is reduced by increased aeration, and depends upon the time required for the gas and the oxygen to mix and burn. The absence of flame when a mixture of gas and air is brought into contact with an incandescent surface is therefore to be expected. The process occurring in the tube of a Bonecourt boiler is considered to be a modified detonation in which the propagation of the combustion through the gaseous mixture is effected by the incandescent solid instead of by the adiabatic compression of a detonation wave. The setting up of a detonation wave is prevented by the rapid flow of gases in the opposite direction and by the baffling effect of the solid material.—A. T. L.

Carburetting water-gas; Thermal reactions in ——. M. C. Whitaker and W. F. Rittman. J. Ind. Eng. Chem., 1914, **6**, 383—392, 472—479.

The first portion of the paper comprises a comprehensive theoretical study of the manufacture of carburetted water-gas from the standpoint of mass action and thermodynamics, the effects of temperature, pressure and concentration on the equilibria being considered. (See also Rittman, this J., 1914, 626.) It is deduced from the theoretical considerations that to obtain a maximum yield of gaseous illuminants by "cracking" petroleum, the process should be carried out at low pressure (to increase the yield of gaseous products) and in an atmosphere of end products, such as hydrogen and methane (to prevent the decomposition of hydrocarbons otherwise necessary to furnish the proportions of such end products required to maintain equilibrium). The equilibrium conditions in the manufacture of "blue" water-gas have already been thoroughly investigated (Hahn, this J., 1903, 1038; Jüptner, 1904, 977; Allcut, 1911, 606; Neumann, 1913, 352), and in the present investigation only the "cracking" of the oil was studied experimentally. The oil used (400 c.c. in each experiment) was "150° (F.) water white oil" of sp. gr. 0·7984 at 15° C., b.pt. 150°—290° C. The results of some of the tests approaching most nearly the desired object, *i.e.*, to increase the yield of illuminants by obtaining the largest yield of hydrocarbons and eliminating, as far as possible, carbon dioxide, water vapour, deposited carbon, and tar vapours, are given in the following table:—

Temp.	Pressure.	Gas.	Carbon.	"Tar."	Illuminants in gas.
C.	atmos.	litres.	grms.	c.c.	%
750	$\frac{1}{20}$ to $\frac{1}{30}$	146	1	153	56·1
850	do.	211	3	100	52·9
900	do.	234	3	60	52·1
950	do.	235	12	58	46·9

In further experiments in which the oil was cracked in an atmosphere of hydrogen, a considerable proportion of the added hydrogen was converted into hydrocarbons, the quantity and quality of the gas increased, and the quantities of tar and deposited carbon decreased. (See also Hempel, this J., 1910, 261.)—A. S.

[Coal-gas;] Purification of —— by heat. C. C. Carpenter. J. Gas Lighting, 1914, **126**, 928—938. (See also this J. 1913, 742.)

Plant for passing purified coal-gas over finely divided nickel at 430° C. so as to convert carbon bisulphide into hydrogen sulphide, which is then removed, has been installed capable of treating 15 million cb. ft. of gas per day. The plant consists of 5 units, each comprising a gas-producer and combustion chamber, two heating chambers containing vertical reaction tubes packed with the catalytic material, and two heat-interchangers for preheating the gas to 400° C. The weight of nickel used is 1321 lb., and the plant consumes 5½ tons of coke per day. The average quantity of sulphur in the gas was reduced from 35·07 to 7·82 grains per 100 cb. ft. or by 77·7%. The greatest reduction was from 63·78 to 10·34 (83·8%), and the least, from 19·21 to 5·34 (72·2%). The quality of the gas was as follows :—

	Before treatment.	After treatment.
Illuminating power (candles)	14·7	14·7
Calorific power (gross B.Th.U.)	590	594·4
Naphthalene (grains per 100 cb. ft.)	5·54	4·71
Hydrocyanic acid („ „)	22·19	18·75
Analysis (% by vol.) :—		
Carbon dioxide	1·44	1·45
Hydrocarbons	3·55	3·63
Oxygen	0·33	0·06
Carbon monoxide	8·16	8·03
Methane	26·85	27·26
Hydrogen	54·19	54·25
Nitrogen	5·48	5·32

One of the retort houses was worked at low temperature so as to produce gas of average candle-power 20·54 ; after treatment the candle-power of this gas was 20·46. The capital cost of the plant was about £1500 per million cb. ft. per day and the working costs were 0·299d. per 1000 cb. ft., including repairs, maintenance, interest, and depreciation. Plant for treating 1½ million cb. ft. of gas per day has been worked for 2 years. The wasting of the reaction tubes is very slight and the efficiency of the catalyser is unimpaired.—A. T. L.

Lighting gas ; Removal of sulphur from ——. G. Anderson. J. Gasbeleucht., 1914, **57**, 547—552, 569—575.

Pure dry hydrogen sulphide was passed through a tube containing either (A) ferric oxide (96·4% Fe_2O_3), (B) ferric hydroxide (Fe_2O_3 66·5, H_2O 17·4, impurities 16·1%), or (C) precipitated ferric hydroxide. The atomic proportion of sulphur absorbed when the material was saturated, as shown by the presence of hydrogen sulphide in the issuing gas, was : (A) 0·48 and 1·06, (B) 0·85 and 0·97, and (C) 0·67 S for each atom of Fe. Further experiments showed an increased absorption of sulphur with increased subdivision of the oxide, and with decreased velocity of the current of gas. Dry ferric oxide was as active as the hydroxide, but the activity could be destroyed by heating. With moist hydrogen sulphide the atomic proportion of S to Fe in the saturated material was less than with the dry gas :—(A) dry gas 0·83, moist gas, 0·76 ; (B) dry gas, 0·97, moist gas, 0·75 ; and (C), dry gas, 0·67, moist gas, 0·63. With precipitated ferric hydroxide, the proportions were 0·55 with moist hydrogen sulphide containing ammonia, 0·59 with moist hydrogen sulphide free from ammonia, and 0·67 with dry hydrogen sulphide, and with more finely divided material, 1·29 with moist hydrogen sulphide containing ammonia, and 1·11 and 1·47 with dry hydrogen sulphide. With a dry mixture of hydrogen sulphide and ammonia, the proportions were 0·996 and 1·073, compared with 1·472 and 1·456 in similar experiments with pure dry hydrogen sulphide. The composition of the spent oxide was the same with pure and with ammoniacal hydrogen sulphide. From 15 to 38% of the sulphur could be extracted with carbon bisulphide and about 4% was present as iron disulphide. The atmospheric oxidation of the spent oxide at the ordinary temperature gave free sulphur, and only traces of ferrous sulphate. The iron disulphide was not oxidised. In experiments with precipitated ferric hydroxide and a purified lighting gas to which 0·3 to 1·85% by volume of hydrogen sulphide was added, the spent material contained a much lower atomic proportion of sulphur (0·56—0·19 S for each atom of Fe), the proportion being higher with moist than with dry gas. In gas works, the author has used oxides obtained as by-products in working up copper ores, and in making alum from bauxite. These materials when finely divided and used without sawdust will absorb 68—69% S. The oxide should contain not more than 25% of moisture. The volume of gas purified per metric ton of the fresh material varied from 188,900—141,730 cb. m., with velocities of the gas-current varying from 8 to 10 mm. per sec., and with a revivified material the volume varied from 163,000—93,270 cb. m. with velocities from 6·0—7·7 mm. per sec. The crude gas contained 0·7% (by vol.) H_2S. Tar, cyanogen and ammonia were first removed from the gas, and 2 to 4% of air added at the inlet to the oxide-purifiers. The proportions of free oxygen in the gas entering the first, second and third purifiers and in the gas leaving the third purifier were 0·7—0·5, 0·5—0·4, 0·35—0·25, and 0·3—0·2% respectively.

For the determination of sulphur in gas the author uses the Drehschmidt apparatus ; the rate of burning the gas should not exceed 15 litres per hour. Oxidation of the combustion products to sulphate is effected with hydrogen peroxide instead of bromine, and the sulphur is determined by titrating the free acid. A determination can be made with half the quantity of gas required when the sulphur is weighed as barium sulphate. Comparative results were :—by titration, (A) 41·22, (B) 53·89, (C) 49·01, (D) 48·24, and by gravimetric analysis (A) 41·69, (B) 53·38, (C) 50·8, (D) 47·87 grms. S per 100 cb. m. of gas.

In laboratory experiments, air containing carbon bisulphide was passed over hydrated iron oxide at various temperatures. The sulphur was partially removed, with formation of iron sulphide and carbon dioxide. At 90° C., the heat of the reaction caused ignition of the gas. Purified lighting gas containing 49—57 grms. S per 100 cb. m. was passed over hydrated iron oxide at temperatures from 32°—87° C. ; the proportion of sulphur removed varied from 7·6—46·0%, being greatest at 80° C. The proportion of sulphur removed was still greater at temperatures up to 250° C.—A. T. L.

Gasoline ; Suitability of natural gas for making ——. G. A. Burrell. Techn. Paper 17. Dept. of the Interior, Bureau of Mines, U.S.A. Sept., 1913, 17—23.

In the state of Oklahoma alone the recoverable gasoline escaping as gas is estimated at 10% of the crude oil obtained. In many of the plants the natural gas is drawn from 50 or more wells 4 miles away under a reduced pressure of 25 in. The gas is first compressed at 25 to 50 lb. per sq. in. and passed through cooling coils sprayed with water. A small amount of liquid is thus obtained, and the residual gas is compressed at 350 lb. per sq. in. and cooled as before. The yield is about 1½ to 4 galls. of liquid per 1000 cb. ft. of gas, and the products range from 0·676 to 0·582 sp. gr. The latter constitute the "wild" products and lose from 10 to 50% on exposure. The methods of testing the natural gas include determinations of the sp. gr. and solubility in "claroline" oil, kerosene, alcohol or olive oil, combustion analysis, and practical trials at the well-head with gasometer and compressor. Gases with density as low as 0·81 (air = 1) and as high as 1·64 have been used, while natural gas with an absorption coefficient of only 30 (in "claroline" oil) is being compressed. The absorption test is made by shaking 100 c.c. of the gas with "claroline" oil or with 50 c.c. of alcohol. Few plants deal with as little as 40,000 cb. ft. of gas daily, and the most successful use at least 125,000 cb. ft. Great variations in quantity and composition of the gas may be shown by adjoining wells. A plant costing $9000 to $10,000 (£1850 to £2055) will deal with 500,000 cb. ft. of gas per day, and can be worked by two men. (See also this J., 1912, 630 ; 1913, 999, 1096.)—C. A. M.

Petroleum from Bioritsu, Formosa ; A study of the crude ——. T. Katayama. J. Ind. Eng. Chem., 1914, **6**, 469—471.

The most important oil deposit in Formosa is at Shukkokosio, 7 miles south of Bioritsu. The crude oil is a clear, mobile, brownish liquid, which solidifies at 0° C. It has the sp. gr. 0·831 at 15° C. and yields the following fractions on distillation : below 100° C., 1·5% by vol. ; 100°—125°, 15·8 (sp. gr. 0·7770) ; 125°—150°, 21·8 (0·7980) ; 150°—

175°, 12·2 (0·8155); 175°—200°, 8·8 (0·8205); 200°—225°, 7·8 (0·8360); 225°—250°, 7·6 (0·8585); 250°—275°, 7·5 (0·8790); 275°—300° C., 4·3; residue, 13·2% by vol. (solid at ordinary temperature). The kerosene fraction (150°—275° C.) after being refined by the usual method could not be used as a lamp oil owing to its very smoky flame. The smoky constituents appear to be aromatic hydrocarbons; they are soluble in acetic anhydride, are readily nitrated, and have a higher sp. gr. than the non-smoky constituents. They can be removed by treating the oil with a sufficient quantity of concentrated sulphuric acid, especially on heating to 100° C. By treating the kerosene with 5% of sulphuric acid for 5 hours at 100° C. an oil giving a non-smoky flame was obtained, and the quality improved as the proportion of acid was increased.—A. S.

Paraffin wax; Separation of —— from petroleum oils by cold methods. M. A. Rakusin. Petroleum, 1914, **9**, 1374—1375.

By centrifuging petroleum oils at the ordinary temperature the proportion of paraffin wax, asphaltic substances, etc., is reduced, as is indicated by the lowering of the solidification pt. (*e.g.*, from 9° C. to 6° C.). This effect increases with the decrease in the temperature of centrifuging. Thus at 5° C. the solid. pt. of the oil was reduced from 9° C. to 1° C. Carbonaceous substances ("*kohligen Substanzen*") are also partially eliminated, as is shown by the increase (about 30%) in the "carbonisation constant" of the oil (see this J., 1909, 514). The sp. gr. of the oil is reduced (*e.g.*, from 0·8619 to 0·8549).—C. A. M.

Naphthenic acids; Experiments upon the deodorisation of ——. E. Schmitz. Les Matières Grasses, 1914, **7**, 4115—4117.

Hexa- and hepta-naphthenic acids, prepared synthetically, had an odour similar to that of the technical products, but by distillation at 250° C. (90 mm. pressure), the odour was considerably diminished though not eliminated. By treating the "petroleum acids" of the alkaline lyes from the refining of lamp oils with dilute sodium carbonate solution, "salting out" the naphthenic soaps, liberating the naphthenic acids, and repeating the process several times, the final product had only a very faint odour. The oxygenated compounds insoluble in sodium carbonate solution but soluble in potassium hydroxide solution were of a phenolic character, and had a dark colour, and an intense penetrating odour. They could be brought into solution in the naphthenic soap by adding a very small amount of sulphuric or hydrochloric acid. They gave an intense bluish-green coloration with copper salts, and to their presence is attributed the well-known reaction of naphthenic acid with copper salts. This reaction, however, is by no means characteristic, since copper oleate is also soluble in petroleum spirit. It is suggested that the "oil," which forms a layer beneath naphthenic soaps when "salted out," should be used as a basis of green lacquers, for wood, etc. It forms about 1% of the crude "petroleum acids." Hydrogenation in presence of a catalytic agent did not affect the odour or properties of crude naphthenic acids. Treatment with ozonised air for 1½ to 2 hours at 14·3° to 16·5° C. caused slight reduction in the odour and colour, and increased the sp. gr. (*e.g.*, from 0·9622 to 0·9665). At 50° C. ozone caused slight bleaching, followed by the formation of a yellow precipitate, whilst at 100° C. it produced polymerisation changing the colour of the acids to wine red, but not improving the odour. Treatment with ozone for a short time at a low temperature would be useful, provided that the naphthenic acids had first been freed from the malodorous phenolic substances by treatment with sodium carbonate or preliminary "salting out" as described.—C. A. M.

PATENTS.

[Peat] Fuel; Production of ——. T. O. Franke, London. Eng. Pat. 12,233, May 26, 1913. Under Int. Conv., Nov. 9, 1912.

Combustible substances, such as coke dust, which are mixed with peat to facilitate the escape of water under the press, are rendered impervious by impregnating them with solid or liquid organic substances.—O. E. M.

Coke-ovens. N. Schuster, London. Eng. Pat. 29,494, Dec. 22, 1913.

To avoid overheating the gas with which regenerative coke-ovens are fired, cold air is drawn through channels, parallel and adjacent to the gas passages, by connecting the channels with the uptake. The gas nozzles deliver into a chamber, with inclined walls, below the heating flues, and are thus protected from falling débris. The gas pressure is maintained at the inner ends of the gas passages by gradually diminishing their cross-sectional area and providing an intermediate auxiliary gas passage. —O. E. M.

Coke-oven. F. W. Sperr, jun., Chicago, Ill. U.S. Pat. 1,097,196, May 19, 1914; date of Appl., Jan. 31, 1914.

In a regenerative coke-oven, the fuel passages underneath the heating flues are provided with valves to admit air for consuming carbon deposits therein, the arrangement being such that half the passages can be so treated while the other half are in use for heating the oven. —H. H.

Gas; Charging or discharging retorts used in the manufacture of ——. Drakes Ltd. and A. Dobson, Halifax. Eng. Pat. 4105, Feb. 18, 1913.

The vertical or inclined retort is closed below by two concentric semi-cylindrical drums, one fitting just inside the other, and both having toothed cutting edges. The drums are rotated in opposite directions. When the drums are in one position the coke in the lower portion of the retort descends into the open side of the inner drum; the cutting edges of the drums then approach each other and detach the coke in the drum from that in the retort. —J. L. F.

Gas retorts; Drawing and charging ——. H. Bird and G. Hayter, Hayes. Eng. Pat. 12,976, June 4, 1913.

The coal is held in position in the retort by means of a suitable frame, carrying hinged plates, during the withdrawal of the scoop, the frame being subsequently withdrawn by independent mechanism. The coke is removed by telescopic channel irons severally fitted with rake and plate, which ride up on their hinges upon insertion into the retort, but engage with the coke upon withdrawal. The plate travels twice as fast as the rake, both being arranged to complete their working-stroke simultaneously. —J. L. F.

Vertical retorts for carbonising coal; Heating of ——. A. M. Duckham, Ashtead. Eng. Pat. 12,338, May 27, 1913.

The air or air and gas are preheated by means of the heat of the coke, by passing them through flues disposed around the lower part of the retort. In contact with these flues is a second set of flues through which the waste gases from the heating flues are passed in order further to augment the temperature of the air or gas.—J. L. F.

Gas and coke; Process for the immediate fractional recovery of the bye-products obtained in the production of illuminating town ——. J. Fischer, Vienna. Eng. Pat. 21,290, Sept. 20, 1913.

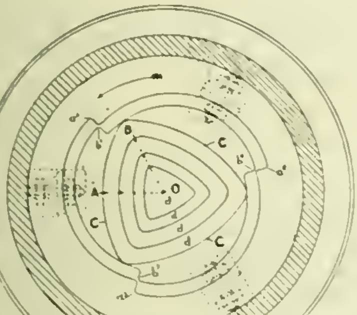
The gases issuing from the retorts are passed in a thin stream through a series of vertical hollow plate condenser maintained at various temperatures by the circulation of air and water respectively. The air-cooled condensers are cooled by a single current of the cooling medium, which is reduced in temperature where necessary in passing from one condenser to another by circulation through long pipes exposed to the air.—H. H.

Water-gas ; Apparatus for producing ——. A. Choury, Nanterre, France. Eng. Pat. 19,363, Aug. 27, 1913.

In a generator in which the air-blast passes upwards and the steam-blast downwards through the fuel, the air and steam are preheated by passing through coiled pipes arranged in an annular chamber between the generator walls and an outer casing.—A. T. L.

Gas producers. A. Sahlin, Brussels. Eng. Pat. 27,888, Dec. 4, 1913.

The blast is distributed by a central stepped conical grate (shown in plan in the figure) carried by a revolving water-sealed ash-pan and having annular orifices between the successive steps, *d*. The several steps, *d*, of the grate are triangular pyramidal frustums with convex sides, so proportioned that the smallest radius, OA, of the base of each frustum is equal to the extreme radius, OB, of the base of the next frustum above it, whereby the blast is distributed as an even sheet and the fuel receives a gentle undulatory and gyratory motion. The ash-pan also carries a cam-shaped scraper formed in two vertical steps, a^1, a^2, a^3, and b^1, b^2, b^3, above which is a vertical wall, C, of the same shape as the lowest section of the conical grate, which ensures the passage of the ashes into the pockets formed by the cam-shaped scrapers.—A. T. L.



Gas producer. H. Poetter, Dusseldorf, Germany. U.S. Pat. 1,097,141, May 19, 1914 ; date of Appl., Nov. 28, 1913.

A portion of the cylindrical wall of a gas producer is rotatable and carries a hollow stirrer which projects laterally into the distillation zone of the producer. As the stirrer rotates, it is simultaneously oscillated in an upward and downward direction by an eccentric. The stirrer is cooled by circulation of air therein.—H. H.

Gas ; Manufacture of ——. H. W. Benner, Bethlehem, Pa., Assignor to International Gas Development Co., New York. U.S. Pat. 1,097,513, May 19, 1914 ; date of Appl., Feb. 25, 1914.

The coal is charged into vertical retorts which have previously been heated to a temperature sufficiently high to initiate the distillation, and water-gas is then passed through the charge from below in sufficient quantity to prevent the deposition of carbon from the distilling gases upon the walls of the retort. The water-gas is preferably produced by forcing steam through a layer of incandescent coke introduced at the bottom of the retorts before they are charged with coal.—H. H.

Gas liquor ; Process for the treatment of ——. Berlin-Anhaltische Maschinenbau-A.-G. Ger. Pats. 269,658, May 10, 1913, and 272,985, Oct. 22, 1913.

(1). The gas liquor is first introduced into a vessel heated by the waste heat of the retort-furnace, whereby a portion of the volatile ammonia is expelled, and the remainder is then driven off by heating the liquor more strongly in a second vessel. The hot liquor from this second vessel serves to heat the acid bath in which the volatile ammonia is absorbed and then passes to the water-seal of the retort-furnace to be evaporated beneath the grate. (2) The evaporating vessels in which the liquor is heated strongly to drive off the last portions of the volatile ammonia are disposed in the masonry at the top of the retort-furnace. —A. S.

Ignition of gases ; Apparatus for determining the speed of —— by measuring the inner cone of the flame. M. Hofsäss. Ger. Pat. 272,705, Aug. 28, 1913.

The gas is burnt in a Bunsen burner connected at its lower end with a pressure-gauge and a regulator for ensuring a constant pressure and at its upper end with a device whereby the height of the inner cone of the flame can be measured or recorded photographically. The supplies of gas and of air are so regulated that the inner flame has approximately the shape of a right cone, the surface of which is directly proportional to its height. The speed of ignition of the gas is equal to the quotient of the velocity at which the mixture of gas and primary air is supplied to the burner and the surface of the inner cone of the flame. For example, under similar conditions the surface of the inner cone of a carbon monoxide flame is about six times that of the inner cone of a hydrogen flame, the speed of ignition of hydrogen being six times greater than that of carbon monoxide.—A. S.

Oils ; Treatment of —— for cracking, particularly for the manufacture of liquid combustibles. C. E. C. Luck, Dartford, Kent. Eng. Pat. 12,059, May 23, 1913.

Liquid fuel for internal-combustion engines is made by fractionally distilling a mixture of petroleum (sp. gr. not exceeding 0·805), benzene, a gum resin or a resin and picric acid. For example, 12 galls. of 90% benzene are mixed with 84 galls. of petroleum and a solution of 5 lb. of rosin in 1½ galls. of 90% benzene. A solution of 5 lb. of picric acid in 2½ galls. of 90% benzene is stirred in and the mixture distilled. The distillate passing over between 125° and 205° C., forming about 75—80% of the original volume, is collected, and any further distillate is added to the original mixture.—A. T. L.

Combustible mixtures for internal-combustion engines. G. E. Heyl, London. Eng. Pat. 18,417, Aug. 13, 1913.

Rich gases such as acetylene, coal gas, etc., are diluted with air sufficiently to preclude ignition, and free hydrogen is added in sufficient quantity to propagate ignition through the mixture in the manner described in Eng. Pat. 4570 of 1913 (this J., 1913, 903).—A. T. L.

Process for obtaining sulphur by the interaction of sulphur dioxide and hydrogen sulphide. Ger. Pat. 272,474. *See* VII.

Gas analysis apparatus. Eng. Pat. 17,676. *See* XXIII.

IIb.—DESTRUCTIVE DISTILLATION ; HEATING ; LIGHTING.

Carbonisation ; Thermal phenomena in ——. H. Hollings and J. W. Cobb. J. Gas Lighting, 1914, **126**, 917—924.

Bituminous coals, anthracites, cannel coal, cellulose and dehydrated cellulose were heated under the same conditions as a sample of coke, and the temperature compared with that of the coke in order to determine when heat was being absorbed or evolved by the decomposition of the coal or cellulose. In all cases, distillation commenced at 250° C., and up to 1100° C. various exothermic and endothermic stages of the distillation were observed. The total quantity of heat evolved or absorbed on balance was very small. With coal there was no sudden decomposition at a definite temperature such as occurs with cellulose. In a typical experiment with bituminous coal containing 40·2% of volatile matter, endothermic reactions predominated up to 410° C., exothermic from 410° to 470° C., and endothermic from 470° to 610° C. The exothermic stage above 610° C. was always very marked, and was interrupted between 750° and 800° C. Exothermic reactions probably continue to a higher temperature. The evolution of heat above 610° C. was probably due to reactions in which methane was produced, these reactions being succeeded at 750° C. by others in which large quantities of hydrogen were formed.—A. T. L.

Coal-gas and petrol [air-] gas [for lighting] : a comparison. E. Scott-Snell. J. Gas Lighting, 1914, **126**, 708—710. (See also this J., 1913, 128.)

For equal amounts of heat of combustion, petrol air-gas with petrol at 1s. 10d. per gall. costs four times as much as coal-gas at 2s. 2d. per 1000 cb. ft. When used in incandescence burners for lighting, taking into account the lower density and the smaller proportion of added air in the case of petrol air-gas the author calculates that coal gas must be supplied to the burner-nozzle at a pressure 10·3 times as great as for petrol air-gas in order to form a completely combustible mixture moving with the same velocity. Hence low-pressure petrol air-gas, at say 2 ins. water column, produces a lighting effect similar to that of high-pressure coal-gas at about 20 ins. water column. Light petrol has been found to give 9350 candle-power-hours per gall., and assuming a lower efficiency than this, the cost is calculated at 2·5d. per 1000 candle-power-hours, with petrol at 1s. 10d. per gall. On this basis, petrol-air gas cannot compete with coal-gas in towns ; it is, however, much cheaper than acetylene lighting, estimated to cost 6·7d. for 1000 candle-power-hours.—A. T. L.

Electrodes; Light from unconsumed ——. A. Vosmaer. Met. and Chem. Eng., 1914, **12**, 377—379.

If the discharge from a Ruhmkorff induction coil equipped with a modern Wagner hammer be made to pass between 2 nickel wires about 2 mm. apart, the ends will burn and form globules. If now the distance is increased to 3—4 mm., the wires will go on glowing without further adjustment. No oxidation or vaporisation takes place, as the distance between the wires remains the same, and spectroscopic examination shows a continuous spectrum without lines. Platinum wires melt rapidly under the same conditions. If a copper wire is substituted for one of the nickel wires, the nickel electrode glows while the copper electrode remains dark.—W. R. S.

Patents.

Distillation of wood, soft coal, lignite, peat and shale, and utilisation of the products of the distillation for creosoting timber and for other purposes. D. de Nagy, London. Eng. Pat. 12,427, May 28, 1913.

The wood or other material is stacked upon a circular platform beneath which are a number of chambers, separated by radial walls, communicating with a central chimney. The wood, etc., is covered in with cardboard saturated with soluble glass, and with an outer layer of earth, in which suitable holes are made to maintain combustion. The mass is ignited in the interior, and the distillation products pass downwards through gratings into the chambers beneath the platform, and thence to the chimney, the draught being regulated by a damper. The condensed portions of the distillate are run off from the chambers. Two or four of the chambers are fitted with air-tight iron linings and connected with compressors so that wood can be creosoted in them with the fresh products of distillation.—A. T. L.

Combustion of combustible mixtures. Furnaces or other heating apparatus. C. D. McCourt and Bonecourt Surface Combustion Limited, London. Eng. Pats. 11,956 and 11,957, May 22, 1913.

The apparatus described in Eng. Pats. 25,808 and 29,430 of 1909 (this J., 1910, 1448) is provided with a chamber in which the sprayed liquid fuel, or gas, is mixed with air and partially burnt, before reaching the region of surface combustion.—O. E. M.

Heating or cooling fluids ; Apparatus for ——. H. B. Watson and T. C. Billetop, Newcastle-on-Tyne. Eng. Pat. 19,970, Sept. 4, 1913.

The apparatus of surface-condenser type described in Eng. Pat. 7023 of 1911 is made more efficient by providing diaphragms to promote the circulation of the cooling water round the tubes and of the liquid to be cooled within them, by making the ends of the tubes bell-mouthed, and by leading the hot liquid in at the top and the cooled liquid out at the bottom, to assist in maintaining its flow. —O. E. M.

Incandescent body for electric glow lamps, and process for the manufacture of such bodies. A. Just, Budapest, Hungary. Eng. Pat. 8956, April 16, 1913. Under Int. Conv., April 18, 1912.

Filaments are made from a micro-crystalline solid solution in tungsten of 0·1 to 3·0% Cr, V, Mo, Th, Ti, Mn, Bi, U or Zr. Such solutions are made by melting the metals together *in vacuo* in an electric furnace with tungsten electrodes, or by compressing the powdered metals into the form of a rod and passing an electric current through the rod. The hot metal is chilled by immersion in oil or water, and finally tempered by heating to 1200° C. and allowing to cool slowly, rolled or hammered, and drawn into the required form.—A. T. L.

Arc-light carbons. H. Ayrton, London. Eng. Pats 22,319, Oct. 3, 1913, and 7792, March 27, 1914.

The negative carbon is coated with a thin film of coppe or other material less combustible than carbon. Th copper is volatilised to a distance from the arc dependin on the thickness of the coating, and the thickness i therefore determined so as to give a carbon tip tapere to such a length as ensures a steady arc, and a rate o burning equal to that of the positive carbon. The negativ carbon is made hollow but closed at the outer end, th hole being of such size that the arc completely surround it. There may be a central pencil of carbon within th hole. For an open direct-current arc using a current o 85 amperes with a cored positive carbon, the negativ carbon is made 12 mm. diam. with a hole 2 mm. diam and a coating 0·04 mm. in thickness. The cross-sectio of the negative carbon is less than half that of the ordinar carbon, and the arc throws less shadow.—A. T. L.

White light resembling normal daylight ; Production of —— P. Grosheintz, Basel, Switzerland. Eng. Pat. 26,11 Nov. 14, 1913. Under Int. Conv., Nov. 16, 1912.

The light is produced by surrounding an incandescen electric lamp or other source of light radiating an exce of reddish-yellow rays with an envelope consisting sole of cobalt blue glass of the requisite tint and intensity. —H. H.

III.—TAR AND TAR PRODUCTS.

Trinitrotoluene ; Waste product from the manufacture ——. E. Molinari and M. Giua. Z. ges. Schiess- u Sprengstoffw., 1914, **9**, 239.

The heavy duty on spirit in Italy renders it impossil to make trinitrotoluene from the residues obtained in t manufacture of dinitrotoluene for dyes, as is done Germany. A dinitrotoluene must be prepared of sufficie purity to yield on nitration a trinitrotoluene melting at 80° C. without purification. The orange-red oily liquid removed by the centrifugal from crude dinitrotoluene intended for further nitration was investigated. A series of fractional distillations and crystallisations showed it to contain *m*- and *p*-nitrotoluene, 1.2.4-dinitrotoluene, constituting 20% of the oil, 1.2.5-, 1.2.6-, and 1.3.4-dinitrotoluene, 1.2.3.5- or 1.2.3.6-trinitrotoluene (a new isomeride), 1.2.4.6-trinitrotoluene and a crystalline substance probably consisting of nitroxylenes.—O. E. M.

Nitro-compounds; Investigations on ——. I. Mutual solubility of some nitrotoluenes in the solid state. M. Giua. Ber., 1914, **47**, 1718—1723.

THE fluidity of the oil obtained as a by-product in the preparation of 1.2.4-dinitrotoluene is evidently due to the mutual solubilities of the isomerides present. Four systems were studied: *p*-nitrotoluene and 1.2.4-dinitrotoluene, 1.2.6- and 1.2.4-dinitrotoluene, 1.2.4-dinitrotoluene and 1.2.4.6-trinitrotoluene. In all cases the melting-point curves had a horizontal portion indicating the formation of a compound, which contained in general 3 mols. of the lower to 2 of the higher nitro-compound, and was completely dissociated in the liquid state. These compounds form so slowly that the metastable region could be investigated, so that in all cases but the last the existence of a metastable eutectic point could be demonstrated.—O. E. M.

PATENT.

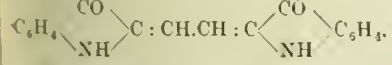
Pitch filter. A. Michel, jun. Ger. Pat. 273,664, Sept. 25, 1913.

THE apparatus comprises a steam-jacketed vessel divided into three superposed compartments. The crude pitch is melted in the top compartment, and flows through a sieve into the middle compartment, in which is the filter proper, consisting of three vertical concentric gauze cylinders, the innermost one having the finest mesh. From the interior of the filter, the pitch passes through a valve, operated from outside, into the bottom compartment, from which it is drawn off.—A. S.

IV.—COLOURING MATTERS AND DYES.

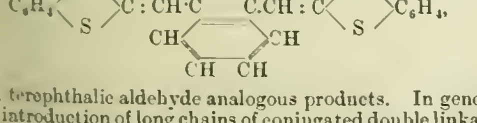
Indigoid dyestuffs. P. Friedländer and F. Risse. Ber., 1914, **47**, 1919—1929.

DYESTUFFS of the indigo type but with the group : CH.CH : introduced between the two symmetrical halves of the molecule show only insignificant differences in shade from the parent substances. Thus the dyestuff,



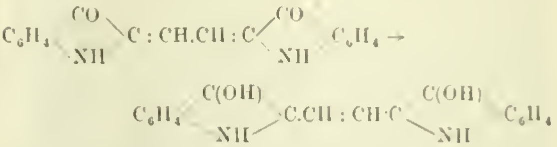
$$C_6H_4\left\langle\begin{matrix}CO\\NH\end{matrix}\right\rangle C : CH.CH : C\left\langle\begin{matrix}CO\\NH\end{matrix}\right\rangle C_6H_4,$$

which is obtained from indoxyl and glyoxal, hardly differs from indigo. Analogous products have been prepared from hydroxythionaphthene and glyoxal and from cumaranone and glyoxal. Just as an extra C_2H_2 residue is introduced above, so by the use of maleic aldehyde the residue : CH.CH : CH.CH : can be introduced into known types of dyestuffs. In a similar manner phthalic aldehyde gives dyestuffs of the type



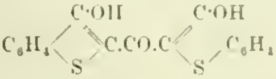
$$C_6H_4\left\langle\begin{matrix}CO\\S\end{matrix}\right\rangle C : CH{\cdot}C\underset{CH\quad CH}{\overset{}{\begin{matrix}\diagup\;\;\diagdown\\ CH\qquad CH\end{matrix}}}C.CH : C\left\langle\begin{matrix}CO\\S\end{matrix}\right\rangle C_6H_4,$$

and terephthalic aldehyde analogous products. In general the introduction of long chains of conjugated double linkages in this manner in the indigo series has the effect of displacing the shade of the dyestuff towards the violet end of the spectrum, instead of the expected deepening of the shade. With the exception of the cumaranone derivatives the new dyestuffs give vats with hydrosulphite and dye in the usual way. A displacement of the conjugated double linkages is probable, *e.g.*,



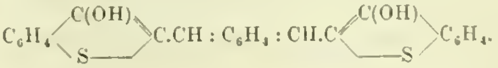
$$C_6H_4\left\langle\begin{matrix}CO\\NH\end{matrix}\right\rangle C : CH.CH : C\left\langle\begin{matrix}CO\\NH\end{matrix}\right\rangle C_6H_4 \rightarrow C_6H_4\left\langle\begin{matrix}C(OH)\\NH\end{matrix}\right\rangle C.CH : CH{\cdot}C\left\langle\begin{matrix}C(OH)\\NH\end{matrix}\right\rangle C_6H_4$$

The new leuco compounds are coloured intensely orange-yellow to orange-red like the analogous dihydroxydithionaphthene-ketone



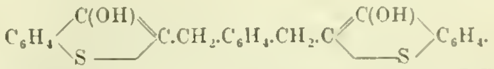
$$C_6H_4\left\langle\begin{matrix}C{\cdot}OH\\S\end{matrix}\right\rangle C.CO.C\left\langle\begin{matrix}C{\cdot}OH\\S\end{matrix}\right\rangle C_6H_4$$

whence it would appear that the .CH : CH. and the .CO. group have the same tinctorial effect. The new dyestuffs from phthalic and terephthalic aldehydes give colourless vats which oxidise first to a blue and then to the original orange-red. This suggests an intermediate quinonoid reduction phase,



$$C_6H_4\left\langle\begin{matrix}C(OH)\\S\end{matrix}\right\rangle C.CH : C_6H_4 : CH.C\left\langle\begin{matrix}C(OH)\\S\end{matrix}\right\rangle C_6H_4.$$

giving finally,



$$C_6H_4\left\langle\begin{matrix}C(OH)\\S\end{matrix}\right\rangle C.CH_2.C_6H_4.CH_2.C\left\langle\begin{matrix}C(OH)\\S\end{matrix}\right\rangle C_6H_4.$$

—J. B.

Anthanthrone. I. L. Kalb. Ber., 1914, **47**, 1724—1730.

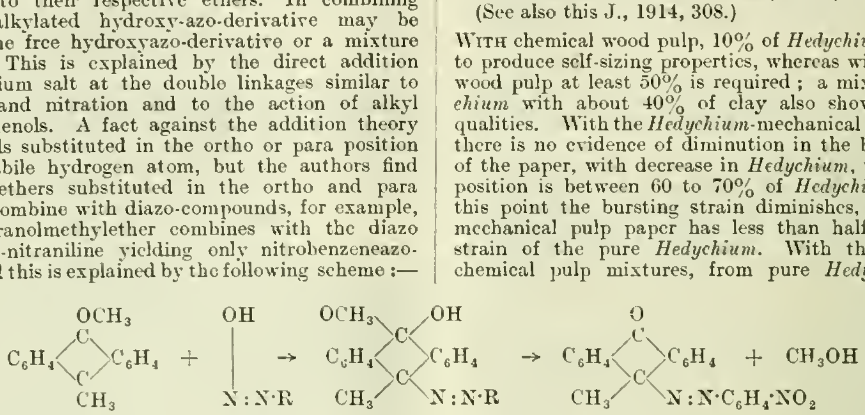
1-1′-DINAPHTHYL-8-8′- and 2-2′-dicarboxylic acids, on treatment with acid condensing agents such as sulphuric acid, chlorosulphonic acid, or aluminium chloride, both yield the same new quinone called "anthanthrone." Fusion of the carboxylic acids with alkali yields the quinone together with a hydroxy-derivative. Anthanthrone is a characteristic, orange coloured, vat dyestuff, soluble in aniline, very slightly soluble in ether, acetic acid, alcohol and benzene, giving pure yellow coloured solutions, and crystallises from nitrobenzene in orange coloured flat spears melting above 300° C. It dyes cotton orange yellow shades of excellent fastness to alkalis and oxidising agents.—G. H. F.

Azine, azoxine and thiazine dyestuffs; The constitution and colour of ——. Quinone-imide dyestuffs. III. F. Kehrmann, E. Havas and E. Grandmougin. Ber., 1914, **47**, 1881—1903.

THE absorption in the visible and invisible portions of the spectrum of a large number of dyestuffs of the above groups has been determined. The tinctorial effects observed with a series of salts of the dyestuffs, with increasing concentration of acid in the solution, agree with the theories as to the constitution of such salts previously advanced by the authors. (See this J., 1913, 783, 973, 1061.)—J. B.

Phenols and phenol ethers; Combination of —— with diazo-compounds. K. H. Meyer, A. Irschick and H. Schlösser. Ber., 1914, **47**, 1741—1755.

FROM a study of the ease with which various diazo-compounds combine with phenols and their ethers, it is shown that combination takes place most readily the more "negative" are the substituted groups in the diazo-compound. Thus the diazo-salt of *op*-dinitroaniline combines instantaneously in acetic acid solution with resorcinol and naphthol ethers, while diazo-benzene does not combine therewith. If the negative group is in the phenol ether, as in *p*-nitroanisol, naphthol-ethersulphonic acid or carboxylic acid, or *p*-nitronaphthol-ethylether, combination is hindered, taking place only very slowly or not at all. The following compounds are arranged in the order of the facility with which they combine: phloroglucinol, α-naphthol, resorcinol, β-naphthol, pyrocatechol, phenol, quinol, *o*-nitrophenol. This order applies also to their respective ethers. In combining ethers the alkylated hydroxy-azo-derivative may be formed, or the free hydroxyazo-derivative or a mixture of the two. This is explained by the direct addition of the diazonium salt at the double linkages similar to bromination and nitration and to the action of alkyl iodides on phenols. A fact against the addition theory is that phenols substituted in the ortho or para position contain no labile hydrogen atom, but the authors find that phenol ethers substituted in the ortho and para positions do combine with diazo-compounds, for example, *p*-methylanthranolmethylether combines with the diazo hydrate of *p*-nitraniline yielding only nitrobenzeneazo-anthranol, and this is explained by the following scheme :—



In support of the addition theory the authors find that unsaturated hydrocarbons give compounds with diazonium salts.—G. H. F.

Selenazine dyestuffs. H. Bauer. Ber., 1914, **47**, 1873—1881.

1.3-Dinitroselenazine is obtained by condensing picryl chloride with *o*-aminoselenophenol and closing the ring with loss of a mol. of nitrous acid by boiling in alcoholic alkaline solution. Further nitration of this substance gives 1.3.6-trinitro-selenazine. Reduction of the nitro-compounds and oxidation with ferric chloride gives 1.3-diamino- and 1.3.6-triamino-phenazselenonium chlorides. The former gives a brown-green, the latter a violet solution in water. On tannin-mordanted cotton the triamino dyestuff gives a bluer shade than the corresponding thiazine. The selenazines show the same behaviour towards trypanosomes as the oxazines and thiazines.—J. B.

Tri-indylmethane dyestuffs. IV. A. Ellinger and C. Flamand. Z. physiol. Chem., 1914, **91**, 15—20.

The dyestuff obtained by the authors by boiling β-indole-aldehyde with acid (this J., 1909, 1120) and described as a tri-indylmethane derivative has been subsequently stated to be a methylindylmethylindolidenmethane derivative by König (Z. angew. Chem., **22**, 1967; J. prakt. Chem., [2], **84**, 194), who obtained it by acting on methyl-indole-aldehyde with acid and also by acting on 2 mols. of methylindole with one mol. of orthoformic ester and the calculated quantity of concentrated acid. Scholtz (Ber., 1913, **46**, 2138, 2539) has come to the same conclusion as König, preparing the dyestuff from methylindole and formic acid. By heating the aldehyde with dilute acid or by a modification of Scholtz's method the authors have obtained a dyestuff (dimethylindylmethylindolidenmethane) which is closely related to the leuco compound of trimethylindylmethane. Further a tri-indylmethane derivative has now been prepared from indole-aldehyde and B_3-chloro-Pr_2-methylindole, which gives yellowish red salts and a yellow colour-base. There is a possibility here of the splitting-off of a mol. of chloromethylindole with the formation of a dyestuff of the indylindolidenmethane group, but the analysis agrees closely with the figures for a tri-indylmethane. It is not unlikely that the constitution of the product is largely influenced by the conditions of reaction, *e.g.* concentration of acid, so that the different investigators have been dealing with mixtures of dyestuffs of varying composition.—J. B.

V.—FIBRES ; TEXTILES ; CELLULOSE ; PAPER.

Hedychium pulp ; Influence of the addition of —— to chemical and mechanical wood pulps upon the physical qualities of paper produced therefrom. C. Beadle and H. P. Stevens. Chem. News, 1914, **109**, 280—281. (See also this J., 1914, 308.)

With chemical wood pulp, 10% of *Hedychium* is sufficient to produce self-sizing properties, whereas with mechanical wood pulp at least 50% is required ; a mixture of *Hedychium* with about 40% of clay also showed self-sizing qualities. With the *Hedychium*-mechanical pulp mixtures, there is no evidence of diminution in the bursting strain of the paper, with decrease in *Hedychium*, until the composition is between 60 to 70% of *Hedychium*, but from this point the bursting strain diminishes, and the pure mechanical pulp paper has less than half the bursting strain of the pure *Hedychium*. With the *Hedychium*-chemical pulp mixtures, from pure *Hedychium* up to mixtures containing 50% of chemical pulp there is a gradual increase in the bursting strain, and from this point to the pure chemical wood pulp paper there is a corresponding gradual decrease.—B. N.

Uses of collodion in leather finishing. Higgins. *See* XV.

Patents.

Cellulose esters of organic acids ; Manufacture of ——. Act.-Ges. für Anilinfabrik., Treptow, Germany. Eng. Pat. 1156, Jan. 15, 1914. Under Int. Conv., Jan. 14, 1913. Addition to Eng. Pat. 10,706, May 6, 1912 (this J., 1913, 482).

Cellulose derivatives, made by the action of more or less concentrated nitric acid on cellulose, are treated by the usual methods of esterification for producing cellulose esters.—B. N.

[*Viscose*] *Threads, films and the like ; Manufacture of ——.* F. Steimmig, Hanover, Germany. Eng. Pat. 5238, Feb. 28, 1914.

The viscose is squirted into a warm highly-concentrated solution of a neutral salt containing a small percentage of a soluble ammonium salt, and the thread is then exposed to the air for some time (see also Eng. Pat. 11,104 of 1913 ; this J., 1913, 1153).—B. N.

Paper-pulp ; Production of ——. The Watford Engineering Works, Ltd., and J. Paramor, Watford. Eng. Pats. 19,427 and 24,930, Aug. 27, and Nov. 1, 1913.

The machine comprises a steeping chamber and a cylindrical pulping-barrel, traversed by a rotating shaft carrying beating arms. The latter, within the steeping chamber, are carried upon a hollow shaft mounted upon the rotating shaft, with means whereby the relative speeds of the two may be varied to suit particular conditions of working. A stirrer shaft, provided with arms or projections, is also arranged in the lower part of the steeping chamber, and the portion of the pulping-barrel adjacent to the steeping chamber is of a diameter greater than the remainder. —B. N.

Paper ; Drying and surface finishing of ——. C. E. Pope, Holyoke, Mass., U.S.A. Eng. Pat. 2847, Feb. 3, 1914.

Hollow rotating drying drums are arranged in two tiers each provided with an endless apron to guide the web of paper round the drums, and with pressure rolls which bear directly upon the aprons and press the web of paper against the drums. The pressure may be varied by rotatable adjustable cams, which press against the bars carrying the pressure rolls. The guide rolls, for the looped portions of the aprons, are so set with respect to the two tiers of rolls, as to shorten the gaps which the end of the paper must traverse in passing from a lower to an advanced upper drum in starting after a break. The paper is thus gradually dried and finished, which gives it a suitable printing surface without subsequent calendering. —B. N.

Manufacture of products [alginates] from seaweed, and treatment of paper, textiles, etc., with such products. Eng. Pat. 13,777. *See* VI.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Wool; The action of solutions of Glauber's salt on——. M. Fort. J. Soc. Dyers and Col., 1914, **30**, 228—231.

A reply to Herz and Barraclough (this J., 1914, 479). It is shown that exact tintometric determination of the strength of the dyeings obtained by Herz and Barraclough confirm the author's conclusions that the effect of sodium sulphate in dyeing acid dyestuffs from a neutral bath is to increase the amount of dyestuff taken up. The author adheres to his opinion that the injury to the lustre of wool in dyeing in the Glauber's salt bath is caused by loss of wool substance from the fibre due to a reaction between the salt and the wool.—J. B.

Wool; Sorption [absorption and adsorption] of some acids and non-electrolytes by——. A. Dietl. Kolloid-Zeits., 1914, **14**, 319—321.

Von Georgievics (this J., 1914, 251) has shown that in the sorption of acids by wool, the value of the exponent x in Boedecker's distribution formula, which may be taken as a measure of the amount of adsorption, varies in the same way as the strength of the acids. Walker and Appleyard (this J., 1896, 650) found that aromatic acids were more strongly absorbed than other acids, and the author therefore made experiments with salicylic and benzoic acids and also with phosphoric acid. The results show that though these acids are strongly absorbed by wool, the values of x are smaller than in the case of stronger mineral acids, and are in agreement with von Georgievics' rule. Moreover, acetone and sucrose, which, as non-electrolytes should be only slightly adsorbed, gave abnormally low values for x, viz., about 1·47 and 1·1 respectively, indicating that in these cases the absorption is due mainly to the formation of solid solutions; the total sorption is low in the case of acetone and sucrose.—A. S.

Silk-weighting with stannic chloride; The theory of——. F. Fichter and E. Müller. Chem.-Zeit., 1914, **38**, 693—694.

Silk was found to take up stannic chloride in a fixed proportion from a solution of the salt in benzene whatever the concentration of the latter. Adsorption is unlikely here on account of the low surface tension of the benzene and the experiment is considered a confirmation of the theory of chemical combination, in opposition to the views of Sisley and Ley (Chem.-Zeit., 1911, 621; 1912, 1405 and 1466; this J., 1913, 81). The authors' theory is that an addition product is formed between the amino-acid —fibroin—of the silk and the tin salt. They have isolated such addition products in the case of the analogous substances alanin and glycocoll. They have the constitution $Sn(amino\ acid)_4Cl_4$. They are very soluble in water and undergo progressive hydrolysis, the amino-acid and chlorine being gradually replaced by hydroxyl until finally stannic hydroxide is left. Analogous addition products are probably formed in silk-weighting, hydrolysis taking place in the washing, at the end of which process the fibroin is restored to its original condition and is ready to take up a fresh charge.—J. B.

Grey; Fast steam——. E. Justin-Mueller. Sealed Note, No. 2047, dated Oct. 22, 1910. Report thereon by C. Favre. Bull. Soc. Ind.-Mulhouse, 1914, **84**, 217—220.

Hydron Blue G and R is transformed by treatment with bisulphite into a grey which when printed with chromium acetate gives shades perfectly fast to soap and chlorine. Other reducing agents acting on Hydron Blue in slightly acid mediums also give greys (for instance, stannous chloride, glucose and sugar), but differing somewhat in properties from the bisulphite grey. The report states that these dyestuffs also give greys when printed simply with chromium acetate by Bayer und Co.'s process, though the shade is not so good.—J. B.

[Printing.] Fixing dyestuffs on cotton; New process for——. P. Doane. Sealed Note, No. 1305, dated Dec. 4, 1901. Report thereon by H. Schmid. Bull. Soc. Ind. Mulhouse, 1914, **84**, 215—217.

A basic dyestuff (*e.g.*, Thionine Blue, Thioflavin) is printed together with a caustic soda solution of zinc ferrocyanide and, after drying, the cloth is passed into acid, whereby a fast lake is formed without steaming. The process is a modification of the old method of forming lakes on a zinc ferrocyanide mordant first described by C. Reben and afterwards applied for illuminating Aniline Blacks and azo colours by W. E. Key and The Thornliebank Co., Glasgow (Eng. Pat. 713 of 1893; this J., 1893, 1027), and for illuminating Naphthylamine Bordeaux by F. Oswald in 1893 (this J., 1894, 1193).—J. B.

Light on dyed fabrics; The action of——. W. Harrison. J. Soc. Dyers and Col., 1914, **30**, 206—211.

A reply to criticism by Gebhard (Chem.-Zeit., 1913, 601, 622, 638, 662, 679, 717, 765) of the author's theory (see this J., 1912, 681) that the fading of dyed cotton is due to the reducing action of the products of decomposition of cellulose. These decomposition products appear to be of an acid character and are possibly hydroxy-acids like tartaric acid. Dyed cotton faded more quickly if treated with tartaric acid before exposure; also cotton which had been exposed to light from a mercury vapour lamp until slightly tendered was found after dyeing with a benzene solution of picric acid to fade much more rapidly when exposed to sunlight *in vacuo* than did an untreated pattern. Gebhard's theory of auto-oxidation (this J., 1910, 691) is also discussed.—J. B.

Patents.

Mercerisation; Process for cleansing the lye used in—— from size and other organic substances. J. Matter, Laacken, Germany. Eng. Pat. 28,250, Dec. 8, 1913.

Organic impurities are precipitated by treating the mercerising liquor with a finely divided silicate (*e.g.*, kaolin, china-clay, pumice, talc, white bole, etc.) and allowing to settle without heating. The process may be advantageously worked in conjunction with the gypsum-lime process.—J. B.

Cheeses, cops and similarly wound forms of woollen and worsted yarn; Treating—— preparatory to dyeing or bleaching. H. Heymann, Bradford. Eng. Pat. 19,522, Aug. 28, 1913.

The yarn is first degreased by passing a volatile solvent through the cheese, cop or similarly wound form, and the pure solvent remaining is removed by a vacuum pump and condensed.—B. N.

Products [alginates] from seaweed; Manufacture of—— and the treatment of paper, textiles, leather, or the like, with such products. T. Ingham, Liverpool. Eng. Pat. 13,777, June 14, 1913.

Soluble double metallic alginates, such as those of aluminium, zinc, iron, cadmium, copper, or the like, with ammonium, sodium, or potassium, are prepared by treating an alginate solution with an excess of an alkali hydroxide, or carbonate, and then adding a soluble metallic salt, sufficient to normally precipitate the whole of the alginic acid in the mixture. The product is employed for treating or finishing paper, textile fabrics, etc., and a water-repelling substance, such as wax, tallow or linseed oil, is added to render the material waterproof. —B. N.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Platinum vessels: Resistance of —— to hot nitric acid. G. P. Baxter and F. L. Grover. J. Amer. Chem. Soc., 1914, **36**, 1089—1091.

Experiments are described which show, in contradiction to the evidence of Jannek and Meyer (Z. anorg. Chem., 1913. **83**, 51), that hot concentrated nitric acid extracts practically nothing from pure, well-cleaned platinum. Residues obtained after the evaporation of nitric acid which had been distilled through platinum condensers are probably due either to traces of hydrochloric acid in the acid or to the inefficient cleansing of the condenser or of the platinum vessels used for the evaporation.—G. F. M.

Sulphates; Volumetric determination of ——. H. North. Amer. J. Pharm., 1914, **86**, 249—256.

A modification of the chromate method (compare this J., 1910. 455, 902), designed to avoid the carrying down of soluble chromate with the barium chromate precipitate. The solution containing about 0·16 grm. SO_4, is diluted to 30 c.c., treated with sufficient hydrochloric acid (sp. gr. 1·12) to bring the total amount present to 4 c.c., and heated to boiling; 20 c.c. of $N/3$ barium chloride and, after again boiling, 10 c.c. of $N/1$ potassium bichromate are added, then 10 c.c. of rinsing water and a mixture of 15 c.c. of ammonia (sp. gr. 0·98) and 2 c.c. of 36% acetic acid, drop by drop, with constant shaking. The mixture is cooled, diluted to 100 c.c., filtered through asbestos (dried at 110° C.), and 40 c.c. of the filtrate treated with 1 grm. of potassium iodide dissolved in 20 c.c. of dilute sulphuric acid (1 : 9, by volume); 40 c.c. of rinsing water are added, the covered flask allowed to stand for 6 minutes, 150 c.c. of water introduced, and the liberated iodine titrated with $N/10$ thiosulphate. The number of c.c. of thiosulphate, multiplied by the factor 0·008, gives the weight (grms.) of SO_4 originally taken. The barium chloride solution (10 c.c., with 4 c.c. of hydrochloric acid and 40 c.c. of water) is standardised as above, and the thiosulphate likewise checked by adding 20 c.c. of $N/10$ bichromate to potassium iodide (1 grm. in 20 c.c. of dilute sulphuric acid) and titrating as described, 60 c.c. of rinsing water being used in place of 40 c.c. With less than 0·16 grm. SO_4, 0·3 c.c. of $N/10$ thiosulphate should be deducted for every 40 c.c. of filtrate, owing to the slight solubility of barium chromate. The solution may contain the ions $Li^{\cdot}$, $Na^{\cdot}$, $K^{\cdot}$, $NH_4^{\cdot}$, $Cu^{\cdot\cdot}$, $Mg^{\cdot\cdot}$, $Ca^{\cdot\cdot}$, $Zn^{\cdot\cdot}$, $Cd^{\cdot\cdot}$, $Hg^{\cdot\cdot}$, $Al^{\cdot\cdot\cdot}$, $Ni^{\cdot\cdot}$, $Co^{\cdot\cdot}$, Cl', PO_4''' (in limited amount), and B_4O_7'', but not iron. A determination may be made in 50 minutes. —F. Sodn.

Disodium phosphate; Reduction of —— by alternating electric currents. P. Wenger and L. Heinen. Ann. Chim. Analyt., 1914, **19**, 209—211.

The effects of time, temperature, and concentration on the reduction of disodium phosphate by the action of an alternating current are recorded. With a 1% solution of the salt at 18° C., the amount reduced increases from 1·05% in 1 hour to 8·34% in 5 hours; the reduction also increases with rise of temperature, 2·59% being reduced in 1 hour at 80° C. When the concentration of the phosphate solution is increased, the amount reduced diminishes considerably; for instance, with a 10% solution, only 0·1% is reduced in 1 hour at 18° C. Copper electrodes were used, and practically the same results were obtained with stationary as with rotating electrodes. The phosphite produced by the reduction was estimated by titration with iodine in the presence of sodium bicarbonate.—W. P. S.

Fluorides; Action of weak acids on soluble ——. P. A. E. Richards. Analyst, 1914. **39**, 248—250.

Lactic, butyric, tartaric, malic, citric, formic, salicylic, and benzoic acids all liberate hydrofluoric acid from potassium and sodium fluorides, the reaction taking place even with 1% solutions of the acids. Carbon dioxide also liberates hydrofluoric acid from these fluorides, but none of the acids mentioned attacked calcium fluoride. —W. P. S.

Cyanides; Detection of —— in presence of ferro- and ferricyanides and thiocyanates. O. L. Barnebey. J. Amer. Chem. Soc., 1914, **36**, 1092—1093.

The test is based upon the solubility of copper sulphide in alkali cyanides. A suspension of copper sulphide is made by passing a few bubbles of hydrogen sulphide into a weak ammoniacal solution of copper sulphate, and if the colour is discharged on the addition of an ammoniacal solution of the substance, the presence of a cyanide is indicated. By using a sufficiently dilute copper solution, the test has a delicacy of 1 part of hydrocyanic acid in 10,000, and it is not seriously interfered with by the presence of ferro- or ferricyanides or thiocyanates. In presence of 2 grms. of these substances, 0·5, 1, and 0·5 mgrm. respectively of hydrocyanic acid can be detected. By using a standard copper solution the test can be utilised for a rough quantitative determination if only cyanides are present.—G. F. M.

Ferricyanides in presence of ferric iron and cyanides; Volumetric determination of ——. E. Müller and F. Seidel. Z. anal. Chem., 1914, **53**, 416—420.

To suppress the liberation of iodine by ferric iron, potassium fluoride is added to the feebly acid solution of the ferricyanide in the proportion of 6 grm.-atoms of fluorine to 1 of iron. Potassium iodide and zinc sulphate are then added, and the liberated iodine titrated with thiosulphate. Any hydrocyanic acid present is first removed by passing a current of carbon dioxide free from reducing substances through the liquid warmed to 50° C. and made acid with sulphuric acid.—O. E. M.

Cyanamide; Volumetric determination of ——. G. Grube and J. Krüger. Z. angew. Chem., 1914, **27**, 326—327.

The cyanamide solution is diluted to 300 c.c., acidified with 1 c.c. of $2N$ nitric acid, 50 c.c. of $N/10$ silver nitrate added, and the solution made just alkaline to litmus by adding 2% ammonia. Yellow silver cyanamide, $CNNAg_2$, is precipitated. The mixture is made up to 500 c.c., and the excess of silver determined in 250 c.c. of the filtrate by titration with thiocyanate. The results agree with those obtained by Caro's method of determination of nitrogen in the silver cyanamide by Kjeldahl's process (this J., 1911, 23).—W. R. S.

Nitrogen compounds of nitrolim (crude calcium cyanamide); Solubility of the —— in water. C. Manuelli. Annali Chim. Appl., 1914, **1**, 412—413.

Four grms. of nitrolim (N 20·25%) were mixed with 100 c.c. of water and kept at a constant temperature of 13·2°—13·4° C. After one hour about 80% and after 6 hours 88% of the total nitrogen had passed into solution; after this the amount of dissolved nitrogen began t diminish, evidently owing to the transformation o cyanamide into the sparingly soluble dicyanodiamide A sample of granulated nitrolim (N 12·88%) gave simila results, 79% of the total nitrogen being dissolved in 1 hou and 90% in 8 hours.—A. S.

Calcium cyanamide into ammonia; Transformation of —— C. Manuelli. Annali Chim. Appl., 1914, **1**, 388—396.

Although the conversion of the nitrogen of calciun cyanamide into ammonia by the action of steam unde pressure at 170° C. is the basis of a commercial proces carried out on the large scale in Italy, Belgium, German France and Japan, no published data as to the yield ammonia are available. In the author's experiments weighed quantities (usually 100 grms.) of nitrolim (crude calcium cyanamide) were intimately mixed with water and then heated with excess of water under pressure in an autoclave for 6—8 hours at 170°—180° C. Yields of about 90% of the theoretical quantity of ammonia were obtained and these could be increased to 97—99% by using only 10 grms. of nitrolim or by repeating the treatment. In practice, using an autoclave provided with an agitator to prevent formation of hard lumps, nearly theoretical yields of ammonia could be obtained. The cost of fuel, sulphuric acid, and labour for converting the nitrogen of nitrolim into ammonium sulphate by this process would be about 20 centimes per kilo. of nitrogen (0·86d. per lb.).—A. S.

Ammonia ; Anodic oxidation of —— in alkaline solution in presence of silver salts. G. Scagliarini. Gaz. chim. ital., 1914, **44**, I., 543—547. (See also this J., 1913, 138.)

Experiments on the electrolytic oxidation of ammonia, in presence of silver sulphate, in a solution to which potassium hydroxide was added, showed that, as in the experiments of Müller and Spitzer (this J., 1905, 279, 550) in presence of copper salts, with high concentrations of free alkali the oxidation was almost exclusively to nitrous acid. The yield of nitrous acid increased considerably as the concentration of the ammonia solution was diminished and that of potassium hydroxide increased ; it also increased somewhat with rise of temperature up to 52° C. and with increase in the concentration of silver sulphate. The highest yield of nitrous acid recorded (11·92 grms. per 100 grms. NH_3) was obtained in 4 hours at 30° C., using a current density of 2·5 ampères at 20 volts, the cathode liquid being a 3% solution of ammonia and the anode liquid 200 c.c. of a 3% solution of ammonia, 30 c.c. of a 25% solution of potassium hydroxide and 2 grms. of silver sulphate.—A. S.

[*Silicates, borates, etc.*] *Spontaneous crystallisation ; A method of inducing ——.* G. Tammann. Z. anorg. Chem., 1914, **87**, 248—252.

The method consists in heating one end of a column of the material to a temperature above the melting point, the other end being unheated. The material is contained in a receptacle of high heat conductivity to diminish as far as possible the steepness of the temperature gradient. Under these conditions, after some time, a turbidity due to incipient crystallisation will be observed in that part of the column between the temperature of maximum crystallisation velocity and that of maximum power of spontaneous crystallisation (see Z. physik. Chem., 1898, **25**, 441). The zone of turbidity gradually becomes larger and crystals (usually spherolites) visible to the naked eye separate. If the material is contained in a glass tube this may be cut at the zone of turbidity, and the crystals added to a mass of the material heated to a temperature somewhat above that at which the crystals formed, whereupon by vigorous stirring, the whole mass can be made to crystallise. By this method of heating a column of the material at one end only, fine needles containing 10·89% Na were obtained from a fused mixture of B_2O_3.66 and $Na_2B_4O_7$ 34%, and large transparent crystals of K_2SiO_3 from a mixture of equivalent proportions of potassium carbonate and silica.—A. S.

Thorium : New method for the determination of —— in monazite sand. R. J. Carney and E. D. Campbell. J. Amer. Chem. Soc., 1914, **36**, 1134—1143.

The method depends upon the complete precipitation of thorium pyrophosphate by means of sodium pyrophosphate in acid solution. The pyrophosphates of cerous cerium and of the other rare earth metals with the exception of zirconium are soluble in acid and remain in solution. The sand is first decomposed with concentrated sulphuric acid (Meyer and Speter, this J., 1910, 486), and an aliquot portion of the diluted and filtered solution, representing about 2·5 grms. of the mineral, is diluted to 450 c.c., acidified with 5 c.c. of hydrochloric acid and 15 c.c. of 5% solution of sodium pyrophosphate added. After boiling, the precipitate of thorium and zirconium pyrophosphates (containing also traces of ceric and other pyrophosphates mechanically brought down) is filtered off and converted into sulphate by digestion on the filter paper in a Kjeldahl flask with 15 c.c. of concentrated sulphuric acid and a few crystals of ammonium perchlorate. After cooling the clear solution is diluted and the hydroxides are precipitated with sodium hydroxide. These are then after filtration dissolved in hydrochloric acid, a few c.c. of concentrated sulphur dioxide solution added to reduce any ceric cerium, and the phosphate precipitation and subsequent conversion into sulphate and hydroxide repeated. The hydroxides of thorium and zirconium are dissolved in hydrochloric acid and the thorium precipitated from this solution as oxalate by the addition of 2 grms. of oxalic acid. The solution is diluted to 450 c.c. and allowed to stand over night. The pure thorium oxalate is then filtered off, and ignited and weighed as oxide. The oxide obtained was always quite white, and free from phosphate and from cerium. The results of analyses both of mixtures of thoria with pure rare earth salts, and of various samples of monazite demonstrated the reliability of the method, and they were in close agreement with those obtained by the iodate method of Meyer and Speter.
—G. F. M.

Lanthanum and the didymiums ; Action of bromine on ——. P. E. Browning. Comptes rend., 1914, **158**, 1679—1680.

Of the hydroxides of the cerium group of metals remaining after removal of the ceria by the method previously described (this J., 1910, 210), that of lanthanum dissolves most readily in bromine water. This property can be utilised for the separation of lanthanum from neodymium and praseodymium, three treatments sufficing for an almost complete separation. The method is more rapid than that of fractional crystallisation of the double nitrates of the metals and ammonium, though the latter gives better results in the final stages of purification.
—L. E.

Tungstic acid by means of "nitron" ; Separation and determination of ——. A. Gutbier and G. L. Weise. Z. anal. Chem., 1914, **53**, 426—430. (See also this J., 1905, 289, 291, 638.)

The weighed tungstic acid is moistened with water and dissolved with the aid of heat in the smallest possible quantity of concentrated sodium hydroxide solution. The clear liquid is diluted to about 150 c.c. with boiling water, rendered acid with acetic acid, precipitated, while being vigorously stirred, with a small excess of "nitron" (diphenyl-*endo*-anilinodihydrotriazole) acetate solution, and at once allowed to cool. The precipitate is washed with a 0·4% solution of "nitron" acetate, ignited at 890° C. and weighed as tungsten trioxide.—O. E. M.

Uranyl thiocyanate. P. Pascal. Comptes rend., 1914, **158**, 1672—1674.

Uranyl thiocyanate is obtained by mixing cold solutions of equimolecular quantities of uranyl sulphate and barium thiocyanate, filtering, and evaporating the filtrate *in vacuo* over sulphuric acid. The pasty mass thus obtained yields, in the course of some days, orange yellow needles of the compound, $UO_2(CNS)_2+8H_2O$. This salt, which is extremely deliquescent, is very soluble in water, ethyl and amyl alcohols, acetone, and ether. It is strongly ionised in aqueous solution, and is hydrolysed on heating the solution to 100° C. Uranyl thiocyanate forms double salts with alkali and alkaline-earth thiocyanates, *e.g.* :— $UO_2(CNS)_2,3NH_4CNS,6H_2O$; $UO_2(CNS)_2,5NH_4CNS,2H_2O$; and $UO_2(CNS)_2,Ba(CNS)_2,6H_2O$, which are very unstable, none of them, in aqueous solution, presenting the character of a complex salt.—L. E.

Hydrogen peroxide ; The photochemical decomposition of ——. J. H. Mathews and H. A. Curtis. J. Phys. Chem. 1914, **18**, 521—537. (See this J., 1914, 352.)

Acetamide, urea, boric acid and barium chloride had practically no effect on the photolysis of hydrogen peroxide ;

acetic, tartaric and phosphoric acids, sodium chloride, potassium chloride and potassium nitrate were slightly or mildly inhibitive, as also was sulphuric acid of concentrations varying from 0·00176*N* to 0·0349 *N*; barium nitrate acted as a positive, and benzoic acid as a strongly negative, catalyst. The thermal and photochemical decompositions were not similarly affected by the same catalyst. —W. E. F. P.

Metallic oxides and hydroxides; Behaviour of some —— with solutions of ethylene-diamine; W. Traube and B. Loewe. Ber., 1914, **47**, 1908—1919.

Ethylenediamine is known to dissolve certain metallic hydroxides in definite molecular proportions, but the products have not previously been isolated in the solid form. The authors have obtained the compound triethylenediamine nickel hydroxide, $[Ni(C_2H_8N_2)_3](OH)_2+8H_2O$, in the pure state by evaporating the solution obtained either by shaking powdered nickel with ethylenediamine and oxygen or by the addition of barium hydroxide to triethylenediamine nickel sulphate. The corresponding bases derived from other metals decomposed on evaporation, but evidence was obtained that the hydrogen of the amino groups can be completely replaced by copper, and that two of the four hydrogen atoms can be replaced by silver. Mercuric iodide and cadmium hydroxide dissolve in ethylenediamine in indefinite proportions; in presence of oxygen cobalt yields a solution containing one atom of trivalent metal to two mols. of the amine. A divalent cobalt derivative was obtained in solution by the action of cobalt on the copper compound in absence of oxygen. On admission of oxygen the cobalt passed quantitatively to the trivalent condition.—O. E. M.

Colloidal carbon obtained by a chemical method. L. Sabbatani. Kolloid-Zeits., 1914, **14**, 29—31.

Two grms. of finely powdered sugar are added, gradually, during 2 hours, to 20 c.c. of concentrated sulphuric acid, with constant agitation, and the mixture allowed to stand at the ordinary temperature. After 24 hours the viscous, deep black liquid is poured gradually, with agitation, into 80 c.c. of water, the solution filtered, and dialysed until free from sulphuric acid. The clear, black solution of colloidal carbon thus obtained is very stable; the colloidal particles have an electro-negative charge. Gelatinous carbon is obtained by mixing the sugar and acid as described above, shaking for 2 hours, allowing to stand for 3—4 days at the ordinary temperature, then pouring into a shallow vessel and leaving it together with a vessel of water under a bell. After 7—9 days the viscous solution is converted into a gelatinous mass, which is freed from acid by immersion in water, the latter being frequently changed. When withdrawn from the water and exposed to air, the jelly gradually shrinks and loses weight. After drying it forms a very hard, shiny mass, difficult to pulverise, and showing a conchoidal fracture. It swells slightly in water, and dissolves sparingly in alkalis, yielding a colloidal solution.—A. S.

Patents.

Sulphuric acid; Chambers used in the manufacture of ——. W. G. Mills, C. T. Packard, and E. Packard and Co., Ltd., Ipswich. Eng. Pat. 12,067, May 23, 1913.

The chamber is of the shape of a frustum of a cone or pyramid and is cooled by water flowing over the exterior, preferably from a series of perforated pipes surrounding the chamber at different heights to form a number of cooling zones. The water from each zone flows into a corresponding gutter which also surrounds the chamber and, being attached to the main framework as well as to the chamber itself, helps to support the walls.—F. Sodn.

Caustic alkalis from alkali carbonates; Manufacture of ——. E. Schütz. Ger. Pat. 272,790, April 19, 1913.

Alkali carbonate and quicklime are intimately mixed in the dry state, and the mixture treated with sufficient water to slake the lime. The heat developed is sufficient to ensure the conversion of half of the alkali carbonate into hydroxide, and the remainder is then causticised in the usual manner.—A. S.

[Zinc] Sulphate liquors; Process for the electrolysis and treatment of ——. E. J. Hunt, Oldbury, and W. T. Gidden, Warley. Eng. Pat. 11,634, May 19, 1913.

In the electrolysis of zinc sulphate solution containing free acid, with lead anodes, particles of undissolved lead compounds (peroxide and sulphate) are prevented from reaching the cathode by interposing a porous diaphragm (*e.g.*, of asbestos cloth) which allows sufficient circulation to ensure substantially the same electrolyte at the anode and cathode. Fresh supplies of electrolyte are prepared, preferably, by treating crude zinc oxide or carbonate with acid liquor free from suspended lead compounds and then agitating the solution with the separated peroxide, in order to remove iron and manganese.—F. Sodn.

Zinc sulphate liquors; Process for treating ——. E. J. Hunt, Oldbury, and W. T. Gidden, Warley. Eng. Pat. 2952 of 1914, date of Appl., May 19, 1913.

Crude zinc sulphate liquors intended for electrolysis are purified from ferrous iron and manganese by treating (preferably hot) with lead peroxide, obtained, for example, as described in Eng. Pat. 11,634 of 1913 (see preceding abstract). An alkali or metallic oxide or carbonate may be added to complete the separation.—F. Sodn.

Boron suboxide; Processes of producing ——. The British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 15,757, July 8, 1913.

An intimate mixture of a boron compound and oxidisable silicon material (*e.g.*, borax, 7—8 parts, and silicon, 1 part) is heated electrically to the boiling point of the charge in a refractory container, which is lined, preferably, with paper. The crushed product may be purified by boiling with sodium hydroxide solution (to remove uncombined silicon and by-products).—F. Sodn.

Cyanogen compounds; Process of preparing ——. J. E. Bucher, Coventry, R.I., Assignor to Nitrogen Products Co. U.S. Pat. 1,094,976, April 28, 1914; date of Appl., Dec. 18, 1912.

In the process of producing alkali cyanides by the interaction of alkali carbonate, carbon dissolved in iron, and atmospheric nitrogen, the iron acting as a catalytic agent (see Fr. Pat. 455,799 of 1912; this J., 1913, 943), the alkali cyanide when formed is removed from the reaction zone by distillation under diminished pressure.—A. S.

Sulphur; Process for obtaining —— by the interaction of sulphur dioxide and hydrogen sulphide. W. Feld. Ger. Pat. 272,474, Dec. 31, 1911.

The two gases, alone or mixed with other gases or vapours, or dissolved in liquids, are allowed to act simultaneously or successively on a solution of one or several thiosulphates of metals, the sulphides of which are soluble in water. For each part by weight of hydrogen sulphide one part or more of sulphur dioxide must be present, and if the gases contain also ammonia, an additional two parts of sulphu dioxide for each part of ammonia must be added. The polythionate produced by the excess of sulphur dioxide is reduced to thiosulphate by treating the solution with basic or reducing substances, *e.g.*, with gases or vapour containing hydrogen sulphide or ammonia or both. Thi may be effected by using the solution for removin ammonia or ammonia and hydrogen sulphide from gase by the process described in Fr. Pat. 431,241 (this J., 1911 1381). Any hydrogen sulphide remaining in gases which have been treated as described in Fr. Pat. 431,241 (*loc cit.*) may be removed as described above. The thiosulphat solution is diluted from time to time to maintain it activity.—A. S.

Hydrogen peroxide; Process for the cathodic production of —— in electrolytes containing oxygen or an oxygen-containing gas. Henkel und Co. Ger. Pat. 273,269, Aug. 5, 1913. Addition to Ger. Pat. 266,516.

In carrying out the process described in the chief patent (see Eng. Pat. 8582 and Fr. Pat. 457,696 of 1913; this J., 1913, 791, 1010), tantalum, tungsten, niobium, molybdenum, or a metal of the platinum group is used as cathode. Cathodes of these metals do not deteriorate in use as do the amalgamated gold cathodes described previously.
—A. S.

Hydrazoic acid or azides; Manufacture of ——. H. Standinger. Ger. Pat. 273,667, May 27, 1913.

Hydrazine hydrate or a hydrazine salt is treated with the nitrosamine of a secondary amine, such as diphenylamine, in alcoholic solution, in presence of caustic alkali or alkali carbonate. The reaction proceeds slowly in the cold, more rapidly on heating:—

$$(C_6H_5)_2N.NO+NH_2.NH_2+NaOH=(C_6H_5)_2NH+N_3Na+2H_2O.$$

—A. S.

VIII.—GLASS; CERAMICS.

Nitrates; Use of —— in the glass industry. L. Springer. Sprechsaal, 1914, **47**, 361—363.

The value of nitrates in glass-making depends on their oxidising, purifying and decolorising effects. They counteract the reducing action of the fire-gases and of sulphur dioxide in lead glazes and in colours dependent on chromates or manganates. On the other hand, nitrates are costly and strongly attack the hearth and walls of the furnace, with consequent solution of alumina in the glass. For this reason it is recommended that not more than 5 parts of saltpetre should be used with 100 of sand, and that not more than 15% of the total alkali content should be introduced as saltpetre, this proportion being reduced to 10% in the case of crystal glass.—H. H. S.

Gold; Use of —— in ceramics. A. Granger. La Céramique, 1912, 262 and 1913, 3; Sprechsaal, 1914, **47**, 359—360, 373—375.

Gold is used on pottery either for gilding or as a colouring agent in glazes. Its value for gilding lies in its resistance to oxidation and the fineness of layer which can be produced, for which reason it is not an expensive stain. The aid of a flux is employed in application, and mercurous oxide is found to reduce the amount of gold required. A mixing of the composition: 30 parts by weight of precipitated gold, 15 of black mercurous oxide, 2·5 of basic bismuth nitrate, and 0·3 of melted borax, is recommended; the addition of 3 parts of silver carbonate to this produces a greenish tint. After firing in the muffle the gold has a matt surface, and must be polished with bloodstone or agate. A cheaper process, which does not require polishing after the burn, is the use of "Glanzgold" or "Meissen gold," a preparation of gold solution with an organic medium such as turpentine, lavender oil and a balsam or resin. As a colouring agent in glazes, gold produces shades from violet to purple and red, of which the best known is purple of Cassius, a lake of precipitated gold with a metallic hydroxide, preferably that of tin, which was formerly regarded as a definite compound. The presence of ammonia or alum in the stannous chloride solution produces shades from dark to rose purple, and the tint may be further modified by the substitution of antimony or magnesia for tin. Choice of flux materially influences the colour; various recipes are given containing lead oxide, borax or felspar; and kaolin may be used as a base for the lake. In lead glazes 1 part of gold in 1000 parts of glaze powder will produce a deep red glaze; and in leadless glazes, 1 in 10,000. An underglaze stain can be produced from 50 parts of pegmatite, 50 of alumina and 1 of gold chloride. Gold may be applied under a glaze on places previously moistened with gum tragacanth solution.—H. H. S.

Lead problem; The ——. J. Dorfner. Sprechsaal, 1914, **47**, 390—391.

Leadless glazes are much more sensitive to firing conditions than those containing lead, and proper management of the burn is more important than molecular composition. The author recommends the following formulæ for a stoneware glaze fired at cones 010—07, the composition of the basic side being the most difficult of adjustment:—

	1	2	3	4	5	6
SiO_2 ..	2·5	2·2	2·02	2·52	2·447	2·245
Al_2O_3 .	0·255	0·23	0·21	0·393	0·105	0·292
B_2O_3 .	0·5	0·4	0·4	0.482	0·438	0·439
CaO ..	0·375	0·4	0·4	0·339	0·4	0·372
MgO .	0·175	0·1	0·2	—	0·055	0·112
Na_2O .	0·25	0·4	0·3	0·468	0.4	0·375
K_2O ..	0·125	0·1	0·1	0·193	0·145	0·141
ZnO ..	0·075	—	—	—	—	—

All these glazes fall within the limits prescribed by Pukall, who gives the general formula: R_2O, 0·1—0·4 R_2O_3, 0—0·5 B_2O_3, 2—4 SiO_2.—H. H. S.

Refractory materials [for gas retorts]. Bywater. *See* IIa.

Patents.

Glass; Ovens for the manufacture of sheet ——. Montan- und Industrialwerke vorm. J. D. Starck. Eng. Pat. 6357, March 12, 1914. Under Int. Conv., April 15, 1913.

In a spreading oven for the manufacture of sheet glass, the movements of the spreading trucks and of the traverser, or the movements of their driving parts, are transmitted to a switch gear controlling the driving motor and the change-over devices in the power transmission or driving gear, so as to ensure the automatic stopping of the motor as well as the automatic operation of the change-over devices of the driving gear. Electric clutches are thrown out of gear by means of a switch gear provided with a number of contacts corresponding to the four movements of the trucks and of the traverser, and comprising two contact rings mounted on a hollow spindle, one ring carrying the contacts used for reversing the driving motor, the other the contacts intended for throwing out of gear the clutches. Other claims refer to the driving of the trucks and to a grid conveyor.—H. H. S.

Silvering of mirrors and the like; Protecting ——. Marly Frères, Bordeaux, France. Eng. Pat. 10,006, April 22, 1914. Under Int. Conv., April 30, 1913.

To prevent deterioration of the foil of mirrors by friction during transport and manipulation, and adherence of silvered sheets of glass by contact, two distinct coatings are applied to the silver or to a suitable varnish previously spread over the silver. The first is an adhesive, resistant to chemicals, *e.g.*, guttapercha, certain tars, bitumens, or resins, gums or waxes, used at a temperature above the normal. The second consists of thin supple sheets, of paper for example, resistant to mechanical change, applied at a temperature sufficient to render the first coating pasty.—H. H. S.

Illuminating-glass; Method and batch or mixture for making ——. G. A. Macbeth, Assignor to Macbeth-Evans Glass Co., Pittsburgh, Pa. U.S. Pat. 1,097,600, May 19, 1914; date of Appl., May 9, 1913.

A foundation mixture capable of making substantially colourless clear glass (and preferably including a chloride) is fused with an aluminium compound and a fluoride, the weight of aluminium compound being greater than that of the fluorine, *e.g.*, 150 parts of foundation mixture, 9—15 of alumina, and 3—8 of the fluoride; the heating operation is stopped before the melt returns to a clear glass stage and before the specks are eliminated.—F. Sodn.

Glaze, slip, and the like; Apparatus for sifting and separating potter's ——. F. Beardmore, T. H. Gaskell and W. Boulton Ltd., Burslem, Staffs. Eng. Pat. 12,284, May 27, 1913.

A COMPACT apparatus contained in one frame comprises a sifting device, a pump for circulating the slip, and one or more dipping tubs, together with valved pipe connections so that the slip can be pumped to the sifter and from the dipping tubs back to the sifter. A magnetic separator may be provided for removing metallic particles from the slip during circulation.—H. H. S.

IX.—BUILDING MATERIALS.

Cement plants; Determination of the dust fall in the neighbourhood of ——. J. P. Mitchell. J. Ind. Eng. Chem., 1914, **6**, 454—459.

METHODS in which the air is passed through box-like chambers or through filters give the quantity of dust present but not the amount which would be deposited under normal conditions. The author uses glass plates coated with vaseline which are exposed on horizontal platforms mounted at the top of poles at a height of 25—30 ft. After exposure the plates are cleaned with gasoline, the dust recovered by filtration, and incinerated. From analyses of the dust thus obtained, of field dust obtained in a similar manner at a place outside the possible path of the cement-dust, and of dust issuing from the stack of the cement plant, the approximate relative proportions of "field dust" and "cement dust" in the collected samples are calculated. In some determinations made by this method the fall of cement dust calculated to lb. per acre per day varied from 0·4 to 10·4 at different stations according to the direction of the wind and other conditions.—A. S.

Magnesia and dolomitc Portland cements and their properties. M. v. Glasenapp. Chem.-Zeit., 1914, **38**, 589.

THE calcium oxide in Portland cement was replaced by an equivalent quantity of magnesia, the clinker then containing 59% MgO and 41% silicate. To effect solution of the magnesia in the silicate a much higher temperature (1700°—1800° C.) was required than in the case of ordinary Portland cement. This magnesia cement only reacted with water after 6 to 8 months, crystals, apparently of magnesium hydroxide, then being discernible. No gel formation could be detected in this period. The dolomite cement prepared from normal dolomite required a temperature of 1600° C. It was but little affected by water, and the magnesia prevented the separation of calcium hydrosilicate crystals. The use of magnesia as a substitute for calcium oxide is thus impracticable, although there is a possibility that ignited magnesite might be added to Portland cement without injurious effect; since although the magnesia combined with silica is hydraulically inactive, caustic magnesia in the form of a very fine powder slowly hardens into monoliths of great stability. The higher the temperature of burning the more slowly does the magnesia harden.—C. A. M.

Mortars; Formation of crystalloids and colloids in the hardening of ——. M. von Glasenapp. Chem.-Zeit., 1914, **38**, 588—589.

IN all cases of the hardening of mortars there is a new formation of crystalloid or colloid monolith elements through the action of water or salt solutions. The hardening of all mortars, with the exception of Portland, Roman and slag cements, depends exclusively upon the formation of crystalloids, whilst in the case of silicate cements (Portland cement, etc.) formation of both crystalloids and colloids occurs. Crystallisation processes alone will produce monoliths equal in hardness and durability to those of Portland cement and even superior (*e.g.* in the case of Sorel's cement) in regard to the proportion of filling materials which can be incorporated. This is opposed to the commonly accepted view that crystallisation tends to disintegration of the mortar. The separation of large crystals of calcium hydroxide in thin sections of Portland cement clinker is cited in support of this view, but such formation of large crystals is not to be observed in the hardening of cement mortars in practice. In addition to calcium hydroxide, hydrosilicates and aluminates also crystallise in the hardening of cement mortars, and even gel-like substances show a similar tendency. The alterations in Portland cement after 3 years are attributed, not to chemical action, but to structural changes, through the slow conversion of colloids into crystalloids. This is supported by the fact that thin sections of old cement mortars (up to 30 years) showed increased transparency to polarised light with their age, and minute crystals could be found. The colloidal substances appear to act, in part, less through their action as a "mineral glue" than through conversion into crystalloids during the hardening process.—C. A. M.

Plaster of Paris; Contribution to the knowledge of —— *from the technical point of view.* G. Gallo. Gaz. chim. ital., 1914, **44**, I., 497—537.

EXPERIMENTS on the conversion of gypsum into plaster and the setting of plaster are described. Ordinary plaster of Paris when freshly prepared consists mainly of soluble anhydrite, but rapidly absorbs moisture and in a few hours is converted into the half-hydrate, $CaSO_4,\frac{1}{2}H_2O$. In calorimetric tests the heat liberated during the setting of plaster corresponded very closely with the heat of formation of the dihydrate, $CaSO_4,2H_2O$, from the half-hydrate. The following scheme for the analysis of plaster of Paris is submitted:—*Hygroscopic moisture* is first determined by drying for 2 hours at 50°—60° C. and then to constant weight over sulphuric acid of sp. gr. 1·4; and the dried material is used in the following tests:—*Soluble anhydrite.* The sample is exposed together with a vessel of water for 12 hours under a bell, then dried over sulphuric acid of sp. gr. 1·4 till of constant weight. The quantity of water absorbed multiplied by 15·11 represents the soluble anhydrite. *Half-hydrate.* The sample is treated with excess of water, dried first at 60°—65° C., then for 24 hours over sulphuric acid of sp. gr. 1·4. The quantity of water absorbed, less that required for converting the soluble anhydrite (previously determined) into the dihydrate, is multiplied by 5·3707 to obtain the quantity of half-hydrate. *Total water* is determined by heating to incipient redness for 10 mins. The difference between the total water and that from the *half-hydrate* represents that from the *dihydrate* (*unburnt gypsum*). The difference between 100 and the sum of the percentages of solubl anhydrite, half-hydrate, and dihydrate, represents th percentage of *natural anhydrite* (or *overburnt plaster*) o foreign impurities. If overburnt plaster be present, th total SO_3 will not correspond with that present as solubl anhydrite, half-hydrate, and dihydrate. A commercia sample of plaster contained: soluble anhydrite, 0; half hydrate, 94·05; dihydrate, 2·21; and overburnt plaster 0·36%. (See also Davis, this J., 1907, 727.)—A. S.

PATENTS.

Stone work and plaster; Method and means for treatin damp porous bodies, especially ——. A. Finkle Moscow. Eng. Pat. 26,079, Nov. 13, 1913.

THE surface is treated with a solution of celluloid i acetone or strong wood spirit, mixed with a solution vegetable tar (*resini pini*) and rosin in ether, to which added white manganese (manganese borate); *e.g.*, aceto 22 kilos., ether 22, celluloid 8, manganese borate 1 *resini pini* 16, and colophony 16. The mixture counte acts the influence of hygroscopic salts, causes moisture evaporate (with the ether and acetone) from the poro body, and forms a waterproof layer on exposure to t air.—F. SODN.

Concrete and the like; Method of mixing ——. L. H. Eichelberger, Baltimore, Md. U.S. Pat. 1,097,084, May 19, 1914; date of Appl., May 21, 1913.

The constituents are fed into a container into which multiple jets of water-laden compressed air are so directed as to maintain a vertical whirling movement of the mass. —F. Sodn.

Distillation of wood, soft coal, lignite, peat and shale, and utilisation of products of distillation for creosoting timber. Eng. Pat. 12,427. *See* IIb.

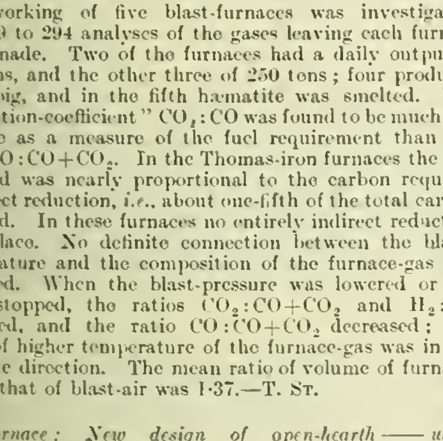
X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Blast-furnaces; The relations between the composition of the throat-gas and the working conditions of ——. M. Levin and J. Wesselmann. Ferrum, 1914, **11**, 261—271.

The working of five blast-furnaces was investigated, from 59 to 294 analyses of the gases leaving each furnace being made. Two of the furnaces had a daily output of 400 tons, and the other three of 250 tons; four produced basic pig, and in the fifth hæmatite was smelted. The "reduction-coefficient" $CO_2:CO$ was found to be much less suitable as a measure of the fuel requirement than the ratio $CO:CO+CO_2$. In the Thomas-iron furnaces the fuel required was nearly proportional to the carbon required for direct reduction, *i.e.*, about one-fifth of the total carbon required. In these furnaces no entirely indirect reduction took place. No definite connection between the blast-temperature and the composition of the furnace-gas was observed. When the blast-pressure was lowered or the blast stopped, the ratios $CO_2:CO+CO_2$ and $H_2:CO$ increased, and the ratio $CO:CO+CO_2$ decreased; the effect of higher temperature of the furnace-gas was in the opposite direction. The mean ratio of volume of furnace-gas to that of blast-air was 1·37.—T. St.

Steel-furnace: New design of open-hearth —— *using producer-gas.* H. F. Miller, jun. Trans. Amer. Inst. Min. Eng., 1914, **45**, 346—354.

The furnace (fig.) has a single air-uptake, A, at the back of the gas-uptake, B, the latter being 6—10 ft. from the bath and of the same width as the port which is made



ow and of small cross-section to promote rapid union of he pre-heated air and gas and produce a short but very t flame well under control throughout the run. A urnace in Sweden similar in principle to the design lescribed was operated for 58 weeks without repairs. —W. E. F. P.

Iron; The γ-transformation of pure —— *and the influence of carbon, silicon, cobalt and copper thereon.* R. Ruer and R. Klesper. Ferrum, 1914, **11**, 257—261.

Pure electrolytic iron containing C 0·009, Cu 0·03 and S 0·001 to 0·002% gave a distinct γ-transformation point at 1401° C. on cooling, and 2 to 3 C. higher on heating. The temperature of the transformation rose with increasing carbon to 1487° C. with C about 0·1%; it then remained constant up to C about 0·4%, above which concentration γ-solid solution crystallised at once. Silicon up to 1·2% lowered the melting point of pure iron very little, and up to 0·2% had no effect on the γ-transformation temperature. Higher proportions up to 1·2%, when the indications had become very indistinct, caused increasingly greater falls in the transformation temperature which had dropped to 1335° C. with Si 1·2%. The γ-transformation curve for alloys of cobalt and carbonless-iron rises in a straight line to 1492° C. at Co 16·5%, and the horizontal of complete equilibrium running from this point meets the melting point curve at Co 25%. With copper-iron alloys the γ-transformation curve rises to 1477° C. at Cu 6·5%, the horizontal from this point meeting the melting point curve at Cu 13%. The results with the cobalt- and copper-alloys are little different from those previously obtained using iron containing C 0·08% (this J., 1913, 1111).—T. St.

Iron-carbon alloys: Observations on the hardness and the electrical resistance of ——. R. Vondráček. Int. Zeits. Metallog., 1914, **6**, 172—182.

Andrew's theory that the hardness of quenched steels is due to the presence of finely divided cementite embedded in a groundmass of austenite and α-iron (this J., 1914, 359) is not in accord with the law that the hardness of such alloys is the mean of the corresponding hardness values of the components, nor with the results of the author's experiments on the electrical conductivity of hardened steels. The total carbon in quenched steels is practically all in solution, and the theory is advanced that the hardness is a particular function of the transformation, and is due to the breaking up of the metal, as it were, during recrystallisation. In this respect there is no essential difference between iron alloys and bronzes. It is deduced from the resistance of hypoeutectoid steels that the ferrite which they contain has an appreciable carbon content, which increases as the total carbon increases. Eutectoid ferrite probably contains from 0·05 to 0·07% C, and with falling temperature the carbon content rises to a maximum of 0·14%.—T. St.

[*Iron.*] *Castings; A study of the annealing process for malleable* ——. O. W. Storey and E. L. Leasman Met. and Chem. Eng., 1914, **12**, 383—389.

Bars of white iron containing C 2·60—2·70, Si 0·65—0·70, S 0·06, P 0·14, and Mn 0·27% were converted into malleable iron under varied conditions. The influence of the several variable factors on the structure of the casting was as follows: *Packing materials.* The ordinary packing materials did not directly affect the structure; with a loose packing, allowing a free circulation of oxidising gases, a carbonless rim was produced, but in a neutral atmosphere the structure of the rim was the same as that of the interior. *Temperature and time of annealing.*—The decomposition of the cementite into ferrite and temper carbon, which determines malleability, required more than 70 hours at 740° C.; it was complete after 18 hours at 985°, and 36 hours at 870° C. The *rate of cooling* after annealing is an important factor: a high rate of cooling results in a steely structure. The critical cooling range is between 830° and 740° C., in which all the carbon separates if the rate is sufficiently low; if so, the rate of cooling below 700° C. has little effect upon the iron. —W. R. S.

Mild-steel; The changes produced in —— *by annealing.* A. Stadeler. Ferrum, 1914, **11**, 271—276.

Sheets of basic Siemens-Martin steel containing C 0·1% were rolled to a thickness of 15·5 mm. and annealed in a tin-plate annealing furnace at the usual temperature for from 1½ hours to 25 days. A slight excess of carbon monoxide was maintained in the furnace and the sheets were protected from the direct action of the flames. After 25 days the thickness of the samples had become reduced to 13·6 mm. Decarburisation was observable at the edges after 3 hours, and was complete in 15 days. Manganese and phosphorus remained constant throughout, and sulphur for eight days, after which it rose slightly. Mechanical tests showed that the strains produced by rolling were removed by annealing at about 860° ± 10° C. for 1½ hours. This produced also maximum strength under impact test. Grain-development began after 3 hours, and was found to be a function of the time of annealing. So long as decarburisation was insignificant the strength under impact test diminished with increasing size of grain.—T. St.

Cementation; Prevention of —— by metallic deposits; diffusion of solid metals. L. Guillet and V. Bernard. Bull. Soc. d'Encour., 1914, **121**, 588—618.

A layer of electrolytically deposited copper, 0·02—0·04 mm. thick, is stated to be the most advantageous coating agent for protecting portions of an article from cementation. Nickel cannot be used instead of copper as it is permeable to carbon monoxide.

Diffusion of solid metals. When the following pairs of metals were heated together, with their surfaces in intimate contact to a temperature below the fusion-point of the lowest-melting metal, diffusion of one metal into another was observed: Fe-Al; Fe-Cu; Cu-Ni; Cu-bronze; Cu-Sn; Cu-brass; Cu-Zn.—W. R. S.

Tool steels; General properties of ——. M. Denis. Rev. Mét., 1914, **11**, 569—669.

The effect of chilling and annealing at various temperatures on the hardness, resiliency, and tenacity, both in the cold and hot state, of a number of tool steels was determined, and also the temperature at which the edge attained its maximum cutting power. Seven carbon steels, three chrome-, two tungsten-, and two nickel-chrome special steels, and six chrome-tungsten and four chrome-tungsten-vanadium high speed steels were used in the tests. Two pages of curves and tables are given for each sample. The resiliency of the carbon steels increased after repeated chilling followed by annealing, being double the original in some cases after 5 successive treatments. After 10 successive treatments, the hardness of carbon steels with more than 0·7% C. ceased to be uniform, whereas the special steels showed uniform, though slightly decreased, hardness. Following, the steels are arranged in order of efficiency, as measured by output (quantity of articles finished, and quantity of turnings removed, before the edge of the tool was blunted:—Cold tests: (1) chrome steels (Cr 2·2—3·4%); (2) hypereutectoid carbon steels (C 0·91—1·26%). Hot tests: (1) special steels; (2) hypereutectoid carbon steels; (3) hypoeutectoid carbon steels. The samples showing the highest cutting efficiency at higher temperatures were: (1) tungsten steel (W 3·53%); (2) hypereutectoid carbon steels (C 0·95—1·26%); (3) chrome steel (Cr 3·40%).—W. R. S.

Iron and steel; Direct determination of carbon in ——. W. D. Brown. Met. and Chem. Eng., 1914, **12**, 390.

In the process described the boat containing the metal is placed in the cold part of a silica tube, which is then closed with a two-hole stopper fitted with a nichrome plunger rod. After the air has been displaced by oxygen the boat is pushed into the hottest part of the tube by the plunger; oxygen is passed at the rate of 400 c.c. per minute. The tube contains a layer of loosely packed ignited asbestos which acts as a catalyser. Under these conditions, with an initial temperature of about 980° C., a temperature of about 1650° C. is obtained momentarily and complete combustion takes place as fast as the oxygen is supplied. The determination may be completed in 10 minutes.—W. R. S.

Carbon in steel and iron by the barium carbonate titration method; Determination of ——. J. R. Cain. J. Ind. Eng. Chem., 1914, **6**, 465—468.

Carbon in iron and steel may be rapidly determined by burning it to carbon dioxide, absorbing the latter in barium hydroxide solution, filtering off the barium carbonate, with exclusion of air, on a filter composed of a mat of asbestos and a layer of quartz grains of different sizes (50% passing a 20-mesh, and the remainder passing a 10-mesh and retained by a 20-mesh sieve), washing with water free from carbon dioxide (150 c.c. are usually sufficient), dissolving in excess of $N/10$ hydrochloric acid, and titrating the excess of acid with $N/10$ sodium hydroxide, using methyl orange as indicator. The usual purifying train connected with the combustion tube may be dispensed with, an 8-bulb Meyer tube containing the barium hydroxide solution being directly attached. The oxygen should not be passed too rapidly. In tests with U.S. Bureau of Standards analysed irons and steels, the mean error in eight determinations was —0·000056 grm. —A. S.

[Silver ores.] Desulphurising process at the Nipissing mill, Ontario. Min. and Eng. World, June 6, 1914, 1070.

A wet desulphurising process in which the slime pulp is mixed with caustic soda solution and passed through a revolving tube mill in which there are a number of aluminium ingots. A further treatment is given in a tank lined with aluminium plates, in which the pulp is slowly agitated for 24—36 hours. The slime is then dewatered in a Butters filter plant, and cyanided for 48 hours. The silver is obtained in a spongy metallic state, readily amenable to the cyanide treatment, resulting in improved extraction after shorter contact with the cyanide liquor. (See also Eng. Pat. 18,660 of 1912; this J., 1913, 915.) —W. R. S.

Silver bar; Fineness of the 800 standard ——. O. Yamagata. J. Coll. Eng. Imp. Univ., Tokio, 1914, **5**, 191—212.

The silver bars used for 50-sen coinage at the Imperial Mint, Osaka, are 584 mm. long, 49·2 wide and 11·88 thick; they are cast "on end," and, after removal of the top portion (2—3 cm.), rolled down to "fillets," 56·6 mm. wide and 1·73 thick, from which the "blanks" are cut. A number of fillets (some from whole bars, *i.e.*, as cast) were cut lengthwise into equal strips and then transversely at equidistant points, each portion being assayed separately. It was found that throughout the length of the fillet the fineness was highest along the middle and gradually decreased towards both sides. The portion
representing the top and bottom ends of the bar wer
respectively richer and poorer in silver than the bulk. th
composition being irregular at the former, but unifor
at the latter, part; for this reason, at least 2 cm. shoul
be cut off the top of the bar before rolling, and it woul
also be advisable to reject a small portion of the botto
of the finished fillet. At all other parts of the fillet th
average fineness was practically uniform and in agreemen
with the pot assay. The fineness of a bar cast from th
very bottom of a pot (*i.e.* the residue of a melting) wa
irregular and considerably higher than the correspondin
pot assay. Accurate sampling of the normal bar by th
method of cutting assay-pieces is regarded as practicall
impossible. A 50-sen coin was sampled by taking thr
equal, circular punchings, one from each angle of a
equilateral triangle described in a concentric circle havi
five-sevenths of the coin's diameter; this method ga
better results than that involving a central punching
the coin. The average fineness of the alloy at each sta
of minting was as follows:—pot assay 798·9, fillet 799·
"scissel" (the portion of the fillet remaining after t
"blanks" have been cut out) 798·5, blank 799·2, co
799·6.—W. E. F. P.

Copper-nickel ores; Chloridising the Sudbury ——. A.
Carpenter. Eng. and Min. J., 1914, **97**, 1085—1089.

In tests made on the applicability of the Longma
Henderson process to the treatment of cinders fr

Sudbury copper-nickel ores, in order to leach out the copper and obtain a residue suitable for direct smelting to ferro-nickel pig or steel, the most favourable conditions were found to be as follows: the final temperature in roasting must be high enough to decompose the nickel sulphate; the chloridising roast must be conducted at 370°—425° C. to prevent the formation of nickel chloride and its volatilisation. The sulphur content should be reduced to 1½ times the copper content, and if more is removed by roasting, a suitable amount of pyrites is added previous to chloridising. Low-grade copper-nickel matte was also treated successfully by this method. —W. R. S.

Spelter; Production of —— in Upper Silesia. A. Rzehulka. Z. angew. Chem., 1914, **27**, 327—328.

The production of spelter in Silesia dates back to 1809, the total production up to 1913 inclusive being 5,047,421 tons. Oxidised ores were treated exclusively until about 1860; since then blende also has been worked, and is now by far the most important ore. Belgian retorts have lately displaced the large Silesian muffles, although the latter were more advantageous in the treatment of low-grade ores.—W. R. S.

Zinc blendes; Treatment of roasted —— for the decomposition of zinc ferrites previous to distillation. V. Lindt. Metall u. Erz, 1914, **11**, 405—408.

Zinc ferrites formed in the roasting of blende may be decomposed by reduction with producer gas. In a laboratory experiment in which a sample of roasted blende was treated with coal gas, the content of zinc present in the form of combined ZnO fell from 6·4 to 2·5% after 40 minutes' heating.—W. R. S.

Aluminium; Nickel-plated ——. E. Tassilly. Rev. Mét., 1914, **11**, 670—673.

An adherent nickel deposit on aluminium is easily obtained by Canac's process (Eng. Pat. 24,019 of 1911; this J., 1912, 394). The aluminium is treated with boiling potassium carbonate solution, then brushed with milk of lime, and immersed for a few minutes in a 0·2% solution of potassium cyanide, and in a solution of 1 grm. of iron in 1 litre of hydrochloric acid (1 : 1) until it acquires a moiré appearance. The nickel is deposited as usual, *e.g.*, from a bath containing 50 grms. of nickel chloride and 20 grms. of boric acid per litre. The addition of iron to the last preparing solution is essential: a minute deposit of iron (0·25—0·5 grm. per sq. metre) was found on the aluminium, and microscopical examination of the surface showed a cellular structure. The iron appears to form a network of microscopic galvanic couples, which produces a rough surface. This accounts for the strong adhesion of the deposit, which cannot be detached without also tearing off aluminium particles.—W. R. S.

Arsenic; The melting point of ——. W. Heike. Int. Zeits. Metallog., 1914, **6**, 168—171.

Heating and cooling curves of arsenic contained in an exhausted porcelain vessel packed in sand in an iron bomb, gave a melting point of 830° C. No other thermal effects were observed between this temperature and 50° C. The arsenic after having been melted was steel-ray to lead-gray in colour; it was very brittle and broke asily with a brilliant fracture; the hardness on Mohs' cale was 3½—4.—T. St.

Resistance of platinum vessels to hot nitric acid. Baxter and Grover. *See* VII.

Determination of nickel by dimethylglyoxime. O. Brunck. *See* XXIII.

Patents.

on; Treatment of ——. A. V. Dismore, Slough, Bucks. Eng. Pat. 4292, Feb. 19, 1913.

E iron is made the cathode in an electrolyte composed "nickel salts" 1 lb., common salt 1¼ lb., platinum bichloride 3·75 grains, and water 1 gallon, the anode consisting of nickel and carbon placed respectively on opposite sides of the iron. A low-tension current is first passed through the bath, and then a high-tension current (up to 1000 volts), which automatically cuts out the first current, is suddenly switched in. After a suitable time the iron is cleaned by immersion in boiling water. The treatment is stated to produce enhanced malleability, ductility, and tensile strength.—T. St.

Cast-iron; Production of ——. A. W. Gregory, London. Eng. Pat. 6530, March 17, 1913.

Cast iron suitable for conversion into malleable castings is made by melting steel or wrought iron scrap with carbonaceous and silicon-bearing materials. Manganese is removed by the addition of a sulphur-bearing material, preferably an inferior coke, high in sulphur, whereby manganese sulphide is formed and passes into the slag. —T. St.

Steel manufacture. The British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 11,370, May 15, 1913.

The hysteresis action of silicon steel is reduced by 10—30% by heating it for 2—5 hours at 1100°—1325° C. in a reducing atmosphere (hydrogen) or in a vacuum (2—2·5 mm. of mercury).—W. E. F. P.

[*Steel*]. *Metallic articles such as gun-barrels, and turbine blades, which require great power of resistance to corrosion, that is against the influences of moist air, water, sea-water, and the like (not acids).* C. Pasel, Essen (Ruhr), Germany. Eng. Pat. 13,414, June 10, 1913. Under Int. Conv., Oct. 17, 1912.

The steel alloys used contain Cr 7 to 25, Ni 20 to 0·5, and C up to 1%, and when the articles are required to be non-magnetic, the chromium should be not less than 8%. Those of the alloys with a Brinell hardness above 380 are made soft and workable by heating to between 500° C. and the critical point (720°—780° C.) and cooling. Preliminary heating to 800°—1000° C. imparts great strength and toughness, and subsequent heating to 800°—900° C. rehardens the alloys. Those of the alloys with a Brinell hardness below 350 are made very tough and non-magnetic, by heating to 1100°—1200° C. and cooling rapidly.—T. St.

[*Steel.*] *Metal articles such as vessels, tubes, and parts of machinery, which require great power of resistance to attack by acids and great strength.* C. Pasel, Essen (Ruhr), Germany. Eng. Pat. 13,415, June 10, 1913. Under Int. Conv., Dec. 20, 1912.

A steel alloy containing Cr 15 to 40, Ni 20 to 4, and C up to 1%, is very resistant to the action of acids, especially nitric acid, and possesses great strength. After being heated to 1100°—1200° C., the cooled alloy is very tough and may be worked up into sheets, tubes, etc., without difficulty.—T. St.

[*Iron and copper.*] *Metal and carbon; Manufacturing agglomerates of reduced ——, termed in particular "ferro-carbonite" and "cupro-carbonite."* J. G. Aarts, Dongen, Holland. Eng. Pat. 17,613, July 31, 1913. Under Int. Conv., Aug. 1, 1912.

A mixture of the (iron or copper) ore with powdered coal is "carbonised" in a vertical retort the upper part of which is heated (attaining a temperature of about 1200° C. at the hottest zone) while the lower end is immersed in water. The red-hot agglomerate is continuously discharged into the latter, the steam generated passing upwards through the charge and producing hydrogen and carbon monoxide by which the ore in the upper zones of the retort is reduced. The proportions of ore and coal are adjusted so that the agglomerate contains sufficient fuel for subsequent fusion in the cupola.—W. E. F. P.

[Iron] Ores; Process of reducing ——. H. C. Alford, St. Louis, Mo. U.S. Pat. 1,097,156, May 19, 1914; date of Appl., Sept. 1, 1911.

Powdered iron oxide ore is preheated, then mixed with excess of carbon and heated to about 1000° F. (538° C.) in order to effect reduction without fusion. Two horizontal cylinders, one above the other, and geared to rotate together in opposite directions, are mounted in a heating-chamber. They are connected within the chamber by a vertical end-piece, fitted with an inclined side-pipe through which coal is introduced by means of a screw conveyor. Within each cylinder is a fixed worm or screw so that, on rotation, the charge is propelled through the apparatus continuously. The ore is preheated in the upper and reduced in the lower cylinder.—W. E. F. P.

Armour-plate; Method of treating ——. S. S. Wales, Munhall, Assignor to Carnegie Steel Co., Pittsburgh, Pa. U.S. Pat. 1,097,572, May 19, 1914; date of Appl. Nov. 15, 1906.

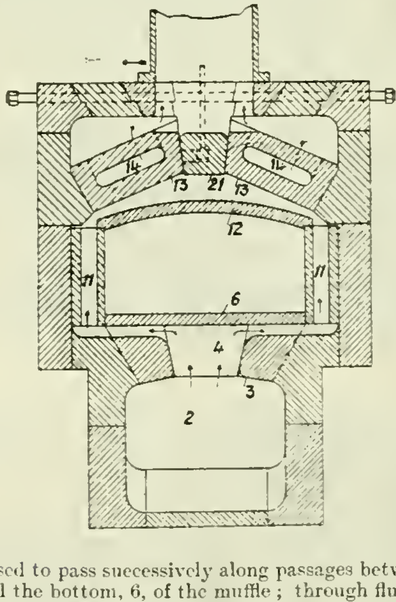
The forged plate is successively heated to 700° C., re-forged, heated to 875° C., quenched, heated to 775° C., air-cooled, machined, re-heated to rather less than 775° C., formed, annealed, machined, and water-hardened. One surface of the hardened plate may be softened by heating and air-cooling, the opposite side being sprayed during the operation to prevent equalisation of the temperature through the material.—W. E. F. P.

Metals; Anti-friction ——. C. Billington, Stoke-on-Trent. Eng. Pat. 11,138, May 13, 1913.

Sn-Sb-Cu-alloys, with or without Pb and containing Ni 0·1—5·0%. The following percentage compositions are given as examples:—(1) Sn 84, Sb 9, Cu 6, Ni 1; (2) Sn 74, Sb 9·75, Pb 10, Cu 5, Ni 1·25.—W. E. F. P.

Furnaces; Muffle and similar ——. August's Muffle Furnaces Ltd. and J. R. C. August, Halifax. Eng. Pat. 11,386, May 15, 1913.

A furnace in which the gases issuing from the fire-box, 2 (see fig.), through a series of slots, 4, arranged along the middle of the slab, 3, forming the roof of the fire-box, are caused to pass successively along passages between this slab and the bottom, 6, of the muffle; through flue bricks, 11, forming the sides; over the top, 12, and towards the front of the muffle, beneath removable, wedge-shaped slabs or blocks, 13, supported along the middle of the structure by a keystone, 21, secured to the upper portion of the apparatus; through internal, horizontal passages, 14, in the slabs, 13, towards the back of the furnace; above the slabs, 13, towards the front, and thence to the chimney.—W. E. F. P.



[Lead and zinc.] Ores; Separation of metallic sulphide ——. F. J. Lyster, Broken Hill, N.S.W. Eng. Pat. 11,939, May 22, 1913.

The ore is treated twice by froth-flotation at atmospheric temperature: first in a neutral or alkaline solution to produce a concentrate relatively rich in galena; and then in water to produce a concentrate relatively rich in blende. The medium in which the first separation is effected may be a natural "mine water" or a prepared solution containing one or more of the following compounds: chloride, hydroxide, nitrate or sulphate of calcium, magnesium, sodium or potassium; chloride of barium, carbonate or bicarbonate of sodium, sulphate of manganese, zinc, iron or aluminium.—W. E. F. P.

Sulphide ores; Flotation process for the concentration of —— by means of oil and nascent gases. Tellus A.-G. für Bergbau und Hüttenindustrie. Ger. Pat. 273,266, March 1, 1913.

The finely ground ore is mixed with water to which sodium sulphide or carbonate is added, and with oil, and the pulp is distributed uniformly over the surface of a body of water to which acid is supplied below the surface. The hydrogen sulphide or carbon dioxide evolved adheres to the oiled sulphide particles and carries them over the edge of the receptacle, whilst the particles of gangue sink to the bottom. The proportions of sodium sulphide or carbonate and of acid may be adjusted so as to give a neutral effluent.—A. S.

Silver-lead-zinc ores; Treatment of —— by smelting with zinc chloride or its double salts. E. Langguth. Ger. Pat. 273,483, April 5, 1913.

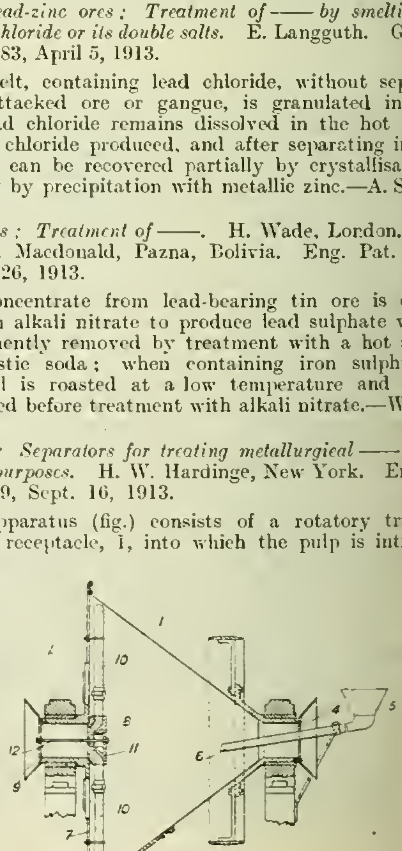
The melt, containing lead chloride, without separation of unattacked ore or gangue, is granulated in water. The lead chloride remains dissolved in the hot solution of zinc chloride produced, and after separating insoluble matter, can be recovered partially by crystallisation, or entirely by precipitation with metallic zinc.—A. S.

Tin ores; Treatment of ——. H. Wade, London. From J. B. Macdonald, Pazna, Bolivia. Eng. Pat. 12,267, May 26, 1913.

The concentrate from lead-bearing tin ore is calcine with an alkali nitrate to produce lead sulphate which i subsequently removed by treatment with a hot solutio of caustic soda; when containing iron sulphide th material is roasted at a low temperature and re-concentrated before treatment with alkali nitrate.—W.E.F.P

Slimes; Separators for treating metallurgical —— and fo like purposes. H. W. Hardinge, New York. Eng. Pat 20,919, Sept. 16, 1913.

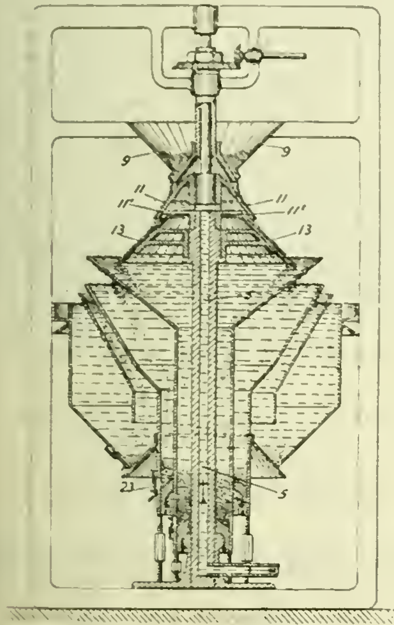
The apparatus (fig.) consists of a rotatory truncate conical receptacle, 1, into which the pulp is introduce through the smaller end, 4, from a hopper, 5, by a pipe, and discharged in part from a central opening 8, in t



larger end, 7. The opening, 8, is provided externally with a funnel, 9, and internally with a series of open, radial pipes, 10, which rotate with the receptacle and are carried at their converging ends in a block, 11, clamped against the side of the vessel by means of a rod, 12. During rotation the heavier particles of the material gravitate to the larger end of the receptacle, are taken up by the pipes, 10, and discharged through the funnel, 9; while the lighter particles are discharged through the opening, 4, the level for discharge being preferably such that the receptacle will never be quite half full.—W. E. F. P.

Ore: Apparatus for washing ——. H. A. Brackelsberg, Hagen, Germany. Eng. Pat. 13,987, June 17, 1913.

The finely powdered, dry ore is allowed to fall freely from a hopper, 9 (fig.), on to a distributing cone, 11, and thence to a spreader cone, 13, upon the surface of hich is maintained a continuous stream of water, supplied through a pipe, 5, to the interior of the cone, 11, rom which it is delivered, through openings, 11′, under steady pressure by reason of the air cushion in the pper part of the cone. Beneath the spreader cone, a eries of funnel-shaped vessels, filled with water and velled by means of screws and ball-headed bearings t the base of the apparatus, are disposed concentrically, shown, classification of the ore pulp being effected means of the successive overflows, and clear water ischarged peripherally from the outermost vessel. —W. E. F. P.



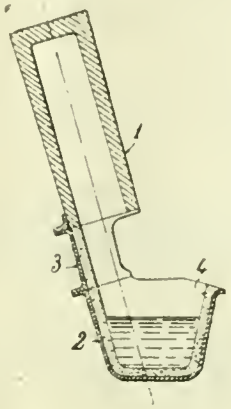
ungsten.] *Wire; Process of drawing* ——, *and apparatus r same.* H. Schinnerling, Reinickendorf-Ost, Germany, Assignor to General Electric Co. U.S. Pat. 1,096,866, May 19, 1914; date of Appl., April 16, 1913.

HE (tungsten) wire is drawn through a die immersed in bath of lubricant (oil) at 300°—400° C.—W. E. F. P.

ires; Method of pointing —— *for wire-drawing.* Wolframlampen-A.-G. Ger. Pat. 272,731, May 7, 1912.

HE end of the wire is treated with a fused chlorinating sulphurising bath of inorganic chlorine or sulphur mpounds. For example the wire may be dipped into fused timony pentachloride or used as anode in the electrosis of fused calcium chloride.—A. S.

Metals and alloys; Process of casting ingots of ——, *and apparatus therefor.* P. H. G. Durville, Paris. Eng. Pat. 23,719, Oct. 20, 1913. Under Int. Conv., Nov. 21, 1912.



The apparatus (fig.) consists of a mould, 1, having an extension, 3, to which a reservoir, 2, is attached, the latter and extension being lined with refractory material, 4. The reservoir is charged and the apparatus slowly inverted so as to fill the mould without agitating the molten metal.—W. E. F. P.

[*Zinc from brass.*] *Volatilised matter; Process of separating and recovering* ——. G. Mellen, East Orange, N.J. U.S. Pat. 1,097,135, May 19, 1914; date of Appl., Dec. 19, 1912.

Molten brass is caused to flow down a series of steps within a vertical furnace and exposed to the action of a gaseous stream traversing the furnace in the opposite direction. Volatilised zinc oxide is collected at the top, and the molten residue at the bottom, of the apparatus. —W. E. F. P.

Metals and oxides; Process for separating and recovering —— *from molten slags and other products.* A. Desgraz. Ger. Pat. 273,047, June 13, 1913.

The metals or oxides are separated from the slag or the like by treatment with reducing agents, with or without other additions, in a reverberatory furnace so arranged that the charge moves with decreasing velocity towards the hottest part of the furnace, whilst simultaneously its surface increases. The furnace is divided into several compartments arranged in steps, so that as the surface of the charge becomes larger its depth becomes less. As the charge moves towards the hottest part of the furnace, and the desired metals are separated from the slag, the latter becomes lighter and, separating from the heavier portion, becomes exposed in increasing degree to the flame.—A. S.

Platinum; Process for separating —— *from iridium and other metals.* Verein Chemischer Fabriken in Mannheim. Ger. Pat. 273,178, March 28, 1913.

The mixture of metals is treated with chlorine above 585° C. until the iridium is completely converted into chloride. A portion of the platinum is converted into chloride and volatilised, but most of it is unattacked and is separated from the non-volatile iridium trichloride by elutriation or by dissolving in *aqua regia*.—A. S.

Chemical reactions sensitive to air or oxygen [e.g., reduction of easily oxidisable metals]; Process for carrying out —— *in an inert atmosphere.* O. Knöfler und Co. Ger. Pat. 273,218, Oct. 18, 1912.

A solid or liquid substance, which on heating gives off non-oxidising vapours, is added to the reaction mixture. Formaldehyde, for example, is decomposed into carbon monoxide and hydrogen at 500° C., and easily oxidisable metals such as thorium, zirconium, cerium, titanium, and vanadium may be obtained from their compounds by heating with metallic calcium in presence of 5—10% of trioxymethylene. Ammonium compounds and hydrocarbons may be used in a similar manner to produce a non-oxidising atmosphere.—A. S.

Metals; Furnace for obtaining easily oxidisable ——. A. Zavelberg. Ger. Pat. 273,308, Aug. 7, 1913. Addition to Ger. Pat. 226,257.

In carrying out the process described in the chief patent (this J., 1910, 1460), in order to maintain the inner portions of the walls of the reaction chamber at a uniform temperature and restrict the cooling to the outer surface, heating flues are constructed in the walls.—A. S.

Iron and manganese ores, pyrites cinder, blende, etc.; Process for roasting and sintering ores and metallurgical products, e.g. ——. W. Buddeus. Ger. Pat. 273,277, Jan. 16, 1913.

Thin metal tubes, spaced apart, are placed in the sintering chamber and the ore is fed in around the tubes. The fuel is then introduced into the spaces enclosed by the tubes and the latter are withdrawn. Sintering is effected by a blast of air forced through the charge in a direction parallel to the columns of fuel.—A. S.

Aluminium; Production of a coating on —— *resisting the action of sea-water and concentrated acids or alkalis.* Z. D'Amico. Ger. Pat. 273,292, Dec. 10, 1912. Addition to Ger. Pat. 248,857 (this J., 1912, 824).

The aluminium is treated first with a solution of caustic alkali and then, without removing the aluminate formed and the excess of alkali, with a solution containing potassium-iron tartrate and cupric, ammonium, ferric, zinc and stannic chlorides. The coated metal is washed with lime water and warm water, heated, and treated with a mixture of oils and balsams as described previously (*loc. cit.*). The cupric chloride may be replaced by copper sulphate, and finely powdered calcium carbonate or a caustic alkali may be added to the solution of metallic salts. —A. S.

Aluminium; Process for protecting and decorating ——. J. Tronel. Ger. Pat. 273,498, May 21, 1912.

The metal is first sprayed with a mixture of an alkaline cleansing agent, ammoniacal nickel sulphate solution, precipitated silica, and small quantities of zinc and tin compounds, then washed with water, dried, treated with a solution of rubber, gutta-percha, and nitrated castor oil or its substitutes, again dried, at a high temperature, and then treated with a solution of nitrocellulose, celluloid (inflammable with difficulty), fatty acids, and gum-like substances produced by the transformation of lactic acid in presence of organic and inorganic salts. An elastic transparent coating is obtained which is not broken even when the metal is worked mechanically.—A. S.

Electrolytic furnaces for the production of light metals. G. B. Ellis, London. From Sodium Process Co., New York. Eng. Pat. 29,418, Dec. 20, 1913.

See U.S. Pat. 1,092,178 of 1914; this J., 1914, 555.—T.F.B.

Treatment of phosphate slag for agricultural purposes. Eng. Pat. 922. *See* XVI.

XI.—ELECTRO-CHEMISTRY.

Mercurous sulphate; Commercial preparation of —— *for normal cells.* E. Warburg. Z. Elektrochem., 1914, 20, 345

Ordinary commercial mercurous sulphate is not suitable for the preparation of Weston normal cells, but there is now on the market material prepared under the advice of, and tested by, the Physikalisch-technische Reichsanstalt specially for this purpose. The salt is contained in sealed and stamped vessels under saturated cadmium sulphate solution. It is prepared by von Steinwehr's precipitation method (Z. Instrumentenkunde, 1905, **25**, 205: to obtain preparations composed of crystals of uniform size, and hence having the same solubility, and giving, in the cell, the same E.M.F., one of the reacting solutions is heated to 80°—100° C., and the other is added, drop by drop, with constant agitation; the very small crystals are removed from the product by elutriation).—W. H. P.

Anodic oxidation of ammonia in alkaline solution in presence of silver salts. Scagliarini. *See* VII.

Reduction of disodium phosphate by alternating electric currents. Wenger and Heinen. *See* VII.

Patents.

Refractory materials fusible only at high temperatures; Fusion of ——. E. Podszus. Fr. Pat. 465,604, Dec. 2, 1913. Under Int. Conv., Dec. 2, 1912.

The process is designed for the fusion of oxides of zirconium thorium, aluminium, etc., which is impossible in an ordinary electric arc on account of their combination of low conductivity and high melting-point. An inner chamber of refractory clay, surrounded by sheet iron, is provided with electrodes of which the upper can be manipulated in order to adjust their distance apart. The current is started with the electrodes close together, and the lower one, packed in the badly conducting material —which is in a granular condition and not powdered lest it should be scattered and thus extinguish the arc— attains a high temperature and melts the surrounding particles which percolate to the bottom and in the melted condition are sufficiently good conductors to take the place of the lower electrode, so that the arc plays on the surface of the melt. Volatilised fumes raise the conductivity of the atmosphere, and by raising the upper electrode, an arc of 20 cm. length is obtained at a tension of 22 volts. Electrodes of composition resembling the materia to be fused may be used.—H. H. S.

Process for treating zinc sulphate liquors. Eng. Pat. 2952 *See* VII.

Electrolysis and treatment of [zinc] sulphate liquors. Eng Pat. 11,634. *See* VII.

Electrostatic separators for treating inflammable or explosi materials. Eng. Pat. 26,802. *See* I.

Cathodic production of hydrogen peroxide in electrolyt containing oxygen or an oxygen-containing gas. Ge Pat. 273,269. *See* VII.

XII.—FATS; OILS; WAXES.

Fats; Preparation of optically active ——. *I. Synthes of optically active halogenhydrins.* E. Abderhald and E. Eichwald. Ber., 1914, **47**, 1856—1866.

Allylamine was neutralised with hydrobromic acid a brominated, and from the resulting dibromopropylami hydrobromide, $CH_2Br.CHBr.CH_2.NH_2.HBr$, the *d*-tartra (m.pt. 131° C.) was obtained by treatment with *d*-silv tartrate. On fractional crystallisation crystals wi $[\alpha]_D = +25{\cdot}59°$ and $+31{\cdot}17°$ were obtained. By treati the *d*-tartrate with sodium nitrite, *d*-dibromhydr ($[\alpha]_D = +6{\cdot}25°$) separated, whilst the *l*-product could separated from the mother liquor. The optically acti dibromhydrin was transformed by alcoholic potassi hydroxide into *d*- and *l*-epibromhydrins, the former havi $[\alpha]_D = +6{\cdot}45°$. Introduction of caproic acid into t hydroxyl group produced a pronounced increase in t optical rotation. Attempts to remove both bromine ato from the dibromhydrin were unsuccessful.—C. A. M.

Linseed and petroleum oils; Iodine value of ——. W Smith and J. B. Tuttle. U.S. Bureau of Standar Technologic paper No. 37. J. Franklin Inst., 19 **177**, 687.

The iodine values of raw linseed oils determined with Han solution, were concordant for amounts up to 0·25 grm., decreased with the increase in weight above that limit. With burnt oils, an increase in the degree of burning reduced the limit of agreement with different weights of oil. With petroleum oils the iodine values were concordant for quantities of 0·6 grm. and upwards, the maximum absorption being obtained in about 10 mins. Oils with the highest iodine values did not require the largest excess of iodine to obtain the maximum absorption. The influence of temperature was greater upon the iodine value of burnt than of raw or boiled linseed oils.—C. A. M.

Acetyl value of oils, fats, etc.; Determination of the ——. E. B. Holland. J. Ind. Eng. Chem., 1914, **6**, 482—486.

The author recommends determination of the saponification value of the fat before and after acetylation, the difference being the acetyl value and representing the number of mgrms. of potassium hydroxide required for the saponification of the acetyl fixed by 1 grm. of oil on acetylation. 5 grms. of fat are heated with 10 c.c. of acetic anhydride for 1—1½ hours under a reflux condenser, and the acetylated fat with addition of sufficient pure ceresin, washed and separated as in the determination of the insoluble acids, and its saponification value determined. If the original fat contains free soluble acids, a correction must be applied.—A. S.

Hardened oils. E. Mellana. Annali Chim. Appl., 1914, **1**, 381—387.

Samples of cottonseed, soya bean, kapok seed, whale and sperm oils were hardened by hydrogenation in presence of reduced nickel, and the characters of the products compared with those of the original oils. Samples of "talgol" (from whale oil), "candelite" (from whale oil) and "coryphol" (from castor oil) were also examined. The results are shown in the following table:—

	M.pt.	M. pt. of fatty acids.	Solidif. pt. of fatty acids.	Saponif. value.	Iodine value.	Acetyl value.	Refractometer reading at 60° C.
	°C.	°C.	°C.				
lardened :							
Cottonseed oil	59	57	50·3	192·3	41	—	—
Soya bean oil	68	66	61·2	190·9	15·2	—	—

'he oils after hydrogenation responded to the general olour reactions for seed or marine animal oils respectively, ut less distinctly and with more or less modified colour ffects. Halphen's and Milliaus' reactions for cottonseed nd kapok seed oils usually gave negative results with the ardened oils. All of the samples contained traces of ickel. (See also this J., 1912, 996; 1913, 201, 370, 665.) —A. S.

oaps; Contribution to the knowledge of ——. The gelatinisation of solutions of potassium laurate and oleate. and of mixtures of the two. J. Kurzmann. Kolloidchem. Beihefte, 1914, **5**, 427—484.

o obtain information regarding the property of forming jelly which is possessed by solutions of potassium laurate id of mixtures of which it is a large constituent, especially presence of an electrolyte, the author determined the scosity and electrical conductivity of solutions of this lt and of potassium oleate and of mixtures of the two. ıe determinations were made under very varied contions of temperature and concentration and in the esence of different electrolytes, the viscometer used ing specially designed to permit of determinations ing carried out with highly viscous solutions. The scosity of potassium oleate at first increased gradually th increasing concentration, but with solutions of ½ grm.-ol. per litre and upwards the rise was extremely rapid, the viscosity attaining a very high value, even exceeding that recorded for potassium palmitate by Farrow (this J., 1912, 289). Solutions of the oleate of 0·4*N* strength and less exhibited a high temperature coefficient of viscosity. The rise in the viscosity of potassium laurate solutions was very moderate and gradual, and even with the more concentrated solutions the temperature coefficients were of a lower order of magnitude than those of the oleate. The behaviour of potassium myristate gave results intermediate between those obtained with the laurate and oleate though it most resembled the laurate. The behaviour of the potassium soap obtained from palm-kernel oil, the chief constituent of which is potassium laurate, was very similar to that of the pure laurate. The addition of small proportions of potassium laurate to potassium oleate slightly raised the viscosity at 90° C. and considerably reduced it at 20° C., the temperature coefficient of the viscosity of such mixtures being considerably less than that of pure potassium oleate solutions, especially at fairly high concentrations. The addition of potassium hydroxide to a neutral soap solution decreased the viscosity at low concentration but at higher concentration increased it. To obtain the same effects with potassium oleate solutions as with potassium laurate solutions much smaller quantities of the hydroxide were required and the action of the hydroxide was greater the more concentrated the oleate solution. The addition oven of small quantities of potassium laurate to the oleate caused the properties of mixtures to approximate to those of the pure laurate. The action of the hydroxide varied with the temperature in such a way, that concentrations which reduced the viscosity at high temperatures increased it at lower temperatures. The critical concentration of the potassium hydroxide at which the viscosity was increased may be called the "gelatinising" concentration since at this point cooling the solution brought about the formation of a jelly. The temperature coefficient of the viscosity was decreased by the addition of small quantities of potassium hydroxide and increased by the addition of larger quantities before the "critical concentration of gelatinisation" was reached. The temperature coefficient of the oleate was much higher than that of the laurate. The viscosity of the potassium soap obtained from palm-kernel oil was much less affected by potassium carbonate than by potassium hydroxide when the effect of solutions of equivalent concentration was compared, but when equimolecular solutions were compared the effect of potassium carbonate was of the same order as that of potassium hydroxide. This indicates that the effect is due to the anion, the divalent carbonate ion being more active than the monovalent hydroxyl ion. It is not yet possible to explain the peculiar course of the viscosity curves which represent the effect of increased additions of potassium hydroxide. The peculiar minimum on the viscosity curves observed on adding increasing quantities of potassium hydroxide cannot be ascribed to the influence of electrolytic or hydrolytic dissociation of the soap since, on the one hand, similar effects may be observed with potassium hydroxide and potassium chloride (Goldschmidt and Wiessmann, this J., 1912, 593) and on the other hand, colloids which cannot dissociate exhibit similar behaviour on the addition of an electrolyte (Woudstra, Kolloid-Zeitschrift, 8, 80). The properties exhibited by the potash soaps were distinctly different from those of the albumins in which the formation of albumin ions or alkali salt seems to be associated with an alteration in viscosity. This change in the viscosity is an increase and not a decrease and is similar to the behaviour of ammonia soaps on the addition of ammonia (this J., 1913, 201). The curves of the molar conductivities were abnormal for all the soaps examined and were similar to those already determined for the soda soaps. An addition of potassium hydroxide or potassium carbonate lowered the conductivity of all the soaps examined, the conductivity of the mixture tending to become lower than that of the pure electrolyte which had been added. The temperature coefficient of the conductivity of the mixtures fell regularly from the high values characteristic of the neutral soaps to those already known for pure potassium hydroxide solution. The conductivity of a mixture of potassium laurate and potassium oleate was higher than the sum of the conductivities of its components and this increase in the conductivity was more pronounced at low than at higher temperatures. When applied to technical operations the results of this investigation show that a calculation to determine the behaviour of a mixture of fats cannot be made additively from a knowledge of the properties of its constituents and that complicated reciprocal influences operate in mixtures of soaps of different molecular weights.—J. A.

Soap; Determination of the fatty acid content of ——. A. A. Besson. Chem.-Zeit., 1914, **38**, 645—647, 686—687.

The author compared the efficiency of petroleum spirit and ether as solvents for fatty acids. The latter is to be preferred on account of the greater ease with which it can be vaporised without leaving any appreciable residue. The short period of heating required to remove this solvent also reduces the loss of volatile fatty acids to a minimum, this loss always being considerable when even carefully distilled petroleum spirit boiling below 65° C. is employed. Further, ether is a better solvent for lactones and hydroxyfatty acids, which occur in many fats (sulphur olive oil for instance) used extensively for soap making. The solubility of water in ether is not objectionable as this is considerably reduced by the presence in the water solution of the salt formed when the soap is decomposed with an acid.—J. A.

Talc as a lubricant. F. Thalberg. Chem.-Zeit., 1914, **38**, 711—712.

Talc does not behave like graphite on treatment with tannin solutions, but may be brought into a finer molecular state by being heated with ammonium carbonate, or by treatment for several hours with a current of dry ammonia. Afterwards the talc is dried *in vacuo*, since heating causes the particles to agglomerate again. The treated material forms fine suspensions in water which are very difficult to filter, and subsides exceedingly slowly in lubricating oils of medium density. When once suspended in a neutral oil no subsidence of the talc occurs on heating. The change in the character of the talc is attributed to the absorption of a minute quantity of ammonia. From 40 to 60% of ordinary talc may be introduced into heavy mineral oil provided that the oil be added to the talc and not the reverse.—C. A. M.

Deodorisation of naphthenic acids. Schmitz. *See* IIa.

Treatment of grain [in the distillery] for the recovery of oil, utilising enzymes. Vasseux. *See* XVIII.

Patents.

Catalysing agents [for hydrogenation of oils]; Manufacture of ——. W. Fuchs, Vienna. Eng. Pat. 11,542, May 17, 1913. Under Int. Conv., May 18, 1912.

To reduce unsaturated liquid fatty acids and their glycerides, carbonates of base metals easily dissociated, such as nickel carbonate, are heated to 230° C. beneath the surface of the oil, and subjected to the action of hydrogen under pressure. When metallic nickel has been formed, the reduction of the oil is brought about at a lower temperature. (See also Eng. Pats. 29,612 of 1910, 13,519 and 25,326 of 1911, 4702 of 1912, and 4144 of 1913; this J., 1912, 398, 650, 1190; 1913, 705.)—B. N.

Oil; Hydrogenated or hardened —— and process of making same. C. Ellis, Montclair, N.J. U.S. Pat. 1,097,308, May 19, 1914; date of appl., Nov. 22, 1912.

Edible products free from toxic metallic compounds, and of the consistence of butter or lard, are obtained by the catalytic hydrogenation of cottonseed oil or mixtures of edible oils.—C. A. M.

Fatty acids and their esters; Process for reduction [hydrogenation] of unsaturated ——. C. H. Maryott, Dallas, Tex. U.S. Pat. 1,097,456, May 19, 1914; date of appl., Nov. 30, 1912.

A solution of the fatty acid or oil in ether or other suitable solvent is treated with hydrogen in the presence of a catalytic metal of the palladium group, and in the absence of any material quantity of water or other liquid in which fats are insoluble.—C. A. M.

Fish oil; Process for the preparation of clear and odourless oils from ——. F. Bergius, Hanover, Germany. Eng. Pat. 18,925, Aug. 20, 1913. Under Int. Conv., Aug. 20, 1912.

Fish oil is deodorised by a single heating for several hours at a temperature between 250° and 300° C., without preliminary treatment with steam, etc. After deodorisation, purification of the oil may be completed by washing or steaming. (See also Eng. Pats. 15,491 of 1887, 7901 of 1906, and 15,012 of 1912; this J., 1888, 756; 1907, 420; 1913, 34, 436).—C. A. M.

Hydraulic presses for seeds and the like. Harburger Eisen- und Bronzewerke Aktienges., and G. Koeber, Harburg, Germany. Eng. Pat. 28,262, Dec. 8, 1913.

A constant quantity of material is supplied to the press, the piston of which is made to descend automatically in regulated stages by discharging definite amounts of the pressure-medium, *e.g.*, water, through a measuring device, the discharge being controlled by the movements of the hopper into which the material is fed.—C. A. M.

Press-filters for seeds containing oil. Harburger Eisen- und Bronzewerke Aktienges., Harburg, Germany. Eng. Pat. 29,913, Dec. 29, 1913.

The lateral inner walls of the filter-chamber are pierced with numerous small holes which open radially into larger holes at an angle to the axis of the latter, thus increasing the outlets for the oil without notably weakening the walls.—C. A. M.

Process for obtaining a substitute for boiled linseed oil Ger. Pat. 273,347. *See* XIII.

XIII.—PAINTS; PIGMENTS; VARNISHES RESINS.

White lead; Experiments on ——. R. S. Owens. J Phys. Chem., 1914, **18**, 461—473.

By precipitating lead hydroxide and carbonate, separatel or together, from solutions of lead acetate, crystals of th former were obtained varying in size according to th concentration and temperature employed. Lead carbo ate was not obtained in definite crystalline form, bu between narrow limits, the particles varied in size accordi to the conditions of precipitation. By keeping a mixtu of lead carbonate and hydroxide (separately precipitate under a solution of sodium acetate, white lead was obtain in particles of one size irrespective of the dimensions of t reacting particles. White lead obtained by co-precipitati of the carbonate and hydroxide was composed of rounde translucent, non-crystalline particles which were larg or smaller according as the precipitation was slow or rapi The commercial white leads examined, and those produc in the laboratory by the Wolterecl and Luckow electr lytic processes, were found to consist of particles cor sponding in size to those of white lead obtained by sl precipitation. When composed of the smaller partic precipitated white lead absorbed less oil and produc a better paint than when composed of larger partic uniformity in size of particles is, however, not necessar an advantage in a paint.—W. E. F. P.

Red lead ; Physico-chemical and technical studies on ——. Preparation of pure lead orthoplumbate. J. Milbauer. Chem.-Zeit., 1914, **38**, 477—479, 559—560, 566—567, 587—588.

The author critically reviews published methods for the preparation of pure red lead, and gives two new methods. *Dry method.*—Fifty grms. of potassium nitrate are slowly heated to 339° C., and a tube containing recrystallised lead chloride (m.pt. 484° C.) is immersed in the melt. Lead peroxide is gradually added with constant stirring, and the heating continued until oxygen ceases to be evolved, and the lead chloride in the tube has melted. The mass is then extracted with hot water, washed until free from nitrate, and dried at 110° C. Products thus obtained invariably contained 100% Pb_3O_4, were of a bright red colour, and had sp. gr. 8·7 at 17° C. *Wet method.*—A mixture of lead oxide and lead peroxide ($3PbO : 2PbO_2$) is gradually added to a concentrated solution of potassium hydroxide (150 to 200 grms. per 100 c.c.), and the liquid heated for 5 mins. A deposit of red lead is formed, with layers of other oxides above it, and the former, when washed with water, yields 100% Pb_3O_4. With other proportions of the lead oxides preparations ranging from green to brown or purplish-red in colour were obtained.

By extracting commercial red lead (58% Pb_3O_4) with boiling potassium hydroxide solution (100 grms. in 100 c.c.), there was obtained after 25 minutes a residue containing 92 to 96% Pb_3O_4, whilst a second extraction of 5 minutes yielded 99·7% Pb_3O_4. This method is not universally applicable, since it does not remove impurities such as calcium carbonate. (See also this J., 1913, 97, 151.)
—C. A. M.

Thitsi [Burmese lacquer]. L. Rosenthal. Farbenzeit., 1914, **19**, 1573—1574. Chem. Zentr., 1914, **1**, 1979.

"Thitsi" is obtained from the stems of the *Melanorrhoea usitata* as a grey, very viscous liquid of sp. gr. 1·0016 at 20° C., which on exposure to air becomes first brown and then, very rapidly, deep black. The drying of the lacquer is not accelerated by siccatives and is retarded by dry heat, the presence of moisture being essential. The constituent of the lacquer soluble in alcohol is identical with the urushinic acid, $C_{14}H_{18}O_2$, of Japan lac. The ether extract consists of a gummy substance soluble in water and a nitrogenous, coagulable substance, similar to a protein, which is insoluble in water ; this latter substance acts as an oxygen carrier in the drying of the lacquer, but loses its activity when heated above 60° C. The composition of two samples of the lacquer was : urushinic acid, 86·24, 83·24 ; gum, 3·08, 3·52 ; oil, 0, 0·53 ; residue insoluble in ether, 1·71, 2·14 ; moisture and volatile matter, 8·97, 10·57%.—A. S.

Patents.

Linseed oil ; Process for obtaining a substitute for boiled ——. E. F. Waentig. Ger. Pat. 273,347, Feb. 28, 1913. Addition to Ger. Pat. 272,465.

The oils are heated with water under pressure before being treated with superheated steam as described in the chief patent (this J., 1914, 604).—A. S.

Sealing and bottle wax ; Manufacture of a —— insoluble or sparingly soluble in alcohol. J. von Jasinski. Ger. Pat. 273,346, Aug. 17, 1913.

The resins obtained by extracting raw rubber or gutta-percha with solvents in which caoutchouc is insoluble, are used, together with the usual colouring and filling materials, in the preparation of the wax.—A. S.

XIV.—INDIA-RUBBER ; GUTTA-PERCHA.

Rubber ; Combustion method for the direct determination of ——. L. G. Wesson. J. Ind. Eng. Chem., 1914, **6**, 459—462.

A detailed description of the method for the determination of caoutchouc by converting it into the nitrosite and determining the carbon content of the latter by combustion (see this J., 1913, 614). Contrary to the statement of Alexander (see this J., 1907, 422, 538 ; 1911, 560) it was found that no appreciable quantity of carbon dioxide is formed during the conversion of caoutchouc into the nitrosite.—A. S.

Patents.

Rubber ; Method of vulcanising —— and means therefor. F. E. Blaisdell, London. Eng. Pat. 11,257, May 14, 1913.

The vulcaniser consists of a steam-jacketed vessel with means for admitting both steam and compressed air into the inner vessel. The rubber articles are placed in the inner vessel into which steam is then admitted, and in which the pressure is afterwards raised by the admission of compressed air. Steam is at the same time led into the outer jacket in order to raise the temperature to that necessary for vulcanisation. The temperature and pressure at which the goods are vulcanised can thus be regulated independently.—E. W. L.

Rubber, caoutchouc and the like ; Recovery of the solvent from ——. A. Boecler, Hamburg, Germany. Eng. Pat. 22,638, Oct. 7, 1913.

The work tables or rollers over which the materials used in the production of rubber textures, such as rubber-asbestos sheets, are passed while the solvent is evaporating, are completely enclosed in a casing, which is divided by the table or rollers into an upper and a lower compartment. The two compartments are connected by relatively small passage-ways at the sides, the bottom or sides of the lower compartment being inclined, and the walls of this compartment being provided with a cooling device for the purpose of collecting and assisting in the downflow of the condensed solvent, which is run off from an outlet at the bottom.—E. W. L.

Rubber ; Treatment [coagulation] of —— [by means of smoke]. F. Ripeau, Paris. Eng. Pat. 2281, Jan. 28, 1914.

The latex is poured into shallow pans which are then placed on a supporting stand in a smoke chamber. When the latex is coagulated sufficiently to enable the whole of it to be removed as a sheet, it is taken out, and may then be placed flat in a mould of such a size as to prevent lateral extension, and there subjected to gentle pressure in order to remove excess of water. The coagulated sheet may be turned and subjected to further smoking, and a further quantity of latex may then be coagulated upon it. The sheets are finally placed upon drying racks and kept in a drying shed until their surfaces are smooth and silky to the touch without being sticky or tacky.—E. W. L.

Manufacture of a sealing and bottle wax insoluble or sparingly soluble in alcohol. Ger. Pat. 273,346. *See* XIII.

XV.—LEATHER ; BONE ; HORN ; GLUE.

Colloidal tannins. M. C. Lamb. Leather Trades Year Book, 1914, 127—130.

Quebracho, containing 7 parts of tannin to 1 part of non-tannin, penetrates hide much more rapidly, especially in dilute solutions, than oak bark, which contains 7 parts of tannin to 4 parts of non-tannin Diffusion is slower with oak bark on account of its more colloidal character due to the relatively greater amount of non-tannins which it contains. Green pelt is first placed in liquors which have become mellowed by the accumulation of dissolved hide-substance and calcium salts and from which most of the astringent tannins have been removed by earlier packs of goods, or drawn grain and case-hardening is the result. The colloidal character of the tannin matter has an important bearing on the subsequent behaviour of the solution. C. F. Cross has found that the colloidal substance "tragasol" extracted from seeds, when mixed with tannin, produces a curdy precipitate in which the two substances are combined approximately in the ratio of their formula weights. The precipitate is insoluble in water but readily mixes with it; on heating a transparent and continuous solution is formed with a great increase of viscosity. The substance is suitable for tanning as the transition to the insoluble condition by combination with pelt is comparatively slow. Goods may be placed, after deliming, direct into a concentrated solution of the tragasol-tannin precipitate, with no water added except that held by the pelt, and there is no liability of causing drawn or case-hardened grain. Such strengths can be used as to tan sole-butts completely in 30 hours. The mixture is best applied in the drum and the leather produced is water-resistant and of good colour as there is little oxidation and the tragasol-tannin complex parts with water very slowly. Tannage may also be carried out first with the colloidal material followed by the use of liquid extract in undiluted form.—D. J. L.

Tan; Power from spent ——. C. E. Parker. Leather Trades Year Book, 1914, 201—202.

The combustion furnace (producer) for converting tan into power gas is necessarily larger than that for a similar plant using coke or anthracite. Before feeding into the producer, the tan is put through a tan-press to remove excess of moisture. Special features in the scrubbers for cleaning the gas are necessary as trouble may arise from clogging of valves or piston if tar is carried forward with the gas. A very efficient gas is produced from spent tan, some materials being better than others in this respect. Myrobalans, on account of their oily nature, give a good gas of high calorific value. Crude tar is deposited in the washer, but the quantity of saleable by-products (oils) obtainable therefrom has, so far, not been found to render recovery profitable.—D. J. L.

Leather finishing: The uses of collodion in ——. C. A. Higgins. Leather Trades Year Book, 1914, 148—151.

Solutions of collodion cotton or nitrocellulose (celluloid solution, soluble cotton mixture, pyroxylin, nitro-cotton solution and zapon) are finding application as a varnish or a vehicle for the application of pigments and decorative materials on account of the ease of application and the strength and insoluble nature of the film produced. Careful selection of solvents and efficient airing of leather after coating should leave no cause of complaint of residual odour. The advantages of the process over the old method of japanning with linseed oil are that no ovens are required, sunning is unnecessary, and the leather retains its natural grain surface owing to a thinner coating being used in the collodion process. The enamel is stronger and has not the brittleness or liability to crack of oil-enamelled leather. —D. J. L.

XVI.—SOILS; FERTILISERS.

Phosphate rock; Reserve supply of —— in the United States. W. H. Waggaman. J. Ind. Eng. Chem., 1914, **6**, 464—465.

The estimated supplies of rock grading from 58 to 70% "bone phosphate of lime" are as follows. In the case of low-grade phosphate and wash-heaps, the equivalent of high-grade phosphate has been calculated. The estimates for Kentucky and Arkansas, where little development work has been done, are probably not close to the truth, but are regarded as ultra-conservative. High-grade rock: Utah, Idaho, Wyoming, and Montana, 2,500,000,000 tons; high-grade equivalent of all grades: Utah, Idaho, Wyoming and Montana, 7,500,000,000; Florida, 354,300,000; Tennessee, 115,075,000; S. Carolina, 10,000,000; Arkansas, 20,000,000; Kentucky, 500,000; high-grade equivalent of wash-heaps: Florida, 20,000,000; total 10,519,875,000 tons. Taking the average output during the life of the deposits as three times the present output (nearly 3 million tons in 1912), the available supplies will last for over 1100 years provided proper mining methods are employed and means devised for utilising the lower-grade material. Attention is drawn to the increasing use of raw ground phosphate rock as a fertiliser.—A. S.

Basic slag; Sources of error in the analysis of ——. M. Popp. Chem.-Zeit., 1914, **38**, 741—742.

The sample should be well mixed after it has been passed through the usual sieve, since the sifting operation tends to yield layers of material of unequal composition. The time of contact of the sample with 2% citric acid solution should be exactly 30 mins. at 17·5° C., with continual shaking, and the solution should then be poured on a large filter; further quantities of the solution must not be poured on to the filter as the latter empties. Fifty c.c. of the filtrate are treated with 25 c.c. of iron citrate solution (see this J., 1913, 953), 1 c.c. of 3% hydrogen peroxide, and 25 c.c. of magnesia mixture.—W. P. S.

Ammonium citrate; A comparison of neutral —— with sodium citrate and N/10 citric acid. P. Rudnick, W. B. Derby, and W. L. Latshaw. J. Ind. Eng. Chem., 1914, **6**, 486—487.

In the determination of insoluble phosphoric acid in phosphatic fertilisers, sodium citrate solution of sp. gr. from 1·043 to 1·231 gave results considerably higher than those obtained with neutral ammonium citrate solution of sp. gr. 1·09. N/10 citric acid gave results agreeing well with those furnished by ammonium citrate and has the advantages that it is more easily prepared and standardised than the latter, and allows of the extraction and filtration being performed more rapidly.—A. S.

Volumetric determination of cyanamide. Grube an Krüger. *See* VII.

Use of dicalcium phosphate ("phospho-gelose") an kieselguhr for clarifying cane juice in Brazil. Pelle *See* XVII.

Patent.

Phosphate slag for agricultural purposes; Treatment of — H. Küppers and Act.-Ges. Peiner Walzwerk, Peir Germany. Eng. Pat. 922, Jan. 13, 1914.

Silicious material, *e.g.*, sand, is added to the molten sl as it leaves the converter and is intimately incorporat by a rotary stirrer which is plunged beneath the surfa of the mixture after a crust has been allowed to form. T phosphoric acid of the slag may be rendered almost co pletely soluble in citric acid by the process.—F. Sodn.

XVII.—SUGARS; STARCHES; GUMS.

Sugar; Evolution of —— in the beetroot during its sec period of vegetation. M. Levallois. Bull. Assoc. Ch Sucr., 1914, **31**, 903—909.

During the period of flowering of the sugar beet the wei t of the root gradually increases, decreasing again slowly a r the appearance of the seed. On the contrary, the suc e content rapidly falls, the decrease observed in e experiments of the author being from 18—21% in A il to 8% at the moment of flowering in August and to o on the formation of the seed in September and Octo r. —J. P.

Maize; Manufacture of sucrose from ——. J. B e Dent. Zuckerind., 1914, **39**, 538—540.

In a large scale experiment, maize grown in Tucu n, Argentina, was crushed in a double 3-roller mill. n extraction of 55% by weight was obtained and the had the composition: Brix reading, 15·9; sucrose, 8·75; and purity, 55·0%. After clarifying by the addition of lime and soda, allowing to settle, sulphiting to a slightly acid reaction, and boiling, the composition was: Brix reading, 14·7; sucrose, 8·69; and purity, 59·1%. The concentrated syrup did not crystallise readily in the pan, but after breaking the vacuum, and allowing the strike to stand for 10 mins., a fine grain separated, which on subsequently centrifuging and "covering" with steam gave a sugar of the composition: water, 1·15; sucrose, 97·6; ash, 0·34; and reducing sugars, 0·31%. In a laboratory experiment with an extraction of 64·5% by weight, and a sucrose content in the juice of 12·27, the yield of first and second sugars, calculated to 100° polarisation, was 5·35 and 1·25% respectively. It is concluded that the working-up of naize juice in the factory presents no inconvenience; ut that on the agricultural side there are considerable difficulties, namely, the necessity of harvesting within 8—21 days to avoid a great loss of sucrose by inversion; he brief duration of the point at which the maximum of ucrose is reached; and the sensitiveness of the plant to iseases and pests, especially in its early period of growth. —J. P. O.

agasse; Weight of —— in [sugar] factory control. G. L. Spencer. Intern. Sugar J., 1914, **16**, 254.

s the author's method of determining the weight of agasse, the weight of the mixed juice is deducted from at of the cane and saturation water. This procedure is aimed to be much more reliable than that in which the tio of the percentage of fibre in the bagasse and in the ne is determined, though it is subject to certain errors, ., the partial drying of the bagasse in passing through e mills, and the possibility of water entering the juice ns from the mill journals. Error in other directions is minated as far as possible by the use of automatic mpling devices, by taking the actual weights of cane d juice, and by the measurement of the water.—J. P. O.

calcium phosphate ("phospho-gelose") and kieselguhr; Use of —— for clarifying cane juice in Brazil. L. Pellet. Bull. Assoc. Chim. Sucr., 1914, **31**, 849—858.

E raw sulphited juice is treated in mixing tanks with ie and a mixture of dicalcium phosphate and kieselguhr, ssed through heaters, which raise it to 95°—100° C., d sent to the decantation tanks. After settling, clear and brilliant juice is obtained, whilst the ms are filtered, washed, and dried, to be subsequently ployed as a fertiliser, their composition being: organic tter, 64·25; organic nitrogen, 1·47; total phosphoric d, 11·16; total lime, 12·87%. Depending upon the ity of the juice, the amount of the dicalcium phosphate kieselguhr used may vary from 0·8—2·8 kilo. and 0·3— kilo. respectively per ton of cane ground.—J. P. O.

rose; Modification of the double polarisation (Clerget-lerzfeld) method of determining the —— in (beet) molasses. . Stanek. Z. Zuckerind. Böhm., 1914, **38**, 429—440. See also this J., 1914, 96 and 433.)

obviate the influence of salts and optically-active ogenous substances in the double polarisation method n applied to beet molasses, the author proposes to e the direct reading in the presence of exactly the same unt of potassium chloride and citric acid as the inver- reading, clarification being effected with bromine er in place of lead acetate. *Preparation of the citric solution.*—380 grms. of pure potassium hydroxide are ted with about 250 c.c. of water, and when about e-quarters have dissolved, the liquid (solution 1) is red off, the remaining hydroxide being dissolved in t 250 c.c. of water (solution 2). 400 grms. of pure c acid are mixed with 100—200 c.c. of water, and tion 1 gradually added while stirring. After cooling, liquid is diluted to about 750 c.c., neutralised with tion 2, phenolphthalein being used as indicator, and finally after again cooling made up to 1000 c.c. This constitutes the neutral potassium citrate solution, 10 c.c. of which will combine with the 5 c.c. of hydrochloric acid (sp. gr. 1·188) used for inversion, forming potassium chloride and free citric acid. 500 c.c. are treated with 250 c.c. of hydrochloric acid (sp. gr. 1·188), cooled, and made up to 1000 c.c. This is the potassium chloride and citric acid solution, 20 c.c. of which contain the equivalent of 5 c.c. of hydrochloric acid (sp. gr. 1·188) used for inversion, combined as potassium chloride. *Procedure for beet molasses.*—Twice the normal sugar weight of the sample is dissolved in 200 c.c. of water without the addition of any clarifying agent. For the direct reading, 50 c.c. are placed in a 100 c.c. flask with 20 c.c. of the potassium chloride and citric acid solution, and the liquid made up to the mark with saturated bromine water, being polarised in the 200 mm. glass tube. For the inversion reading, 50 c.c. of the normal molasses solution are hydrolysed with 10 c.c. of hydrochloric acid (1 part of acid of sp. gr. 1·188 to 1 of water) in the usual manner, cooled, and 10 c.c. of the neutral potassium citrate solution and sufficient bromine water added to make up the volume to 100 c.c. After 20 minutes, the liquid is polarised in the 200 mm. water-jacketed tube, preferably at 20° C., and the content of sucrose calculated from the formula:

$$\frac{(D-I)\,100}{132 \cdot 6} \text{ for } 20^\circ \text{ C.; or } \frac{(D-I)\,100}{142 \cdot 6 - \frac{t}{2}} \text{ at any other}$$

temperature, t, D and I being the direct and inversion polarisations respectively. Under the conditions of working, bromine has no effect either on the sucrose or on the invert sugar. The coefficient of 132·6 was established with the new procedure in the presence of molasses salts and nitrogenous optically-active bodies for the concentration used. This modification gives results that agree well with the Andrlik-Stanek method (this J., 1911, 62), but are about 1% higher than those obtained by the ordinary procedure, which is known to be incorrect on account of the influence of optically-active amino-acids. —J. P. O.

Adsorption of dextrose. II. P. Rona and K. v. Tóth. Biochem. Zeits., 1914, **64**, 288—295. (See this J., 1909, 535.)

The inhibitive action of acetic acid on the adsorption of dextrose by charcoal (*loc. cit.*) must be due to the undissociated molecules of acid, for it is not affected by addition of sodium acetate or hydrochloric acid. The power of inhibition depends on the extent to which the inhibitive substance is itself adsorbed, and this again depends on the extent to which it lowers the surface tension of water; for example, the inhibitive action of propionic acid is greater than that of acetic acid, but less than that of butyric or isobutyric acid. The strong mineral acids, which are only weakly adsorbed, have very little influence on the adsorption of dextrose, whereas in the case of the urethanes (methyl, ethyl, propyl and butyl) adsorption by charcoal and inhibition of adsorption of dextrose are both strongly pronounced, and both increase with the molecular weight of the urethane. The distinction between "mechanical" adsorption by charcoal and "electrochemical" adsorption by kaolin and ferric hydroxide (*loc. cit.*) is well exhibited by the urethanes, which are strongly adsorbed by charcoal, but not at all by kaolin or ferric hydroxide.—J. H. L.

Laevulose; Action of ultraviolet rays on ——. Formation of formaldehyde and carbon monoxide. A. Ranc. Biochem. Zeits., 1914, **64**, 257—287.

Pure aqueous solutions of lævulose, exposed to the action of ultraviolet rays, undergo decomposition even at 20° C., with production of gas consisting of carbon monoxide together with small quantities of formaldehyde and carbon dioxide. The solutions afterwards contain aldehydic and acid substances. (See also Bierry, Henri and Ranc, this J., 1910, 1029; Berthelot and Gaudechon, this J., 1910, 1081).—J. H. L.

PATENTS.

Megass furnaces. The Stirling Boiler Company, Ltd., London. From E. C. Knight, Tucuman, Argentine. Eng. Pat. 12,141, May 24, 1913.

In furnaces in which the megass is passed through a retort on its way to the fire, a pipe containing a plunger communicates at one end with the retort, and near the other with a regulating shoot above it. The shoot has a flap arranged to open and drop a fresh charge of megass as the plunger is returning.—O. E. M.

Sugar juices; Apparatus for boiling —— by the steam from the juice, without addition of fresh steam. E. Portemont. Fr. Pat. 465,565, Dec. 1, 1913.

The heating apparatus contains two concentric tube systems, A and B. The system, A, which serves to heat the juice initially, is supplied through the pipe, 13, with steam say from the Pauly apparatus, and the system, B, through the pipe, 16, with steam from the juice, the steam in each case being utilised for two or more effects. Condensed water is discharged through the pipes, 14 and 17, and non-condensable gas through the pipes, 15 and 18.—L. E.

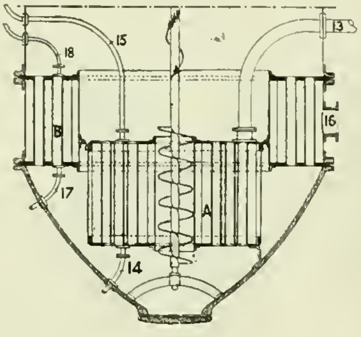

Fig. 1.

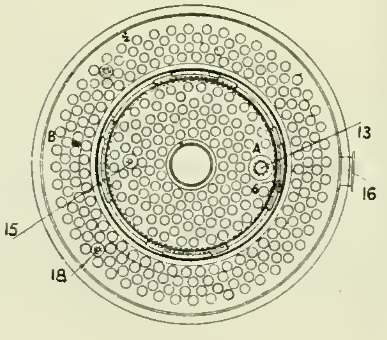

Fig. 2.

XVIII.—FERMENTATION INDUSTRIES.

Enzymes; Specific action of —— with regard to their synthetic properties. E. Bourquelot. J. Pharm. Chim., 1914, 9, 603—606.

When glucosidase-β is allowed to act upon an alcoholic solution of dextrose the β-alcoholglucoside is produced. At the same time the equilibrium between the α- and β-glucoses becomes disturbed, with the result that the whole of the dextrose becomes converted into the β-modification. On the other hand, treatment of a similar alcoholic solution of dextrose with glucosidase-α leads to the production of α-alcoholglucoside. Similar results can be obtained by treating a solution of galactose with galactosidase-α or -β. Methylgalactoside-β has $[\alpha]_D=$ —0·419°.—F. Shdn.

Benzoylcarbinol and other substances; Formation of —— from phenylglyoxal by the action of fermenting yeast. H. D. Dakin. J. Biol. Chem., 1914, 18, 91—93.

When phenylglyoxal is added to an actively fermentin mixture of dextrose solution and yeast, the main product of the action are benzoylcarbinol and *l*-mandelic acid small amounts of benzyl alcohol, benzaldehyde, an phenylpyruvic acid are also formed.—W. P. S.

Nitrogen; Question of the assimilation of elementary —— by yeasts and mould fungi. A. Kossowicz. Biochem Zeits., 1914, 64, 82—85.

No evidence for the assimilation of elementary nitroge was afforded by the author's experiments, in whic various organisms, including *Aspergillus niger, Penicilliu glaucum*, and some yeasts, were cultivated for three week in nitrogen-free nutrient liquids (cp. Lipman, this J., 191 1273).—J. H. L.

Yeast; Asymmetric and symmetric action of —— on racem combinations of naturally occurring amino-acids. Ehrlich. Biochem. Zeits., 1914, 63, 379—401. (S also this J., 1905, 683; 1907, 480; 1909, 848; 1910, 835 1911, 566.)

Fermenting yeast acts selectively on racemic compoun of alanine, valine, leucine, isoleucine, serine, glutam acid, phenylalanine, histidine and the dipeptide alan glycine, so that in some cases after the whole of t naturally occurring isomeride has been decomposed abo 60—70% of the other form can be recovered unchange There is no such selective action with aspartic ac proline and tyrosine, both forms of which are decompos at the same rate. In his experiments the author employ only one yeast, a top-fermentation race.—J. H. L.

Yeast autolysis; Synthetic processes of ——. N. Iwan Biochem. Zeits., 1914, 63, 359—368.

Suspensions of hefanol in water, autolysed until most the protein had been hydrolysed (*e.g.*, for 24 hours 53°—55° C.) and then rendered alkaline with dipotassi phosphate, recovered 4—9% of their original prote content within 24 hours, whilst at the same time content of proteolytic products precipitable by l acetate (peptic products) correspondingly decreased. is concluded that, provided proteolysis has advanced enough in the autolysis of yeast, it is possible to reve to some extent the hydrolytic action of the peptase pres by rendering the liquid alkaline with dipotassium p phate.—J. H. L.

Yeast juice; Synthesis of nitrogenous substances in mac tion ——. S. Kostytschew and W. Brilliant. physiol. Chem., 1914, 91, 372—391.

Lebedeff's maceration yeast juice (this J., 1911, contains endotryptase and a considerable quantity proteins. A large proportion of the proteins is hydrol on keeping the juice, slightly acidified with acetic at 34° C. for 2 days, though the remainder is not atta even in the course of 9 days. This hydrolysis is foll by synthesis on adding a considerable quantity of s to the juice (2—4 grms. of dextrose per 8 c.c.); synthesis only occurs, however, if hydrolysis has fairly considerable, a fact which appears to show the synthesis is aided by the proteolytic enzyme. result of synthesis, the amount of "protein nitro determined by Stutzer's method of precipitation copper hydroxide, may increase by as much as 16 that in the original juice; the increase appears to be less however, if the "protein nitrogen" is detern by precipitation with basic lead acetate, and it is cluded therefore that the synthetic products are identical with the true proteins of yeast juice.—L. E.

Enzymes ; Contribution to the chemistry of proteolytic ——. E. Herzfeld. Biochem. Zeits., 1914, **64**, 103—105.

It is suggested that the active constituents of pepsin and trypsin are respectively peptones and amino-acids, *i.e.*, compounds identical with or similar to the products of their activities. As regards their content of nitrogen, and of dialysable substances capable of reacting with triketohydrindene hydrate, there is a certain resemblance between pepsin and peptones and between trypsin and amino-acids or their derivatives. Moreover, peptones exert a proteolytic action comparable with that of pepsin, but only towards their parent proteins, *e.g.*, albumin is decomposed by peptone from albumin, but not by silk peptone. Similarly, amino-acids exhibit tryptic activity, which, however, does not appear to be specific like the peptic action of peptones.—J. H. L.

Yeast ; Relation of protein substances of —— *to sucrase.* P. Thomas. Comptes rend., 1914, **158**, 1597—1600. (See also this J., 1913, 762 and 803.)

Cerevisin proved capable of hydrolysing sucrose, and the action could be increased by finely powdering, warming to 52° C., or boiling for a short time with a weak solution of urea. The other protein isolated from yeast had no such action. Sucrase is considered to be derived from cerevisin.—F. Shdn.

Yeast ; New observations on the production of pyruvic acid by ——. A. Fernbach and M. Schoen. Comptes rend., 1914, **158**, 1719—1722. (See this J., 1914, 97.)

A solution of 1·8 kilos. of inverted sucrose in 24 litres of water containing mineral salts, was fermented by the myco-yeast of Duclaux in presence of chalk, and 279 grms. of calcium salts were obtained (cp. *loc. cit.*). The latter were acidified and extracted with ether, and the soluble acids distilled *in vacuo*. The quantity of pyruvic acid in the distillate corresponded to only 1·23% of the sugar fermented, but the residue from the distillation contained much larger quantities of a condensation product of pyruvic acid. From the quantity of acetic acid produced by oxidation of the calcium salts (see above) with chromic acid, the authors conclude that the amount of pyruvic acid present was 8% of the sugar originally fermented. Experiments with other yeasts gave similar but not quantitatively identical results. In the course of fermentation the amount of pyruvic acid appears to increase in proportion to the sugar consumed, until fermentation is complete, after which it diminishes.—J. H. L.

Hops ; Aroma of ——. *The volatile oil in relation to the geographical sources of the hops.* F. Rabak. J. Agric. Research. 1914, **2**, 115—157.

The essential oil was extracted from hops grown in various places during several seasons. The physical properties and results of fractional distillation showed strong similarities amongst related oils and dissimilarities amongst unrelated oils. The following figures give the average ester numbers of the respective oils: Bohemia 3·5 ; Washington 52·8 ; New York 50·9 ; Oregon 58·8 ; alifornia (five districts) 41·0—51·0. The ester numbers f the oils from hops of any particular season or locality ere found to be very similar.—F. Shdn.

ines ; Solubility of bitartrate in —— *: an indication of dilution.* L. Tissier and H. François. Ann. Falsif., 1914, **7**, 251—254.

nce wines in their original condition are saturated ith potassium bitartrate, a determination of the amount the salt that can be dissolved by a sample of wine fords an indication as to whether and to what extent the ine has been diluted. Thus, of 14 samples of undiluted d wine, only one dissolved as much as 9 mgrms. of bitarate per 100 c.c. at 25° C., whilst most of the others ssolved none or even lost a few mgrms. (*i.e.*, were ghtly supersaturated). Three of the samples also, ere cooled to 2° C. for 10 days prior to the determination, it only one was affected thereby, the amount of bitartrate ssolved increasing from 9 to 19 mgrms. On diluting the wines to 10%, the amounts of bitartrate dissolved per 100 c.c. at 25° C., ranged from 23 to 63 mgrms. In the case of undiluted white wines, the solubility of bitartrate ranged from 48 to 63 mgrms. per 100 c.c. at 25° C. ; cooling the wine to 2° C. for 10 days prior to the determination, increased this solubility by 8—19 mgrms., whilst dilution of the wine to 10% increased the solubility by 44—51 mgrms.—L. E.

Grain ; Treatment of —— *[in the distillery] for the recovery of oil, by the aid of enzymes.* A. Vasseux. Bull. Assoc. Chim. Sucr., 1914, **31**, 882—886.

The germ of the grain (maize), and amounting to 20%, and which contains almost all the oil, is separated, and saccharified at 72°—75° C. with the addition of 2—3% of malt, the remaining 80% of the grain being treated in the usual manner. It is claimed that in this way the recovery of oil is greater, and the flavour of the finished spirit is better, than by following the usual procedure.—J. P. O.

Cognac ; Maturation of ——. E. P. Häussler. Z. öffentl. Chem., 1914, **20**, 184—197.

Distillates from wine were stored for 9—15 months in contact with oak chips (*e.g.*, 400 grms. in 3600 c.c.) and analysed from time to time. The gravity of the liquids increased slightly and in most cases the alcohol-content decreased by 1—2 %, but fluctuated considerably ; alcohol was probably absorbed by the wood in amounts depending on the temperature. The content of extract increased, *e.g.*, from 0·1 to 2·9 grm. per litre in 2 months and to 7·3 grms. in 15 months. The reducing substances, calculated as dextrose, constituted 4—8% of the total extract before and 8—14% after hydrolysis with acid. The volatile and total acidities increased uniformly with the time, and the ash increased slightly. The content of higher alcohols fluctuated without any general rise or fall, and the content of esters (determined in the steam distillate) showed no considerable change. A pure aqueous solution of alcohol, treated similarly to the wine-distillates, underwent similar changes of composition, and afterwards responded positively to some of the usual reagents for vanillin. Wine distillates stored for 12 months in glass vessels underwent no considerable change in composition. The author considers that evidence as to sophistication of brandy may be obtained from the ash-content which should not greatly exceed 0·3 grm. per litre, and from the contents of extract and reducing substances (see above).—J. H. L.

Alcohols ; Action of formaldehyde on —— *in presence of sulphuric acid.* J. Buraczewski and W. Matejko. Oesterr. Chem.-Zeit., 1914, **17**, 130—131.

A reddish-brown coloration was produced when alcohol was mixed with an equal volume of concentrated sulphuric acid in presence of a small quantity of formaldehyde. By boiling the mixture and then diluting with water, a solid product of indeterminate composition was obtained. Since the higher alcohols, fusel oil, etc., gave the coloration more readily, and with diluted acid, the reaction was made the basis of a colorimetric determination of fusel oil in raw spirit. Sulphuric acid diluted with half its volume of water, and an equal volume of 40% formaldehyde solution were the reagents employed.—G. F. M.

Patents.

Beer or other liquids ; Method of clearing ——, *and apparatus therefor.* E. R. Curtis, Brighton, and J. W. Huxley, Guildford. Eng. Pat. 13,619, June 12, 1913.

The beer is passed, under high pressure, through a vessel mounted axially on a revolving shaft, the inlet and outlet for the beer being situated at or near the axis. The revolving vessel, which may be contained in an outer, stationary one, is fitted with vanes so that the liquid is caused to rotate with the vessel ; the solid particles thus move towards the periphery and clarified liquid is discharged through the outlet. The revolving vessel may be fitted with a disc so placed that the beer circulates round it in passing through the vessel. In another form of apparatus, the beer is introduced through tubular arms mounted radially on the revolving shaft.—L. E.

Wort ; Apparatus for extracting ——. W. T. Ramsden. London. Eng. Pat. 19,745, Sept. 1, 1913.

A cylindrical basket, mounted horizontally on a rotatable shaft and closed at one end, is fitted at the other, open end with an inturned flange. The mash is fed into the basket at the closed end, and the wort passes by centrifugal action through the wall of the basket to an outer casing fitted with an outlet. A screw conveyor, mounted on a shaft passing axially through the shaft which carries the basket, causes the mash from which the wort has been extracted to flow over the inturned flange. Sparging water is introduced through a perforated pipe extending within the basket.—L. E.

XIXa.—FOODS.

Bacteria in milk ; A comparison of the microscopical method and the plate method of counting ——. J. D. Brew. New York Exper. Stat., Bull. No. 373, Feb., 1914, pp. 1—38.

Although there is little relationship between the results obtained by the plate method and the direct microscopic method when used for counting the number of bacteria in single samples of fresh milk, there is a certain relationship when a series of samples is examined ; the microscopic method yields higher and probably more accurate figures. In the case of milk showing plate counts of less than 10,000 bacteria per c.c., the count by the microscope shows about 44 times as many individual bacteria, or 17 times as many when the clumps and isolated bacteria are counted as units. With more than one million bacteria per c.c., the microscope count shows about 5 times as many as the plate count, or even less than the latter count when the clumps are taken as units. The difference is due to the fact that a colony on an agar plate develops either from a clump of bacteria or from a single individual. Since the two counts are practically the same when the plate count is approximately one million per c.c., it appears that nearly all the bacteria in market milk grow on nutrient agar media when incubated at ordinary temperatures. The microscope count, in spite of its limitations, possesses the advantage that in some cases it shows the presence of bacteria not adapted to grow on gelatin or agar ; further, the results may be obtained within a few minutes of taking the sample. At the same time, the adoption of the microscopical method of counting bacteria in milk would involve a complete readjustment of bacteriological standards, and more data should be obtained before any such change is made.

The microscopical method employed by the author consisted in placing 0·01 c.c. of the milk (by means of a capillary pipette) on a glass slide and spreading the drop over a surface of 1 sq. cm. ; the milk was then dried, treated with xylene to remove fat, fixed with 95% alcohol, and stained with methylene blue. The counting was done under an oil-immersion lens of 1·9 mm. focus. The medium employed in the plate method consisted of Liebig's meat extract, 5, Witte's peptone, 10, agar, 15, lactose, 10 grms., and water, 1 litre ; the plates were incubated for 5 days at 21° C.—W. P. S.

Milk ; Composition of ——. H. D. Richmond. Analyst, 1914, **39**, 243—248.

The average composition of 19,807 samples of milk received from the farms during 1913, was as follows :—

	Morning's milk.	Evening's milk.	Average.
Specific gravity	1·0319	1·0315	1·0317
Fat, %	3·52	3·83	3·67
Solids not fat, %	8·82	8·79	8·81

During the months of May, June and July, a small percentage of the morning milks yielded less than 3% of fat. The percentages of fat and the aldehyde figure (see this J., 1911, 148) were determined in a number of samples of cream ; the average aldehyde figure, calculated on the cream devoid of fat, was 20·8, practically the same figure as is found in the case of milk devoid of fat. The aldehyde figure is of use for detecting whether a cream has been watered or not, for should a cream be low in fat due to the addition of milk, no alteration of the figure would take place, whilst added water would lower it.—W. P. S.

Milk ; Determination of the viscosity of —— *as a means of detecting addition of water.* W. D. Kooper. Milchwirtsch. Zentr., 1914, **43**, 169—179, 201—208. Chem. Zentr., 1914, **1**, 1975—1976.

No definite relation was observed between the viscosity of milk and its fat content or specific gravity, although in general a high fat content corresponded with high viscosity. In 50 samples of mixed milk the relation between the total solids, T, and the viscosity constant, V (ratio of the times of efflux of the same volume of milk and of water from the viscosimeter at 15° C.) was, on the average, $T=\frac{V}{0{\cdot}1384}$. In the case of milk from which a portion of the fat has been removed, or to which water or skimmed mil has been added, the ratio $\frac{V}{0{\cdot}1384}$ gives a higher value tha corresponds with actual percentage of total solids.—A. S

Proteins of the maize kernel ; Nutritive properties of the —— T. B. Osborne and L. B. Mendel. J. Biol. Chem., 1914 **18**, 1—16.

Experience in the use of maize as a food has led to th belief that, compared with other foodstuffs, it is in som respects inadequate. This deficiency appears to be du to the fact that zein, the chief protein of maize, does n yield amino-acids which are necessary for nutritio For instance, glycocoll, lysine, and tryptophane a entirely absent from the products of hydrolysis of zei whilst arginine and histidine are present in only sma amounts. The addition of amino-acids considerab increases the food value of zein, and, although this brought about to some extent by the other proteins maize when the latter is used as a whole, a very sma addition of a substance such as lactalbumin to maize foo would probably be of great advantage.—W. P. S.

Crude fibre [in grain, bran, etc.] ; New method for t determination of ——. H. Stiegler. J. f. Landw., 191 **61**, 399—426. Chem. Zentr., 1914, **1**, 2016—2017.

Three grms. of the sample (less if it contain a hi proportion of crude fibre), in the form of an impalpa powder, are mixed with 20 c.c. of water in a 300 c Soxhlet flask such as is used for sterilising milk, 60 c of hydrochloric acid of sp. gr. 1·19 are added and w mixed, and after 10 mins. the mixture is diluted to 200 c with boiling water and heated for 1 hour on the wat bath whilst a slow current of air is drawn through. Af allowing to settle, the clear liquid is drawn off throug tube of 7 mm. diam., with a contracted portion ab 2 cm. from one end and having therein a roll of gl wool which projects about 1 cm. from the end of the tu whilst drawing off the liquid the end of the roll of gl wool is kept quite close to the residue at the bottom of flask ; the glass wool is subsequently knocked out of tube into the flask and the tube rinsed. The conte of the flask are neutralised and an excess of 50 c.c. of potassium hydroxide solution added, the mixture diluted 200 c.c. with boiling water, and heated for ½ hour on water-bath whilst a current of air is drawn throu The insoluble residue is collected on asbestos in a Go crucible, washed with 500 c.c. of hot water, and w alcohol, left in contact with ether for ½ hour, then dried 2 hours at 100°—105° C., weighed, the residue incinerat and again weighed. The results agree well with corrected values for crude fibre obtained by Weene method and with the cellulose values obtained by Toll method.—A. S.

Sugars in gingerbread and similar products; Separation and determination of ——. J. König and W. Burberg. Z. Unters. Nahr. Genussm., 1914, 27, 761—774.

A quantity of 6·25 grms. of the powdered sample is mixed in a 250 c.c. flask with 25 c.c. of water, and, during a period of 2 hours, quantities of 50 c.c. of 96% alcohol are added until the flask is filled to the mark. The alcoholic solution is then filtered, evaporated to small volume, and diluted to 250 c.c. with water. Portions of this solution are used for the determination of the polarisation before and after inversion, total sugars (total solids by evaporation), dextrose and invert sugar (by Soxhlet's method), and sucrose. Starch and dextrins are determined in the portion insoluble in alcohol.—W. P. S.

Patents.

Flour or like material; Treatment of —— [*with liquids*]. E. Samuelson, Banbury, Oxon., and J. Backhouse, Bootle, Lancs. Eng. Pat. 12,299, May 27, 1913.

Flour is introduced into the bottom of a chamber, preferably wider at the top than at the bottom, by means of a screw conveyor, or through a hollow vertical shaft, leading to a spreader, and is carried upwards by means of revolving lifters, beaters or brushes and fan blades arranged on the vertical shaft. Liquid is atomised in a separate chamber below the flour chamber, and passes upward into the latter, where it comes into intimate contact with the flour. The atomisers are arranged tangentially and the supply of atomised liquid may be regulated automatically by means of a valve actuated from the flour-supply valve.—E. W. L.

Grain cleaning appliances; Treatment of residue from ——. T. Robinson & Son, Ltd., C. J. Robinson, and T. J. Stevenson, Rochdale, Lancs. Eng. Pat. 13,037, June 5, 1913.

Residues from grain cleaning appliances are freed from dust and then passed through closed, air-circuit aspirators, whereby the small seeds and impurities are separated and collected in different compartments.—W. P. S.

Cream, milk, and the like: Apparatus for use in pasteurising ——. H. Tödt, Lensahn, Germany. Eng. Pat. 27,208, Nov. 26, 1913.

A vertical rotating drum is mounted in a vessel contained in a casing. The liquid to be pasteurised is passed upwards through the space between the drum and the vessel, and the inner wall of the drum and the outside of the vessel are heated by jets of steam. The heated liquid leaving the top of the apparatus is conducted to a spraying chamber and thence to a cooling apparatus. The drum and the vessel may be slightly conical so that the width of the space between them can be adjusted by raising or lowering the drum. Means are provided for removing condensed water from the apparatus.—W. P. S.

XIXb.—WATER PURIFICATION; SANITATION.

Hardness of water; Determination of ——. L. W. Winkler. Z. anal. Chem., 1914, 53, 409—415.

The total alkalinity is found by Lunge's method; carbon dioxide is then reduced to about 1 c.c. per 100 c.c. of the water by means of a current of air, and the total permanent hardness found by Blacher's method (this J., 1913, 158). The hardness due to lime is found by running a standard solution of pure sodium oleate into a measured quantity of the water containing alkaline Rochelle salt solution, until a permanent lather is produced. The magnesia, which is not precipitated, is found by difference.—O. E. M.

Manganese in water, its detection and determination. J. Tillmans and H. Mildner. J. Gasbeleucht., 1914, 57, 496—501, 523—526, 544—547.

Manganese in water, in the absence of iron salts and other oxidising compounds, may be detected by rendering the water alkaline, shaking it in a vessel containing air, acidifying with sulphuric acid and adding potassium iodide and starch, when a blue coloration develops. Iron salts may be removed previously by means of zinc oxide, or sodium phosphate may be added to prevent their action on the potassium iodide. Very small quantities of manganese (down to 0·05 mgrm. per litre) may be detected by shaking the water with potassium periodate, acidifying with glacial acetic acid and adding a solution of tetramethyldiaminodiphenylmethane; a blue coloration is obtained when manganese is present. Excess of periodate does not interfere with the reaction, but iron salts, when present in large quantity, should be removed. To determine manganese the authors recommend a modification of Marshall's process. Ten c.c. of the water are treated with 0·5 c.c. of dilute sulphuric acid (1 : 3), from 3 to 10 drops of 5% silver nitrate solution and 0·5 grm. of potassium persulphate, and heated for 20 mins. in a boiling water-bath. After cooling, the permanganate coloration obtained is compared with that exhibited by an alkaline standard phenolphthalein solution, prepared by dissolving 50 mgrms. of pure phenolphthalein in 100 c.c. of absolute alcohol and diluting to 100 times its volume with 50% alcohol; 1 c.c. of this solution, when diluted with 10 c.c. of water and treated with 4 drops of $N/1$ sodium hydroxide solution, gives a coloration equivalent to the permanganate coloration shown by 1 mgrm. of manganese per litre of water. With less than 0·5 mgrm. of manganese per litre, it may be determined by means of the tetramethyldiaminophenylmethane colour reaction, whilst quantities above 5 mgrms. per litre may be determined by treating the permanganate formed with potassium iodide and titrating the liberated iodine with thiosulphate solution, or the permanganate may be converted into manganese dioxide and the latter determined iodometrically after the addition of sodium phosphate to prevent the interference of ferric salts.—W. P. S.

Manganese in water; Colorimetric determination of small quantities of ——. H. Lührig. Chem.-Zeit., 1914, 38, 781—783.

100 c.c. of water are mixed with 3 c.c. of concentrated nitric acid and sufficient silver nitrate to precipitate the chlorides, then 3 grms. of ammonium persulphate in strong solution are added, and the liquid heated to boiling for five minutes. If manganese compounds are present the colour of permanganate is produced, and as little as 0·005 mgrm. can be detected. By comparing the colour with that given by a standard solution, the method can be made quantitative. The distilled water used must be purified by oxidation and redistillation. As a standard, permanganate solution, freshly prepared with the special distilled water and containing about 0·05 to 0·10 mgrm. per c.c., was used. The addition of too little silver nitrate hinders the formation of the colour, and the addition of too much, or too long standing, renders the liquid dark. A water containing much chlorine causes the colour to be bluer than the true violet shade; this difference can be eliminated by adding about the same quantity of common salt and a known amount of the standard manganese solution to distilled water, and using this to obtain the comparison colours. The varying depths of colour are most sharply distinguished when 100 c.c. of a water is taken containing between 0·3 and 0·6 mgrm. Mn per litre. In two series of experiments under different conditions on 50 c.c. of water containing 0·044 mgrm. Mn, the means of the amounts found were 0·0498 and 0·0483. Increasing quantities of common salt and ferrous sulphate added to the water tended to make the results too high. In tests with tap-water to which from 1—10 mgrms. Mn was added per litre, satisfactory results were obtained provided the water was not allowed to stand too long before titration.—J. H. J.

Lead-poisoning; Value and importance for the German lead industry of blood examination in ——. J. Schoenfeld. Z. angew. Chem., 1914, 27, 313—315.

"Colour" signs and hæmatoporphyrinuria are not by themselves reliable indications of lead poisoning. Examination of the blood, stained either with weak borax-methylene-blue solution, or "azure II-giemsa" solution, is the only reliable test. An alteration of the colour of the red corpuscles is to be seen before true basophilic granulation sets in. The author gives the results of his investigations among lead workers, and suggests regulations for the control of lead-working industries. The best remedy for lead poisoning is occupation in fresh dust-free air.—T. St.

Mercuric iodide; Bactericidal power of ——. H. Stassano and M. Gompel. Comptes rend., 1914, **158**, 1716—1719.

Comparative experiments with mercuric chloride, iodide, cyanide and benzoate, carried out with very dilute solutions (*N*/1000—*N*/500,000) in order to avoid the use of double salts, indicate that mercuric iodide is a much more powerful bactericide than the other salts and is about ten times as active as the chloride.—J. H. L.

Patents.

Liquids; Method of and apparatus for pasteurising ——. C. Krug, Frankfurt-on-Maine, Germany. Eng. Pat. 27,904, Dec. 4, 1913. Under Int. Conv., April 26, 1913.

In steam chambers for pasteurising liquids in bottles, compressed air is admitted through pipes so arranged that the air is heated by the steam. When the steam supply is cut off, the current of compressed air is continued in order to expel the hot air and steam from the chamber and gradually cool the bottles.—W. P. S.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

Morphine; The non-interference of ptomaines with certain tests for ——. J. Rosenbloom. J. Biol. Chem., 1914, **18**, 131—132.

The products formed during the aerobic and anaerobic putrefaction of human organs do not give a reaction with ferric chloride, nitric acid, and iodic acid, or with Fröhde's, Pellagri's, and Husemann's tests for morphine, and there was no difficulty in detecting the presence of morphine in putrefied organs removed from a body 13 months after burial. Further, the bacterial products did not give any reactions similar to those yielded by coniine, nicotine, atropine, strychnine, digitaline, veratrine, colchicine, and delphinine.—W. P. S.

Strychnine; Use of manganese carbonate for detecting traces of ——. G. Guérin. J. Pharm. Chim., 1914, **9**, 595—597.

The alkaloidal residue is dissolved in two or three drops of sulphuric acid and a few mgrms. of manganese carbonate are stirred in with a glass rod. With strychnine a blue coloration appears which slowly changes first to violet and finally to rose: 0·01 mgrm. of the alkaloid can be detected in this way.—F. Shdn.

Euquinine and aristoquinine. P. Biginelli. Annali Chim. Appl., 1914, **1**, 397—400.

Euquinine and aristoquinine are usually described respectively as the ethylcarbonate and carbonate of quinine. They are, however, not true salts of quinine, for they are unaffected even by hot caustic alkali solutions. Quinine can be recovered from them quantitatively in the form of bisulphate by boiling with dilute sulphuric acid. The compounds must be regarded as derivatives of a quinine-carbonic acid, euquinine being $C_2H_5O.CO.C_{20}H_{23}N_2O_2$, or quininecarbonic acid ethyl ester, and aristoquinine, $(C_{20}H_{23}N_2O_2)_2CO$ or carbonylquinine. True quinine carbonate $(C_{20}H_{24}N_2O_2)_2,H_2CO_3$, m. pt. 168°—169° C., was prepared by passing carbon dioxide into a solution of quinine in aqueous ether.—A. S.

Santonin [in wormseed] determination; Fromme's method of ——. C. E. Caspari. J. Amer. Pharm. Assoc., 1914, 634. Pharm. J., 1914, **38**, 819.

The finely powdered wormseed (13·0 grms.) is allowed to macerate with occasional shaking with 130 grms. of chloroform. 102·5 grms. of the liquid (=10 grms. of the drug) are drawn off and evaporated till the residue weighs 7 to 8 grms., which is then mixed with 100 grms. of 5% barium hydroxide solution and heated on the water bath till the odour of the chloroform has disappeared. The liquid is filtered through a wet filter and the insoluble matter washed twice with 10 c.c. of hot water. The filtrate and washings are acidified with 5 grms. of 25% hydrochloric acid, heated on the water bath for a few minutes, cooled, and shaken out with 20, 15, and 15 c.c. of chloroform. The extracts are filtered and evaporated to dryness. The residue is dissolved in 7·5 grms. of absolute alcohol and 42·5 grms. of hot distilled water added. The milky liquid is filtered immediately into a tared flask and the filter is washed twice with 10 grms. of 15% alcohol. After 24 hours the liquid is filtered through a tared filter, and the flask and filter washed twice with 10 grms. of the dilute alcohol. The flask and filter are then dried at 100° C. to constant weight, 0·04 grm. being added to the weight of santonin found.—F. Shdn.

Phytin; Observations concerning ——. W. Heubner. Biochem. Zeits., 1914, **64**, 409—421.

Commercial barium and sodium salts of phytic acid were found to contain 4 atoms Ba or 8 atoms Na for every 6 atoms P, and it is suggested that the sodium salt, for example, may be a di-substitution product of inositol, $(Na_2O_4P)_2PO·C_6H_{10}O_{12}·PO(PO_4Na_2)_2$. The rate of hydrolysis of phytic acid in presence of 1·5 *N* mineral acid at 37° C., is less than 1% per day, and appears to be somewhat accelerated by light. (See Plimmer and Page, this J., 1914, 660.)—J. H. L.

Sandalwood oil; Determination of santalol in ——. E. Wende. Apoth.-Zeit., 1914, **29**, 541—542.

A stoppered bottle of 100 c.c. capacity containing 5 grms. of sandalwood oil, 5 grms. of acetic anhydride and 1 grm. of finely powdered anhydrous sodium acetate is well shaken and heated in a water-oven for an hour with occasional shaking. The acetylated oil is then separated in the usual way, and 1·5—2·0 grms. are dissolved in 3 c.c. of alcohol in a 100 c.c. stoppered bottle, neutralised, and 25 c.c. of *N*/2 alcoholic potassium hydroxide solution added. The bottle is securely fastened, placed in a water oven, heated for 30 mins. after the water has begun to boil, and the excess of free alkali titrated. If *a* grms. be the weight of acetylated oil taken and *n* the number of c.c. of *N*/2 potassium hydroxide solution consumed, the percentage of santalol, S, is given by the formula: $S = \frac{11n}{a - 0·021n}$.—F. Shdn.

Oil of Chinese bitter orange [Citrus sinensis, Person]; Characters of ——. P. Fenaroli. Annali Chim. Appl., 1914, **1**, 408—412.

The Chinese bitter orange is used largely in the manufacture of preserves, and recently extraction of the oil from the outer skins has been undertaken on a commercial scale in Italy. The cultivation of this fruit is extending in Italy and the oil is likely to acquire some importance as a commercial product. The oil has the sp. gr. 0·847—0·848 at 15° C., $\alpha_D^{20} = +94·10°$ to $+95·40°$, $n_D^{17} = 1·17388$—1·47408. It dissolves in 4—4½ vols. of 90% alcohol, but is only partially soluble in 80% alcohol. When distilled at 80 mm. pressure it yielded the following fractions: 102°—104° C., 62·5% ($\alpha_D^{14} = 96·76°$); 104°—105°, 27·5% ($\alpha_D^{14} = +98·80°$); 105°—110°, 5·2% ($\alpha_D^{14} = +96·28°$); 110°—120° C., 2% ($\alpha_D^{14} = +80·64°$); residue, 2·8% ($\alpha_D^{14} = +23·40°$). Examination of the various fractions showed that the oil contains 97—98% of *d*-limonene, and small quantities of a substance of lower boiling point, probably *d*-pinene, and of ethers and aldehydes boiling much above 176° C. Citral could not be detected in the higher-boiling fractions.—A. S.

Cineol; Iodo-derivatives of ——. [*Determination of cineol.*] E. Fromm and H. Fluck. Annalen, 1914, **405**, 175—180.

On shaking cineol with a crude concentrated aqueous solution of hydriodic acid, fine dark-green crystals of a fairly stable iodine compound are obtained. Hydriodic acid containing no free iodine does not give these crystals but yields dipentene di-iodide. The crystals were found to be identical with a substance obtained by Wallach and Brass (Annalen, 1884, **225**, 300) by the action of iodine in petroleum ether on cineol and by Kraut and Wahlfors (Annalen, 1863, **129**, 295) by the action of iodine in potassium iodide on wormseed oil, and described as cineol di-iodide $(C_{10}H_{18}O_2)_2I_2$. From the elementary analyses and iodometric determinations the crystals are considered to be a double compound of cineol di-iodide and cineol hydriodide. Cineol can be determined quantitatively by adding a known excess of acidified $N/10$ iodine solution, filtering off the iodo-compound and titrating the excess of iodine with standard thiosulphate solution.—T. C.

Galangal oil; Constituents of ——. E. Fromm and H. Fluck. Annalen, 1914, **405**, 181—187.

About 1 kilo. of galangal oil was fractionally distilled. All fractions yielded only traces of substances soluble in alkalis, and the presence of eugenol, previously recorded, is doubtful. The first runnings, distilling at 157°—159° C., formed the smallest fraction and were not examined. The chief fraction distilled at 171°—173° C. and consisted largely of cineol, which was determined by means of the hydriodide of the iodo-compound and obtained pure by decomposing this compound with cold aqueous caustic soda solution (see preceding abstract). The fraction boiling at 208°—210° C. formed only 1 to 2% of the oil and its constituents could not be ascertained. Repeated fractionation gave a fraction boiling at 260°—263° C. containing two new sesquiterpenes, one boiling at 150°—155° C. at 18 mm. and giving no hydrochloride, and the second giving a hydrochloride crystallising in needles from alcohol, m. pt. 118° C. The sesquiterpene previously lescribed by Schindelmeiser (Chem.-Zeit., 1905, **29**, 308) ould not be detected. On standing, the highest boiling ractions yielded a small amount of a substance crystallising from diluto alcohol in needles, m. pt. 167° C., having he formula, $C_{15}H_{26}O$.—T. C.

inalool: Constitution of ——. P. Barbier and R. Locquin. Comptes rend., 1914, **158**, 1554—1558.

Vhen reduced by means of platinum and hydrogen at he ordinary temperature, linalool yielded a saturated terary alcohol, $(CH_3)_2 : CH{\cdot}CH_2{\cdot}CH_2{\cdot}C(OH)(CH_3){\cdot}CH_2{\cdot}CH_3$, oiling at 86°—88° C. at 10 mm., sp. gr. 0·851 at 4° C., nd $a_D = -24'$. This was readily converted by heating ith anhydrous formic acid into an unsaturated hydroarbon, b. pt. 162° C. The latter yielded methylisohexyletone when oxidised with chromic acid. Isoamylacetyl etate was hydrolysed and the ketone converted into trahydrolinalool which had the same physical characters the above tertiary alcohol but was optically inactive. he allophanate from the inactive tertiary alcohol melted 110°—111° C., whilst that from the active modiation melted at 88° C. The formula for linalool, $H_4)_2 : CH{\cdot}CH_2{\cdot}CH_2{\cdot}C(OH)(CH_3){\cdot}CH : CH_2$, proposed by mmler and Tiemann was thus confirmed.—F. Shdn.

ytosterols. Hydro-carotin. E. Beschke Ber., 1914, **47**, 1853—1856.

rrot roots (*Daucus carota*) were extracted with water, ied, and extracted with light petroleum. The residue m the latter consisting of hydro-carotin was crystallised m alcohol and melted at 135°—136° C., the yield being 1%. By treatment of the bromine addition products the acetyl compound, it was found that hydro-carotin isisted of 90% of sitosterol, m. pt. 136°—137° C., and % of stigmasterol, m. pt. 170° C.—F. Shdn.

nethylglyoxime: The preparation of —— *without the se of hydroxylamine.* J. M. Johlin, jun. J. Amer. hem. Soc., 1914, **36**, 1218—1221.

Nitrosomethylethyl ketone (diacetyl monoxime) ociates, under the influence of strong acids, in part east, into diacetyl and hydroxylamine, which recom under suitable conditions to give the less soluble ime. 850 c.c. of methylethyl ketone were treated, rding to the method of Diels and Stephan (Ber., 1907, **40** 4337) for the preparation of diacetyl, with 30 c.c. of hydrochloric acid and 1000 c.c. of amyl nitrite. The resulting mixture was shaken with sodium hydroxide, and the alkaline layer acidified with 25% sulphuric acid. After standing 24—36 hours 50—60 grms. of dimethylglyoxime had crystallised out and the oily layer had almost disappeared. The mother liquors were further treated for the recovery of diacetyl according to the prescribed method.—G. F. M.

1.5-*Diketones; Action of sodamide on* ——. E. Bauer. Comptes rend., 1914, **158**, 1680—1683.

The author has already shown (Comptes rend., 1913, **156**, 1470, 1684) that sodamide converts 1.6- and 1.7-diketones into cyclopentane and cyclohexane derivatives. With 1.5-diketones it forms disodium compounds which interact with methyl iodide and yield dimethyl derivatives of the original diketones. Dibenzoylpropane, for example, yields amongst other products dimethyldibenzoylpropane, whereas benzaldiacetophenone yields 83% of a mixture of ethylphenylketone and benzalpropiophenone, both of which are doubtless produced by fission of the dimethylbenzaldiacetophenone first formed.—J. H. L.

Acetone; Equilibria in the systems, water, ——, *and inorganic salts.* G. B. Frankforter and L. Cohen. J. Amer. Chem. Soc., 1914, **36**, 1103—1134.

An investigation of the equilibria in the four systems: water, acetone, and potassium fluoride; water, acetone, and potassium carbonate; water, acetone, and calcium chloride; water, acetone, and sodium chloride, has led to the following conclusions. Potassium fluoride is as efficient as potassium carbonate for salting out acetone, and acts more rapidly, giving cleaner cut separations. The saturated solution of potassium fluoride dehydrates to 98% of acetone, that of potassium carbonate to 96·5%, and of calcium chloride to 98·4%. The use of calcium chloride entails loss of acetone since the aqueous solution retains 23%, whilst in the saturated solutions of the other substances acetone is practically insoluble. Sodium chloride is the least satisfactory substance for salting out acetone as it retains 21% and dehydrates only to 85·8%. The lower critical solution temperatures for a series of solutions are given: no upper critical solution temperatures could be observed. A method for the quantitative determination of acetone in aqueous solution, provided no other substance is present, depends on the fact that for every mixture of acetone and water there is a corresponding amount of potassium fluoride required to produce the just homogeneous mixture. This amount is determined experimentally, and from the table for the binodal curve of the system water, acetone, potassium fluoride, the corresponding amount of acetone is obtained. —G. F. M.

Acetaldehyde from acetone; Quantitative separation of ——, E. Hägglund. Z. anal. Chem., 1914, **53**, 433—439.

On heating in the water-bath a mixture of 15 c.c. of water, 50 c.c. of $N/2$ silver nitrate, 9 c.c. of $N/1$ sodium hydroxide, 25 c.c. of ammonia of sp. gr. 0·92, and 10 c.c. of a solution containing not more than 2% of acetaldehyde, the whole contained in a closely stoppered bottle, the aldehyde is oxidised and may be estimated by titrating the unreduced silver in an aliquot portion of the clear liquid. Acetone and acetaldehyde may be determined together by adding excess of bisulphite and titrating the excess in alkaline solution with $N/10$ iodine. The acetaldehyde having previously been determined as described above, the acetone is obtained by difference.—O. E. M.

Carbon dioxide snow; Substitute for —— [*Trichloroacetic acid*]. E. Sommer. Schweiz. Rundsch. Med., Jan. 10, 1914. Pharm. J., 1914, **38**, 786.

The use of trichloroacetic acid in the solid form or in aqueous solution is recommended in place of carbon dioxide snow in dermatology.—F. Shdn.

PATENT.

Orthovanadic esters and their solutions ; Preparation of ——. L. Hess. Ger. Pat. 273,220. March 28, 1913.

VANADIUM pentoxide dissolves in primary, secondary, tertiary mono- or polyhydric alcohols with formation of esters of the type, R_3VO_4. Vanadic acid ethyl ester, $(C_2H_5)_3VO_4$, is a liquid of faint yellow colour, sp. gr. 1·167 at 15° C., b. pt. 108° C. at 26 mm. The isopropyl ester is a yellowish liquid boiling at 124° C. at 21 mm. The amyl ester boils at 161° C. at 19 mm. and has the sp. gr. 0·993 at 15° C.—A. S.

XXII.—EXPLOSIVES; MATCHES.

Explosion at the works of the Aktien-Gesellschaft für Anilinfabrikation, Rummelsberg, Germany. Chem. Ind., 1914, **37**, 337—342. (See also this J., 1914, 376.)

THE Commission appointed to enquire into this accident considered the following suggestions among others: That it was due to the admission of large quantities of acid, cooled below the reaction-temperature, to the nitrating vessel, followed by an uncontrollable reaction on a rise of temperature; and that ignition of the mixture of benzene vapour and air was due to direct action between benzene and nitric acid at 100°—170° C. An apparatus was described by Neumann in which the quantities reacting are small and are rapidly removed: the liquids flow through the annulus between an inner rotating and an outer fixed cylinder, both carrying blades and cooled or heated, locally or throughout, as required. Ter Meer's apparatus (Ger. Pat. 228,544; this J., 1911, 373) was also described. Further suggestions were: the interlocking of cocks and striking gear, the provision of a pendulum in the liquid, with an exterior indicator to show that the liquid is in motion, the use of a cast iron fume pipe leading to a separate tower, and of a stronger cover.—O. E. M.

Perchlorates of aromatic amines. R. Spallino. Annali Chim. Appl., 1914, **1**, 435—440.

THE perchlorates of aniline, *p*-nitroaniline, *p*- and *m*-phenylenediamine were prepared by double decomposition of barium perchlorate and the sulphate of the amino-compound, the solution, after filtering off the barium sulphate, being evaporated over a direct flame to incipient crystallisation. They were stable on exposure to air and light, and began to decompose, without exploding, only at 200°—220° C. when heated. When wrapped in tinfoil and submitted to the falling weight test, using 0·1 grm. of substance and a weight of 2 kilos., the fall required to produce an explosion was 70—75 cm. for the perchlorate of aniline, 80 cm. for that of *p*-nitroaniline, 55 cm. for that of *p*-phenylenediamine, and 50 cm. for that of *m*-phenylenediamine, as compared with 73—75 cm. for picric acid.—A. S.

Waste product from the manufacture of trinitrotoluene. Molinari and Giua. *See* III.

PATENT.

Explosives. F. L. Nathan, W. Rintoul, and F. Baker, Ardeer, Scotland. Eng. Pats. 4940 and 4941, Feb. 26, 1913. (See also Eng. Pats. 12,743 to 12,746 of 1912; this J., 1913, 991.)

A PROPELLANT is obtained by incorporating a gelatinising agent, which remains in the powder, and a stabiliser, both freely soluble in nitroglycerin, with nitroglycerin and nitrocellulose, without the use of a volatile solvent. The stabiliser may have little or no gelatinising effect, and is used with a substance of relatively high gelatinising action. Amyl or ethyl phthalate, mono-, di-, or triacetin, or a nitro-derivative of an aromatic hydrocarbon, such as di- or trinitrotoluene, is used as a gelatinising agent, with or without methyl- or ethyl-β-naphthyl ether, phenylbenzyl ether or phenanthrene, as stabiliser. Such a propellant contains about 40% of nitroglycerin, 50 of soluble nitrocellulose, and 10 of gelatiniser and stabiliser together, and may be made by bringing the ingredients together suspended in water, removing the excess of water, and gelatinising at 50°—70° C.—O. E. M.

XXIII.—ANALYTICAL PROCESSES.

Mercury resistance thermometer as a reproducible empirical temperature scale. W. Jaeger and H. von Steinwehr. Ann. der Physik, 1914, [4], **43**, 1165—1185. Chem. Zentr., 1914, **1**, 1985.

THE thermometer used by the authors consists of a quartz capillary about 1 m. long and 0·9 sq. mm. cross-section, bent into W-form and connected at the ends with somewhat wider quartz tubes to receive the platinum electrodes. Accurate measurements showed that when pure mercury was used, the calculated and observed resistances at different temperatures were identical within the limits of accuracy of the measurements, so that only one fixed point (*e.g.*, 0° C.) is necessary for calibrating the instrument throughout the whole range—30° to + 300° C.—A. S.

Copper and tin groups ; New procedure for the separation of the ——. L. J. Curtman and J. K. Marcus. J. Amer. Chem. Soc., 1914, **33**, 1093—1103.

THE objectionable features of the ammonium polysulphid and sodium hydroxide methods for the separation of th copper and tin groups may be avoided by a scheme o analysis of which the following are the principal points Preliminary precipitation of the alkaline-earth metal and some of the lead from the filtrate of group I. b sulphuric acid and analysis for these metals by the metho of Curtman and Frankel (this J., 1912, 1203). Treatmen of the filtrate from the precipitation of the alkaline earth metals with sulphur dioxide, before passing i hydrogen sulphide, to oxidise stannous tin and reduc quinquevalent arsenic. The complete separation of th sulphides of the divisions of group II. by means of 25° potassium hydroxide solution.—G. F. M.

Potassium ; New method of determining ——. F. Marshal Chem.-Zeit., 1914, **38**, 585—587, 615—616.

THE solution containing only the alkalis as chlorid (about 0·05 grm. of K_2O) is evaporated on the water-bat the residue dissolved in the smallest possible quant of water, and the solution treated in the cold with excess (20 c.c.) of a 2% alcoholic solution of tartaric ac which has been stirred at intervals for several days wi solid potassium bitartrate and then filtered. After t precipitation from 10 to 20 c.c. of 96% alcohol saturat with potassium bitartrate are added, and the liquid boil for about 10 mins. on the water-bath. It is then l (with frequent stirring) for 24 hours, after which t precipitate is collected in a weighed Gooch crucib washed first with the saturated alcohol and then w pure 96% alcohol, dried at 80° C. and weighed potassium bitartrate. The results are in close agreem with those given by the platinum chloride method. —C. A. M

Nickel ; Determination of —— by dimethylglyoxime. Brunck. Z. angew. Chem., 1914, **27**, 315—318. (this J., 1907, 643.)

To ensure the complete precipitation of the nickel af adding the dimethylglyoxime, the solution should allowed to stand for one hour before filtering. Ignition of the precipitate to oxide gives accurate results if proper precautions are taken (this J., 1908, 812). When a solution of ferric and cobalt salts containing tartaric acid and dimethylglyoxime is made ammoniacal, an insoluble iron-cobalt compound of dimethylglyoxime is precipitated, but if the iron is present in the ferrous condition only, no precipitate is formed. Hence to determine nickel in a steel containing cobalt it is necessary first to bring and keep all the iron in the ferrous condition. This is conveniently accomplished with an excess of sulphurous acid. Dimethylglyoxime then gives a quantitative precipitation of the nickel, the iron and cobalt being left wholly in solution.—T. St.

Tellurium; Gravimetric determination of ——. A. Gutbier and S. Huber. Z. anal. Chem., 1914, **53**, 430—433.

THE method of Lenher and Homberger (J. Amer. Chem. Soc., 1908, **30**, 387) is convenient and accurate. To the boiling solution of the sample in 10% hydrochloric acid are added 15 c.c. of saturated sulphur dioxide solution, 10 c.c. of 15% hydrazine hydrochloride solution, and a further 25 c.c. of the sulphur dioxide solution. The precipitated elementary tellurium settles in the boiling liquid. and is washed, dried at 100°—105° C., and weighed. The use of 35—40 c.c. of sulphur dioxide solution instead of 25 c.c. is suggested.—O. E. M.

Iodine; Determination of —— especially in organic substances. R. Grützner. Chem.-Zeit., 1914, **38**, 769—770.

ORGANIC matter is destroyed by fusing with pure sodium hydroxide, adding sodium peroxide, barium peroxide, or a readily fusible mixture of alkali and nitre, and heating to dull redness (excess of the oxidiser may be removed by adding charcoal after cooling and again heating); the melt is either dissolved in water, and the solution diluted, and filtered, or (with barium peroxide) it is treated with boiling water, then with carbon dioxide and sodium sulphate, and the precipitate well washed with water containing sodium sulphate. The solution is treated by a modification of the method of Bernier and Péron (this J., 1911, 359), iodide being oxidised to iodate by boiling with permanganate, the mixture carefully acidified with sulphuric acid, again boiled, cooled, made alkaline with solid sodium carbonate, boiled with alcohol, filtered, and the residue washed, whilst hot, with water containing alcohol. Excess of alcohol is boiled off, the solution made acid to litmus with a mixture of phosphoric and sulphuric acids (prepared by treating a hot mixture of 3 vols. of phosphoric acid, 1 : 4, and 2 vols. of sulphuric acid, 1 : 4, with $N/10$ permanganate in slight excess, and decolorising with $N/10$ oxalic acid), and, after adding solid ammonium sulphate, again boiled. The cooled solution is made acid to Congo red, treated with potassium iodide, and the liberated iodine titrated with thiosulphate. One-sixth of the iodine found represents that originally present. The method is accurate in presence of other halogens and cyanides.
—F. SODN.

Fluorine; Greef's method for the volumetric determination of ——. I. Bellucci. Annali Chim. Appl., 1914, **1**, 441—446.

THE author has found that the method recommended by Greef (this J., 1913, 992), namely titration with ferric chloride solution of a neutral solution of alkali fluoride to which sodium chloride and potassium thiocyanate have been added, gives satisfactory results when the quantity of fluoride is about 0·2 grm.; the results are much too low, however, when the quantity of fluoride is less than 0·1 grm. The variable results appear to be due to the influence of the sodium chloride. Using 25 c.c. of solution, the most satisfactory results were obtained with 10—20 grms. of sodium chloride for 0·2 grm. of sodium fluoride, with 2 grms. for 0·04 grm., and with 1 grm. for 0·02 grm. of fluoride.—A. S.

Phosphoric acid; Determination of inorganic —— in presence of phosphoric acid esters. W. Heubner. Biochem. Zeits., 1914, **64**, 401—408.

FROM solutions containing 4% of concentrated sulphuric acid by volume, and 15% of ammonium nitrate, inorganic phosphoric acid can be quantitatively precipitated as ammonium phosphomolybdate of normal composition within 6 hours at 37° C. The precipitation is not affected by small quantities of phytin; and provided the phytin-phosphorus does not exceed in amount six times the inorganic phosphorus, and the concentration of the former does not exceed 0·05%, at least ¾ of the inorganic phosphorus present can be found by one precipitation as phosphomolybdate, followed by titration by Neumann's method (cp. Plimmer and Page, this J., 1914, 660). The disturbing influence of glycerophosphoric acid is less than that of phytin.—J. H. L.

Phytin; Determination of —— by titration. W. Heubner and H. Stadler. Biochem. Zeits., 1914, **64**, 422—437.

IN solutions containing 0·6% of free hydrochloric acid and 0·03% of ammonium thiocyanate, phytin may be determined by titration with ferric chloride solutions containing 0·05—0·2% of iron and 0·6% of free hydrochloric acid. Under these conditions ferric phosphate is not precipitated, but phytic acid is converted into an insoluble salt. The titration is complete when the liquid assumes a faint red colour which does not fade within 5 mins. One mgrm. of iron corresponds to 1·19 mgrm. of phosphorus present as phytin. The titration is not affected by the presence of a moderate excess of inorganic phosphates or glycerophosphate.—J. H. L.

Sources of error in the analysis of basic slag. Popp. *See* XVI.

A comparison of neutral ammonium citrate with sodium citrate and $N/10$ citric acid. Rudnick and others. *See* XVI.

Modification of the double polarisation (Clerget-Herzfeld) method of determining sucrose in (beet) molasses. Stanek. *See* XVII.

Action of formaldehyde in presence of sulphuric acid. Buraczewski and Matejko. *See* XVIII.

A comparison of the microscopical method and the plate method of counting bacteria in milk. Brew. *See* XIXa.

Determination of the viscosity of milk as a means of detecting addition of water. Kooper. *See* XIXa.

Determination of crude fibre [*in grain, bran, etc.*]. Stiegler. *See* XIXa.

Separation and determination of sugars in gingerbread and similar products. König and Burberg. *See* XIXa.

Determination of hardness of water. Winkler. *See* XIXb.

Manganese in water, its detection and determination. Tillmans and Mildner. *See* XIXb.

Colorimetric determination of small quantities of manganese in water. Lührig. *See* XIXb.

Non-interference of ptomaines with certain tests for morphine. Rosenbloom. *See* XX.

Use of manganese carbonate for detecting traces of strychnine. Guérin. *See* XX.

Fromme's method of santonin determination [*in wormseed*]. Caspari. *See* XX.

Determination of santalol in sandalwood oil. Wende. *See* XX.

Iodo-derivatives of cineol. [*Determination of cineol*]. Fromm and Fluck. *See* XX.

Equilibria in the systems, water, acetone and inorganic salts. Frankforter and Cohen. *See* XX.

Quantitative separation of acetaldehyde from acetone. Hägglund. *See* XX.

Patents.

Gas analysis apparatus. J. G. Taplay and J. Abady, London. Eng. Pat. 17,676, Aug. 1, 1913.

Combustion of the non-absorbable constituents (hydrogen and methane) of a gas mixture such as coal gas or producer gas, is effected in a vessel containing a tube or rod made from copper oxide and a suitable matrix such as china clay. The combustion products are displaced by mercury instead of by nitrogen or carbon dioxide as is done when the copper oxide is used in granular form. The oxide is reduced to cuprous oxide and no metallic copper is formed, so that no amalgamation can occur.—A. T. L.

Sampling liquids ; Apparatus for ——. R. L. Chambers, Broxburn, Scotland. Eng. Pat. 17,828, Aug. 5, 1913.

The liquid flows from a constant-level tank into an adjustable tilting trough which, when full, delivers partly to waste and partly into one of a circle of bottles moved round by a step-by-step device actuated by the trough. —O. E. M.

XXIV.—MISCELLANEOUS ABSTRACTS.

Fluorine in mineral waters. A. Gautier and P. Clausmann. Comptes rend., 1914, **158**, 1631—1640.

All mineral waters contain fluorine, the amount found in a number of waters from different sources ranging from 0·15 to 6·32 mgrms. per litre. The fluorine-content appears to bear no relation to the temperature of the water. The ratio, fluorine : saline residue, is highest in sulphurous waters. Sea water contains about 0·3 mgrms. of fluorine per litre.—L. E.

Light; Chemical action of ——. (*XXX.*) G. Ciamician and P. Silber. Ber., 1914, **47**, 1806—1814.

The production of an addition-compound of two mols. of benzaldehyde and one of benzophenone, by the action of light on a mixture of these compounds, is confirmed. A polymeride of benzaldehyde (Paternò, Gaz. chim. ital., 1914, **44**, I, 153) is not formed. Acetophenone and ethyl alcohol yield, in addition to ordinary acetophenonepinacone (this J., 1901, 844), its optical isomeride of m. p. 86°—87° C. Benzophenone and acetophenone, with isopropyl alcohol, give respectively benzopinacone and the two acetophenones together with acetone. With ethyl alcohol ethylphenylketone behaves similarly to acetophenone, giving ethylphenylpinacone and its optical isomeride. Acetophenone and benzyl alcohol yield acetophenonepinacone ; from the residue, on benzoylation, dibenzoylhydrobenzoïn and the monobenzoyl derivative of diphenylmethylethyleneglycol are obtained.—O. E. M.

Books Received.

Electric Furnaces for Making Iron and Steel. By D. A. Lyon and R. M. Keeney. Department of the Interior. Bureau of Mines. Bull. 67. Govt. Printing Office, Washington. 1914. Price 20c.

Volume ($9\frac{1}{8}$ by $5\frac{7}{8}$ in.), containing 133 pages of subject matter with 36 illustrations, a selected bibliography, a list of publications on Mining and Mineral technology, and an alphabetical index.

The text is classified as follows :—I. The electric furnace in pig-iron manufacture. II. The electric furnace in steel manufacture.

Geschichte des Elektroeisens, mit besonderer Berücksichtigung der zu seiner Erzeugung bestimmten elektrischen Oefen. Von Dr. techn. Oswald Meyer. Julius Springer's Verlag. Berlin. 1914. Price M. 7 ; bound M. 8.

Volume ($9\frac{1}{2}$ by $6\frac{1}{2}$ ins.), containing 182 pages of subject matter, with 206 illustrations, a bibliography, and alphabetical index of names. The text is classified under the heads : I. History of the electrical preparation of iron and of the furnaces designed for the purpose. II. The present forms of furnaces and of those in course of construction, for the preparation of iron and steel. III. Classification and general review of the known systems of electric furnaces for iron and steel. IV. The revolving electro-furnace of Schatzl-Krieger.

Enzyklopädie der technischen Chemie. Unter Mitwirkung von Fachgenossen. Herausgegeben von Professor Dr. Fritz Ullmann. Erster Band. Urban and Schwarzenberg. Berlin N. Friedrichstrasse, 105b, and Vienna, 1, Maximilianstrasse 4. 1914. Williams and Norgate, 14, Henrietta Street, Covent Garden, London, W.C. Price £1 12s. net.

Volume ($10\frac{5}{8}$ by $7\frac{5}{8}$ ins.), containing 795 pages of subject matter with 295 illustrations, and an alphabetical index of subjects. There is a preface, list of co-workers with the editor, Dr. Ullmann, and a table of abbreviations and their meaning.

The subjects begin in Vol. I. with "Abanon" and end with "Äthylalkohol" (p. 636—795). At the close of each subject under the title "Literatur," is given a list with references, of all the works, etc., the contents o which are utilised.

PROCEEDINGS

OF THE

THIRTY-THIRD ANNUAL MEETING.

NOTTINGHAM.

WEDNESDAY, JULY 15TH, 1914.

The Thirty-Third Annual General Meeting of the ty was held in the large lecture theatre of University llege, Nottingham, on Wednesday, July 15th, 1914, the resident, Dr. Rudolph Messel, F.R.S., in the chair.

The Mayor of Nottingham, Mr. FREDERICK BALL, ttended to offer a welcome to the members on behalf of he City. He said that as the representative of a city hose past was crowded with historic events of national nportance, and whose Castle had been the home of Kings nd Parliaments; as the representative of a city, the terest of which was bound up with the industrial and mmercial development of our country, he had the ivilege and honour to give them a cordial welcome, and hope that their deliberations might be profitable to dustry and manufactures. Many people had formed an inion that this country had not made the advance in emical science and manufacture attained by others. If ere were any truth in such an opinion he trusted that s Society would see to it that this stigma was removed, d that British manufacturers would have as much aid m chemical science as their competitors abroad. King rge, when Prince of Wales, on his return from his npire tour, and speaking at the Guildhall on December , 1901, had said "Wake up, England!" He was sure Society was alive to the important part it could play giving effect to that injunction. The aid chemical ence could render to the local trades of bleaching, eing and dressing of lace and hosiery fabric, was beyond ception. The municipality of Notttingham was alive the importance of imparting knowledge of chemical nce as applied to industry and had, through the Uni- ity College, given every facility for its study, especially onnection with the staple trades.

The PRESIDENT, in acknowledging the welcome, desired behalf of the Society of Chemical Industry to offer their dial thanks for the hearty reception which the Mayor l given to them. The Mayor was perfectly right to ind them of the words of the present King, when, as nce of Wales in 1901, he said "Wake up, England!"; was also right to expect that the Society should do great ngs for chemistry and industry. As far as chemical ustry was concerned, His Majesty's words held as good lay as they did in 1901. It was true that they had de considerable strides in many directions, especially his district; still they had a great deal of leeway to ke up. It was curious that many inventions which had origin here in England seemed, after all, not to have n worked in this country as they ought to have been. tish manufacturers ought to take up new industries. a case in point, he referred to the synthetic production mmonia, the invention of Prof. Haber; he did not see this could not be made one of the great industries of country, where the facilities for carrying it on were al to those in Germany. He regretted, however, to that there was no indication of any intention to take p in this country. It was not only a case of "Wake England," but of "Wake up, masters," to whom he ld say: "Be less conservative, and see that you take intage of everything that science offers and that energy ccomplish."

APPOINTMENT OF SCRUTATORS.

n the motion of Mr. J. T. Wood, seconded by Prof. . Messrs. T. D. Morson and J. P. Bowley were inted scrutators.

RESIGNATION OF THE EDITOR.

e PRESIDENT said that since the Report of Council drafted by the Council he had received a letter from Editor of the Journal, who stated that, being now in his 70th year, he desired, owing to failing health and strength, to be relieved from his duties. The Council could do no other than accept the resignation with great regret and appreciation of over 33 years' faithful service. The Council desired to bring this before the Annual Meeting so that they might show their concurrence in its statement of regret and appreciation of the services of the Editor.

The meeting unanimously agreed.

REPORT OF COUNCIL.

The Secretary read the annual report, which was adopted on the motion of Professor A. G. Green, seconded by Mr. R. B. Batty, as follows:—

The number of members now on the register is 4142.

The losses by death amount to 35, viz.:—Frank Baker, W. P. Bloxam, Dr. E. A. Byrnes, M. Bythway, C. C. Connor, L. M. Denne, Daniel Drew, Prof. R. Kennedy Duncan, W. J. Evans, Walther Feld, Herman Frasch, E. R. Gabbett, Dr. John Gibson, Wm. Hammersley, R. C. Heath, W. D. Howard, H. Howell, C. C. Hutchinson, Dr. J. Lewkowitsch, John Macallan, D. McKechnie, Dr. Hugh Marshall, R. C. Menzies, Jas. Pass, H. T. Penterman, W. Pethybridge, H. Pocklington, F. L. Senior, W. T. Skaife, E. S. Sperry, Jos. Stirk, Sir Joseph Swan, F.R.S., Dr. W. E. Tetlow, Jos. W. Thomas, and G. C. Vogel.

Four Ordinary Members retire from the Council, and to fill the vacancies thus created, seven nominations have been received, one of which was invalid. A ballot will therefore be taken.

The following Chairmen of Local Sections retire, viz.:—Prof. R. F. Ruttan (Canada), Mr. T. W. Lovibond (Newcastle), Sir John Turney (Nottingham), Dr. Thomas Ewan (Scotland), Mr. Loxley Meggitt (Sydney), and Mr. George Ward (Yorkshire). The following have been elected to succeed them:—Prof. J. W. Bain, Dr. F. C. Garrett, Mr. John White, Mr. Robt. Hamilton, Prof. C. E. Fawsitt, and Mr. F. W. Richardson. The following Hon. Local Secretaries retire, viz.:—Mr. J. R. Coste (London), Dr. F. C. Garrett (Newcastle), and Dr. H. Sand (Nottingham), and are succeeded by Mr. T. D. Morson, Mr. E. F. Hooper, and Mr. J. M. Wilkie. Mr. W. H. Coleman (Manchester) was succeeded by Mr. L. E. Vlies soon after the last annual meeting. The Council desires to express its thanks to the retiring Chairman and Secretaries for their services to the Society.

The Balance Sheet and Annual Statement of Account, which has already appeared in the June 30th number of the Journal, will be laid before the meeting.

The Society's Medal has been awarded to the Rt. Hon. Sir Henry Roscoe, LL.D., F.R.S., for his services to science, education, and to the Society.

At the close of last year, our President, Sir William Crookes, was elected President of the Royal Society, and consequently relinquished his office in this Society. Dr. Rudolph Messel, who had but recently resumed his former post of Hon. Foreign Secretary on the death of Dr. Lewkowitsch, consented to be nominated President for the remainder of the term, and the Society is deeply indebted to him for his aid in this emergency. Sir William Crookes continues to take the closest interest in the Society's affairs, and now becomes a Vice-President.

The Journal in 1913 contained 1172 pages of text as compared with 1204 pages in 1912. Books received for notice or review will in future become the property of the Society, and add to the usefulness of the Library.

Dr. Messel, who represents the Society on the governing body of the Imperial College of Science and Technology, has been instrumental in securing the establishment of full Professorships both for Organic and for Physical Chemistry. He also strongly supports the movement in favour of the complete independence of the College.

The Council has accepted an invitation to hold the next Annual General Meeting of the Society in Manchester in September, 1915. The British Association meets there about the same time, and special arrangements are being made for giving facilities to members of this Society who attend the meeting. The Council is giving serious consideration to proposals for adding to the scientific value and interest of Annual Meetings by the addition of conferences on matters closely allied to the interests of Chemical Industry.

The Council nominated delegates to take part in a deputation to the President of the Board of Trade with regard to amendment of the Patent Act.

A Committee has been appointed to report to the Council on means for increasing the membership and usefulness of the Society, and several valuable suggestions have been received which are still under consideration.

A letter has been received from Mr. Watson Smith, stating that, being now in his 70th year, he desires to be relieved of his duties, owing to failing health and strength. The Council can only accept the resignation with great regret and with appreciation of over 33 years' faithful service.

TREASURER'S REPORT.

Mr. TYRER said that it had been an uneventful year so far as finance was concerned. The only item to which attention should be drawn was that, in common with commercial and financial affairs generally, there had been a depreciation in gilt-edged investments. Of investments amounting to the very respectable sum of £19,648 17s. 1d., the market value on December 31st was £17,349 18s. 5d. But one thing had to be remembered, namely, that the dividends were the same. The Stock Exchange latest records showed them to be better off on this statement by some £300 or £400 than they were in other years. Investments had appreciated rather than depreciated, even to that small extent. General expenses were much the same as in 1912 and 1911. Subscriptions were less by £102 11s. and advertisements less by £32 19s. 6d. That was not very serious, but from a business point of view the result ought to be better having regard to the character and large circulation of the Journal. On the other hand, sales of Journals had increased £88 14s. 2d., making a total of £867 6s. 6d.—a very respectable sum. There was a large stock of collective and decennial indexes which were very valuable and which they would be pleasde to see sold. Expenditure was less in some directions. They must not be misled by the £1285 3s. 11d. stated as excess of income over expenditure. That included interest on their savings and certain items which had to go to capital account. The accounts had been carefully kept, and the auditors had been particularly inquisitive before they had attached the usual professional certificate.

Mr. WALTER F. REID moved a hearty vote of thanks to the treasurer. The work that Mr. Tyrer placed before them in such detail and order took much valuable time. The Society knew no better friend than Mr. Tyrer had been from the commencement.

Mr. N. H. MARTIN seconded the resolution, remarking that Mr. Tyrer had brought to bear on his office the same conspicuous ability which had marked the other departments of his work.

The resolution was carried, and Mr. Tyrer, in acknowledging it, said that so long as he had health and strength and the Council would submit his name for their approval as treasurer, so long would he be pleased to hold the office.

The PRESIDENT said the meeting in Nottingham had promised to be one of the most illustrious ever held by the Society. They had expected Sir William Crookes and Sir Henry Roscoe to be present. Both were octogenarians, Sir William Crookes being 82, and Sir Henry Roscoe in his 82nd year. At the last moment neither of those gentlemen was able to come on account of ill health. All knew, of course, that Sir William Crookes was his predecessor in office, being elected last autumn, but he had very soon to retire because a great honour was done to him and through him to their Society, by his being elected President of the Royal Society—the greatest scientific honour in this country, and it was an unwritten law of the Royal Society that its President should hold no similar office simultaneously. The Royal Society had only had two chemical Presidents in a century, the first one being Sir Humphry Davy and the second their worthy President, Sir William Crookes.

PRESIDENTIAL ADDRESS.

BY SIR WILLIAM CROOKES, O.M., PRES. R.S.

In the absence of Sir William Crookes his address was read by the President, as follows (omitting the references to himself) :—

I fear that you may feel a little ennuied at being calle upon to listen to a Presidential Address delivered by on who no longer has the honour of being your Presiden But I cannot forego the opportunity of expressing m regret at being compelled to resign my position. M election to the Presidency of the Royal Society mak it impossible for me to continue to hold the office, but m interest in the Society of Chemical Industry, of which th Nottingham section is so vigorous and flourishing a branc can suffer no diminution. My regret at parting is great tempered by the reflection that in Dr. Messel, who h consented to step into the gap, the Society will have President of pre-eminent suitability and unrivalled quali cations. There is little need for me to remind you th Dr. Messel's knowledge of Industrial Chemistry and h close connection and acquaintance with foreign manufa turing practice will be of great value to English Chemist His work on the industrial applications of Catalytic pr cesses has brought him world-wide fame, and our Socie is fortunate in having a man of such eminence at the he of its affairs. I must congratulate you heartily upon t energy and enterprise displayed by your Members, a upon the success of the work accomplished. Techni chemistry makes great strides. The past year has se the publication of results which, although perhaps r sensational enough to stir public imagination, nor intrin cally important enough to be described as epoch-maki are a sufficient tribute to the steady industry of inves gators, to their resource in overcoming difficulties, a their acumen in elucidating the causal relations of so particularly interesting phenomena.

Foremost I must mention Haber's process for t production of ammonia. Ammonium sulphate is n synthesised by the Badische Company, which is about enlarge their plant by the end of 1915 to a capacity 130,000 tons per annum. The catalyst osmium has b replaced, first by uranium, later on by Fe_2O_3. T investigation of the process has shown that the lat catalyst is made more active by the addition of cert substances, *e.g.*, oxides, hydroxides, and salts of all metals, while other substances, such as arsenic, act specific poisons towards ammonia catalysts.

The demand for nitrogenous fertilisers steadily advan There is also an increasing demand for nitrogenous prod for industrial purposes, concentrated nitric acid being of the most important of these products. The N wegian Hydroelectric Nitrogen Company, Limited, am others, have worked out a simple method of obtai dilute nitric acid by the oxidation of atmospheric nitro and then concentrating the dilute acid by making of the hot gases of the furnaces. The concentrated can thus be very cheaply obtained. The Norwe Company find that the pure acid can be transporte aluminium tanks. A steamer equipped with alumin tanks for 40 tons is already in regular service betw Notodden and Eugene on the Christianiafiord, and de are in progress for 600 to 700 tons tank steamers for reg service to England and the Continent. The ou of the Company's work at Rjukau and Notodden now reached—

80,000 to 90,000 tons of nitrate of lime,
10,000 tons of nitrite of soda,
5,000 to 6,000 tons of refined nitrate of soda,
15,000 tons of nitrate of ammonia.

The work of Dr. E. J. Russell and others on the a of antiseptics on soil in increasing the growth of has led to deeply important results. The anom effects of the partial sterilisation of the soil in ca first a fall and then a rapid rise in the number of bac were first observed. Further study showed that increased productiveness of partially sterilised soil i to the increased production of ammonia, and tha increase in bacteria is the result of an improve of the soil as a medium for bacterial growth. the experiments Dr. Russell concludes that ord soil contains a factor which limits the bacterial popul and prevents its reaching its maximum. The searc this soil organism revealed the presence of many prot now being examined from a zoological point of The fact that the detrimental organisms are more killed than the useful organisms explains many parad esults—such as the ultimately beneficial influence on roductiveness of long-continued frosts and droughts, hich are harmful to organisms. The "sickness" of eenhouse soil has been investigated; it is found that it ay be ascribed to two causes—an accumulation of pests ad an abnormal development of factors detrimental bacteria. Methods are now in progress for the partial erilisation of the soil on a large scale. The action of fferent antiseptics has been studied and interesting nclusions drawn from the work. It is found that there a decided difference in the action of different antiseptics; ly actual trial will decide which may be best in special ses. Generally speaking formaldehyde and pyridine e the most useful for sick soils; cresol, phenol, etc., ming next, while the higher homologues of benzene e the least effective. None of these, however, answers as ll as steam—the most efficient of all sterilisers.

A remarkable achievement in technology is due to a mber of our Society who recently died. I refer to Frasch—to whom the Society's Perkin Medal was arded in 1912. Frasch successfully solved the blem of the extraction of sulphur from the deeply ried deposits of Louisiana. He conceived the idea melting the deposit *in situ* by means of superheated am, and forcing the molten sulphur to the earth's face through an inner tube. The process has worked isfactorily and large quantities of sulphur are thus racted.

An interesting modern process is that of Dr. Walther d, whose death in his prime is a severe blow to science. strenuous worker of great orginality, Feld has iched technology with many discoveries; the most ortant relates to the preparation of ammonium hate direct from crude coal-gas. The problem of the isation of the sulphur of the crude gas has thus been pletely solved by a particularly neat and ingenious hod. Using ammonium polythionate, ultimately aining ammonium sulphate, sulphur, and sulphurous , the two latter are again utilised in the process, le the ammonium sulphate is obtained by evaporating solution. The practical value of a process in which moaium sulphate is obtained without the use of sulric acid is obvious. The researches of Feld in working the details of this method also throw light upon y interesting scientific questions.

nother method of fixing nitrogen by utilising the har of coal is that of K. Burkheiser. In this process iron ore is used to absorb the sulphuretted hydrogen, the sulphurous acid produced from it is used for formation of a mixture of ammonium sulphate and hite. The process is working at Flemalle Grande, Liège, in Belgium, and is giving satisfactory results.

cent work on the synthesis of Rubber has attracted h attention, and notable advances have been made. ong ago as 1882 Tilden noticed that isoprene is cond into rubber by certain chemical reagents; ten s later he showed that the synthetic product obtained isoprene is capable of vulcanisation. Subsequent led to the recognition of the fact that most subes containing a conjugated double linking tend to nerise, the polymers ranging from sticky substances igh well-defined rubbers to hard resins. Polymerisamay be spontaneous, or it may be brought about by ical reagents—acids or alkalis—by heat, or sunlight. 0S it was simultaneously discovered by C. Harries and Matthews that sodium is an excellent agent for the nerisation of isoprene. The action is practically titative, and is not affected by the presence of imies. Moreover, it takes place in the cold, or on ng very moderately. Harries showed that a superior y rubber could be obtained by the polymerisation of iene. Research showed that the isoamyl alcohol ned from commercial fusel oil was the most suitable ial to work upon. By means of dry hydrochloric was converted into the chloride, and then chlorinated e the dichloride, from which the hydrochloric acid eliminated by passing over hot soda-lime. The ne was then sealed up with 3 per cent. thin sodium and heated for several days to 60°. The dark product thus obtained was treated with acetone cipitate the rubber.

To obtain fusel oil, Fernbach has worked out a new process of fermentation, starting with starch. Holt has recently made some valuable discoveries relating to the manufacture of isoprene from the fraction of petroleum of lowest boiling-point, and the preparation of butadiene from benzene or phenol, tetrahydrobenzene being formed as intermediate product. He has also observed that isoprene when treated with sodium in an atmosphere of carbon dioxide gives quite different products from those obtained by the same action in air. No perceptible change occurs at first, but finally a black voluminous mass is obtained, which gives pure white caoutchouc with water or alcohol. Recent work shows that all synthetic caoutchoucs differ chemically from natural caoutchouc. Physically the vulcanised products from synthetic (isoprene) caoutchouc are equal in quality only to products from medium grade natural rubbers.

Another series of remarkable syntheses is due to Fischer and Freudenberg, who, starting from gallic acid, have succeeded in obtaining lichen constituents and tannins, for which the general name "depside" has been suggested.

The process recently patented by Dr. F. Bergius for the preparation of hydrogen, and his investigations of the preparation of coal from cellulose at high temperatures and pressures, are of deep interest. At high temperatures water acts as a fairly strong acid or base, provided it is kept liquid. In presence of a metal such as iron hydrogen is evolved. The gas is obtained in a pure state and the speed of the reaction is very high. The cost of production is about ½d. per cubic metre at atmospheric pressure, and this would be reduced in large plants; it is considerably less than that of the cheapest method now known.

Water kept liquid by high pressures acts as an excellent thermostat in consequence of its high specific heat; this fact can be applied in the preparation of coal by the decomposition of cellulose. The product has all the chemical properties of natural coal, though physically it differs from it. If, however, the temperature and pressure during formation is greatly increased a substance is obtained which closely resembles anthracite. The specific gravity increases with the duration of compression and the temperature employed.

The use of hydrogen in the hardening of fats has recently found favour. The natural supply of hard fats is absorbed in the manufacture of margarine and other foodstuffs—hence for soap-making and other similar purposes artificially hardened fats are employed. Whale oil gives a good fat for soap-making when hardened in presence of reduced nickel; the product seems likely to be useful for lubricating and other purposes.

I may perhaps be allowed to allude to such parts of my own work as may be of interest to Industrial Chemists. Such are the investigation of the spectrum of silicon in a very pure state, and also the preparation of eye-preserving glass for spectacles. The main object of this last research is to prepare a glass which would cut off those heat rays from molten glass which are injurious to the eyes of workmen, without obscuring too much light, or materially affecting the colours of objects seen through the glasses. The research was afterwards extended to the examination of the screening properties of different glasses for ultra-violet and luminous rays, and many specimens of glasses containing known quantities of pure metallic oxides and earths were prepared in my own laboratory. I succeeded in obtaining a glass which cut off 98% of the heat rays, while others, which I have called "Anti-glare Glasses," cut off practically all the ultra-violet and a considerable proportion of the heat rays. I am now investigating the question of the choice of a glass which will reduce to a minimum the fading and alteration of the colours in water-colour paintings on exposure to sunlight and diffused daylight. This series of experiments is not yet concluded.

In spite of the advances which I have just briefly brought to your notice, and notwithstanding the fact that the active investigation of scientific and industrial problems is going on at a rapid rate, the World is greatly in need of able Researchers, perhaps more so now than at any previous time in its history. We may be certain that discoveries of vast importance are waiting their Newtons. Secrets of nature are lying hidden ready to disclose themselves to the "immortal mind." But is not the attitude of the public towards investigators lacking in understanding and imagination, and do not the authorities treat Scientific exploration in a niggardly spirit ? Scientific men have to deplore the fact that there appears to be a lack of men gifted with the genius for Research and for grappling with the Riddles of the Earth. Scientific research has been and is being starved. It is high time measures should be taken to remedy this state of affairs, which otherwise can only end disastrously for the nation. I do not wish to come before you as an alarmist, but rather as one who can diagnose the disease and suggest the remedy. I know you will be in hearty and enthusiastic agreement with me when I say that the allotment of public monies to the furtherance of scientific work, the tangible recognition of the services of scientific men, the provision of opportunities for all kinds of investigations of scientific problems without reference to their immediate commercial value—these are the benefits we look for at the hands of Government and of the Nation. And what are our responsibilities and duties in regard to research ? I think our chief care should be to see that we encourage and cultivate the right type of man for research work. We should make more definite efforts to select suitable men from among our students and to train them to the highest point of efficiency, after having made up our minds what are the special qualities we need. I think we can learn a great deal from the training of our Army Scouts. Our researchers are actually Scouts, penetrating strange and unknown countries, and the keys to success are the same as for all scouts. The principal qualifications are confidence, keenness, intrepidity, inspiration. The knowledge that you are well equipped for your work, the belief that your training has been thorough, and that you have made the best possible use of it, should develop in you the self-reliance and boldness indispensable in a scientific scout ; other valuable qualities, quickness of eye and mind, and the power of reasoning and expression, can undoubtedly be developed and perfected. And what can be promised as the reward of scientific work ?—" Not the reward, the work makes man sublime." Perhaps after all only the Fight, the Struggle, the Search—but Research, like Virtue—

> " Desires no isles of the blest, no quiet seats of the just,
> To rest in a golden grove, or to bask in a summer sky :
> Give her the wages of going on, and not to die."

Dr. MESSEL, having read the address said : You will agree that it is very remarkable that a man, the greater part of whose life work has been devoted to scientific research, should take an interest in technology such as is shown in his address, which I have just had the pleasure of reading to you. He does not, however, do himself justice. He refers here to the famous Haber process for the synthetic production of ammonia, and to the Norwegian process for the production of nitric acid and nitrates in various forms, but not a word does he say as to whom all this work is in the first instance due. It is, I contend, due to no one else than our Past-President, now the President of the Royal Society, Sir William Crookes. He says at the end of his address here : " I do not wish to be an alarmist." In his address on the great food problem before the British Association in 1898 he undoubtedly seemed to be an alarmist lest our food supply could not keep pace with our requirements. He pointed out that ever larger quantities of manurial material would be required if food supplies for future generations were to be sufficient to meet the enormous increase of population and its requirements. But though it may be right that he was an alarmist, yet he has rendered a great service by calling attention to the facts. Not sufficient stress, however, is laid on the fact that, as a true physician, he likewise prescribed the remedy. In his address of 1898 he asked if it was not possible to solve this momentous problem, and he proceeded to describe the fixation of nitrogen as vital to the progress of civilised humanity. Not only in general terms did he refer to it, but he pointed out that as far back as 1892 he had exhibited before the Royal Society an experiment on " The Flame of Burning Nitrogen." This method has since been made use of by Lord Rayleigh for the purpose of eliminating nitrogen from the air, with the object of producing argon. The data thus obtained Crookes made use of in calculating the cost of nitrate soda, and he proceeded to show that electricity produce by means of coal and steam engines would be too costl for industrial purposes, but that at Niagara, where wate power was utilised, electricity was sold at one-seventeent of a penny per Board of Trade unit, and at this rate nitrat of soda would not cost more than £5 per ton ; the lim of cost, however, had not yet been reached. He al pointed out that Niagara alone was capable of producin all the energy required to supply the world with nitr genous fertilisers, without materially reducing its might flow. The address in question has thus called attentic to the necessity of producing and fixing nitrogen in son way or another for the purpose of increasing crops. S William likewise shows how absolutely practicable would be to combine atmospheric nitrogen, whi costs nothing and which is at our hands in su quantities that it can never be a question of our having starve, if only we make use of it. True there have co after him other inventors, one greater perhaps than t other, devoting themselves to nitric acid and ammo problems, and I do not for one moment wish to ta away the credit from these great men who have bu up these important new industries. On the contra But if, at an earlier stage of this meeting, in answer some remarks of the Mayor, I endorsed the words of t King, " Wake up, England," I am equally anxi to give credit where credit is due, and to point that these vast problems were really first of suggested here in our country, and that the impu to achieve these great results was primarily to the foresight of an Englishman, Sir William Crook Then again, his reference to the work he has done w regard to the discovery of a glass that enables peo to work at furnaces without suffering injury to eyesig is of the greatest importance. He also refers here t paper on the production of hydrogen for use in connect with the hardening of fats and the production of ammo But one of Crookes' very early investigations and coveries was that of thallium in 1862, and it is notewor that now, after more than 50 years, this work has fo practical application in a recently patented pro involving the use of thallium chloride in produ hydrogen. I could not refrain from making s comments on the work and address of Sir William Croo and I ask you now to accord a hearty vote of thank him.

Prof. G. G. HENDERSON, seconding, referred to the that Dr. Messel had omitted to read Sir William Croo reference to himself in the early part of his address. Ha read the passage in question, Prof. Henderson remin them that three years ago, in recognition of his scien achievement and of his services to the Society, Dr. M was elected to the Presidential chair, that he had charged the duties of his office for the normal period the greatest advantage to the Society, and that also du the following year, when the chair was occupied by Bogert, Dr. Messel was acting as president during Bogert's absence from this country ; and finally, the Royal Society had risen up in its might and taken a from them their President, the Council had unanim agreed to ask Dr. Messel to fill the gap thus cre believing that in the interests of the Society would consent so to act. This was a unique re The Society was under a debt to Dr. Messel, w it would be very difficult to pay, but at least recognised their indebtedness by offering him their cordial thanks. That he would ask them to do.

The resolution having been supported by Mr. Eu CAREY, was carried unanimously.

The PRESIDENT, in acknowledging the vote, said the members having again shown their confidence in and having received him with such heartiness, he only say how very greatly he appreciated their kin towards him. The fact that he had had the hea support of everybody had made it possible for him to h successful year of office once more. If he had anything for the Society in the past he was only delighted to have done it, and he was equally rea assist the Society in the future.

PRESENTATION OF THE SOCIETY'S MEDAL.

The PRESIDENT then proceeded to make the presentation of the Society's medal, the recipient being the Right Hon. Sir Henry E. Roscoe, LL.D., F.R.S., who was unable through indisposition to be present. Dr. Messel first read a telegram from Sir Henry, sending affectionate greeting and wishing success to the meeting, and also a letter expressing his sincere regret that he found it impossible to attend to receive at the President's hands the medal with which the Society had honoured him. He felt confident that his enforced absence would not be taken by the members as indicating either want of interest on his part in the proceedings of the Society or of gratitude to them for the award of the medal. With regard to the first point, that was impossible for a man who was present at the birth of the Society, acted as its first President 33 years ago, and since then had watched its progress from year to year and rejoiced in its increasing usefulness. As regarded the second point, all he could say was that the honour was a great one, and for any service he had rendered to the Society in the past he had been more than amply repaid. Sir Henry then referred to the origin of the Society and mentioned that one of its objects was to promote a good understanding and friendly intercourse between professional and industrial chemists.

The PRESIDENT then proceeded as follows :—

"The recipients of the Society's medal form a record of eminence in pure and applied chemistry and in the furtherance of the objects of the Society, of which any association may feel justly proud. The addition of the name of the Right Hon. Sir Henry Roscoe, which has already been announced by the Council of the Society, will add further lustre to our roll of medallists, and will, I feel sure, be welcomed most heartily by every member of the Society.

"According to our Charter the recipient of the medal shall be a person who, in the opinion of the Council, has rendered conspicuous service to applied chemistry, or to the Society in furtherance of its objects.

"Sir Henry Roscoe's long record of eminent service both to chemistry and to the Society needs no words of mine to justify our selection, but I may be permitted to recall something of the work of his distinguished career, especially at a time when modern advances in science are apt to make us unduly forgetful of the past.

"Roscoe's earliest researches, which were conducted in conjunction with Bunsen nearly 60 years ago, were on the measurement of the chemical action of light, a series of investigations which laid the basis of quantitative photo-chemistry and which have played a large part in modern developments of the photographic industry. Some few years later, during the early days of his tenure of the Chair of Chemistry at Owens College, Manchester, he carried out his well-known work on the composition of he halogen acids of constant boiling point and on perchloric acid. Then followed in 1868 his classical research on vanadium. Roscoe proved that the substance previously described as vanadium by Berzelius was, according o the method adopted in its preparation, either an oxide r nitride. He was the first to isolate the element and to ssign to it its right place in the periodic classification ; in ddition he determined its atomic weight and prepared a arge number of new vanadium compounds.

"It is worthy to note that with all the improvements uggested by the vast amount of research work on atomic eights, both in America and in this country, practically o difference is found in the latest determinations of the tomic weight of vanadium. Many valuable technical ses of vanadium have followed in the wake of Roscoe's scoveries. Vanadic acid has been employed as an idising agent in the aniline colour industry, whilst the etal has received many important applications in tallurgy.

"Apart from these direct services of Roscoe's own work applied chemistry, he has contributed a large indirect are to the advance of chemical technology through the nspicuous success of the School of Chemistry he estabhed at the Owens College (now the University), Manester. During the 30 years of his professorship—from 57 to 1887—close on 2,000 students passed through the rriculum of his laboratories. Of these many occupy sitions of trust and responsibility in chemical industry and have contributed much to the advancement of applied chemistry.

"Roscoe's association with this Society commenced with its inception and his selection as its first President was an augury of its future success which has been so amply realised. He gave his active support to making the Society a national institution and secured the interest of many notable chemists in its work. Throughout the life of the Society Sir Henry's interest in its welfare has never waned and we owe much of its progress to his stimulating activity.

"I must not omit one other feature of Roscoe's many-sided labours which has reflected on our welfare, his work in technical education. With a firm belief in the efficacy of scientific training, he taught his students and his fellow citizens in Manchester to realise the value of the application of science to industry. He was a member of the first Royal Commission on Technical Education and during his subsequent Parliamentary career took every opportunity to forward the means for the technical training of chemists and to bring the best methods for the education of future captains of industry before the authorities concerned.

"The success that has marked all Roscoe's work in its exceptional breadth and thoroughness is the most lasting memento of its merit. Its recognition by the members of this Society is but one further record of appreciation to the many that have been accorded to him. It is the highest honour we can confer on one who has done much for the advancement of chemical industry and who by his wonderful personality and high character has endeared himself to us all.

"May he long be spared to us !"

Dr. MESSEL intimated that Sir Henry had asked him to receive the medal on his behalf, and he would hand it to him in due course in the name of the Society.

ELECTION OF AUDITORS.

On the motion of Mr. W. T. GENT, seconded by Mr. S. H. DAVIES, Messrs. Feasey and Co. were re-elected auditors at a fee of 20 guineas. Mr. Davies said he hoped that the suggestion of seeing whether some papers of scientific interest could not be arranged for at the annual meetings would be considered. They did not want to belittle the social side, but as they generally met sectionally all the year through it was desirable that something more should be added to the Annual Meeting.

The PRESIDENT intimated that the matter had been favourably discussed by the Council, and the resolution was carried unanimously.

ELECTION OF COUNCIL AND OFFICERS.

The PRESIDENT announced that 128 ballot papers had been examined of which 4 were spoilt. The nominations for President, Vice-Presidents, and officers were confirmed, and the following had been elected ordinary members of the council : Mr. J. H. Coste, Professor F. R. Ruttan, Mr. A. Gordon Salamon, and Mr. J. T. Wood. A list of the new Council will be found on page 717.

NEXT YEAR'S MEETING.

Mr. J. HÜBNER said the Council had kindly accepted an invitation to hold the next annual meeting of the Society in Manchester, and it was his pleasant duty to extend to the Society a most hearty welcome. In 1915 they would be in an exceptionally fortunate position as the British Association were to meet in Manchester and extensive preparations for it would be made. Many of these he had no doubt their Society would also be able to enjoy.

Mr. HOSEASON supported the invitation, which was unanimously approved, and the PRESIDENT, on behalf of the Society, tendered to Manchester a hearty vote of thanks.

THANKS TO UNIVERSITY COLLEGE.

The PRESIDENT said that they were grateful to the authorities of University College for lending them that splendid room. The interests of the Society were identical with those of Colleges like the one in which they met. It was very important that colleges should keep in touch with applied science, and that the Society should keep in touch with the colleges.

Sir JOHN TURNEY said he had been asked to second the vote, but it seemed rather strange that he should be doing so, because indirectly he was associated with University College as a member of the City Council, which he had been for a few years. However, he would like to say on behalf of the people who controlled the work in this College that they were always willing to do all they possibly could to forward that which was for the benefit of the people in regard to things scientific or practical.

The meeting then closed.

VISIT TO SOUTHWELL CATHEDRAL.

After luncheon at the Victoria Station Hotel, by invitation of the Nottingham Section, members and ladies proceeded by motor to Southwell where they visited the Cathedral, Chapter House, and ruins of the Palace of the Archbishops of York.

GARDEN PARTY AT BRACKENHURST HALL.

On leaving Southwell, the party drove back a short distance to Brackenhurst Hall where they were entertained at a garden party by Mr. and Mrs. W. N. Hicking. Tea was served in the park, and was followed by a pastoral play entitled the "Spirit of the Future," rendered by Miss M. Pratt and Messrs. Carey and Creighton. In the intervals, music was rendered by an excellent band. Mrs. Hicking escorted parties round her fine rose gardens, and identified many rare trees and shrubs.

RECEPTION AT THE CASTLE.

The Mayor and Mayoress of Nottingham received the guests in the Art Gallery, Mr. Charles Foulds' orchestral band played in the Long Gallery, and refreshments were served in the Textile Gallery.

SECOND DAY.

VISITS TO WORKS.

THE CORPORATION GAS WORKS.

The Nottingham Gas Works were founded in 1818. and have been gradually extended to their present productive capacity of 10½ million cubic feet of gas per day (including 1½ million cubic feet of carburetted water gas).

The gas is produced at three different works:—

Basford.—Horizontal retorts fitted with West's compressed air charging and discharging machinery.

Eastcroft.—Horizontal retorts fitted with De Brouwer electrical stoking machinery; also inclined retorts.

Radford, where an installation of vertical retorts (continuous carbonization) has recently been put into operation. There is also one bench of hand-worked retorts still standing at Radford.

The district served by the Nottingham Gas Department covers an area of 130 square miles, the total length of mains being upwards of 400 miles.

The tar produced is distilled at the Giltbrook Chemical Works, where also the manufacture of sulphuric acid and artificial oxide of iron is carried on. The sulphuric acid is made principally for use in the sulphate of ammonia plant at the Basford Works, where about 2,300 tons of sulphate are manufactured annually. The oxide is used at the different gas works in the process of purification.

The following figures relate to the year ended March 31st, 1914:—

Coal carbonized	190,025 tons.
Gas oil used	131,911 gallons.
Gas made	2,332,876,000 c. ft.
Gas sold	2,251,303,000 c. ft.

NOTTINGHAM CORPORATION ELECTRICITY WORKS.

The Nottingham Corporation own two electricity works, the one in Talbot Street, the other in St. Ann's Well Road. The output of these Works last year was approximately 13½ million units. The St. Ann's Well Road Works contains 16 Lancashire boilers, 30 ft. by 8 ft., eight of which are fitted with Vicars' mechanical stokers and coal conveying plant. There are 2 Green's fuel economisers and 2 Berryman feed water heaters. This generating plant consists of eleven Willans-Siemens sets of 440 kilowatts each, and a 1200 kilowatt Willans exhaust steam turbine coupled to two Siemens continuous current generators arranged in tandem. The condensing water is artificially cooled by means of a Balcke cooling tower.

TURNEY BROTHERS, LTD., TRENT BRIDGE LEATHER WORKS.

These works were established in 1862 by the brothers Edward and John Turney, and stood originally on an island surrounded by canals and the River Trent. A considerable part of the canal has been filled in since 1898, and buildings have been erected upon the site. The area at present is 2½ acres, and the number of workpeople employed is from five to six hundred.

Near the entrance to the central yard are the main boilers, Lancashire type, 3 in number, 28 ft. by 8 ft. supplying steam to 15 engines, and also very largely for boiling and heating purposes. Two smaller boilers in other parts of the works supply steam to special departments. There is a large number of electric motors, many of which are attached to separate machines.

The bulk of the skins worked are sheep, but goat and calf are also used. The sheep skins are received from the fellmonger after the latter has removed the wool. The skins are first inspected and classed in the central yard, and then pass to the liming process. As this occupies from 2—3 weeks, a capacity of over 100,000 skins is necessary in the "pit sheds." After liming the skins are taken by the "cobbers," who remove any wool or hair still adhering, and also cut off the heads. The pelts are then handed over to the "fleshers" who remove the flesh by means of knives over wooden beams. The flesh is afterwards pressed in a hydraulic press to recover the grease contained in it. The "pieces" are sent to the glue works for making into glue and gelatin. After fleshing, the skins pass on to the "splitting" shop, where they are carefully sorted into various substances and qualities, and then split by machine. The wool side is then known as a "grain," the flesh side as a "lining." From the splitting shop the two sides of the skin take different channels. The grains are washed to remove the lime, bated or pierced, scudded in special machines invented by Sir John Turney, then "drenched," and are ready for the tanning process proper. For this, ground sumac leaves imported from Sicily are used, and the tanning conducted in paddles, the time taken being about 24 hours The tanned skins are dried in the weather, and are then known as "skivers." The drying rooms are very extensive and capable of holding over 50,000 skins. They have been recently enlarged. Large quantities of skins are tanned without splitting, and are known as "basils," part being tanned with larch bark and part with extracts.

Another tannery is devoted to chrome tanning of sheep and lamb skins for motor clothing and for shoe linings and other purposes. Calf skins are also tanned for hat leathers and for shoe work, bookbinding, etc. A special department is devoted to the manufacture of hat leathers. Sheep skins contain much grease, and one of the features of the works is the plant for extracting this by volatile solvents and afterwards recovering both the grease and the solvent. Grease is also removed from some skins by hydraulic pressure. The flesh side of the skin is made into chamois leather, and goes through the following processes: (1) Frizing; by which the skin is cut dow or shaved by skilled workmen to the proper thickness (2) liming, (3) washing, (4) pressing in hydraulic presse to remove water, (5) milling with fish oil, (6) stoving (7) heating off, (8) pressing to remove the oil, which i completed by (9) scouring. The oil pressed from th leather is known as sod oil, and is used for currying heav leather. The finer sorts of chamois go for gloves, th poorer quality for wash leathers.

THE LACE WORKS OF MESSRS. THOMAS BIRKIN & CO.

The oldest part of this factory dates back about 8 years, and contains a machine built by Mr. R. Birkin f the 1851 Exhibition. About eight hundred people a employed in the factory, and the work comprises all t different processes for the production of lace, from ya in the hank to the finished product ready for use. The operations carried out include designing, drafting, slip winding, brass bobbin winding, warping, threading, actual lace making and also all the finishing processes such as mending, dyeing, dressing, drawing, clipping and scolloping.

Various processes in connection with the Lace Curtain branch of the firm's business are also carried out in the Nottingham Works. Among these are the production of the designs and their preparation for the jacquard process, and the mending, finishing, and packing of the goods.

The consumption of cotton yarn involved, both American and Egyptian, amounts to from 7 to 10 tons a week.

The Works of the Raleigh Cycle Co.

The Raleigh Cycle Company was founded twenty-five years ago, and in 1896 the present works in Faraday Road, Lenton, were opened. The frontage is 400 ft., the depth 552 ft., and the building covers an area of over 6 acres. Over 1,600 workpeople are employed and the annual output amounts to 60,000 bicycles, in addition to 150,000 Sturmey-Archer gears, and a large number of motor cycle gears, coaster hubs, etc.

Among the chief characteristics of the Works is the ery complete equipment of power processes. Excellent esults are achieved in the shaping of handle bars, crank rackets, frame loops and other portions of the bicycle rom sheets of high-grade cold-rolled steel.

In the liquid brazing plant a much more certain junction s effected by dipping the frames into molten brass in rucibles, than by the ordinary method of hand brazing t an open hearth with fire and blow pipe.

"Coslettising," a process for forming a rust-resisting eposit upon tubing and other parts before enamelling, as seen in operation; and in the wheel building departnents some clever devices for spoke making, cutting, eading, bending and threading were shown.

The Company makes its own gas for driving, heating nd manufacturing purposes, and the power required for riving the machinery is obtained from eighteen gas ngines, with an aggregate brake horse power of 972.

The most recent addition is a tube making and welding lant. Long strips of sheet steel are drawn through dies nto tubular form, their edges welded by the oxygencetylene process, and the tubes passed through finishing ies, the result showing an improvement upon ordinary ubing both in strength and appearance.

Boots Cash Chemists.

This business consists of five companies, all of which raw their supplies from Boots Pure Drug Co., Ltd., of ottingham. Their combined capital is approximately 2,500,000. The companies employ over 9000 people and ay over £10,000 per week in wages. They control 560 ops and employ about 800 qualified chemists.

The premises in Nottingham occupied by the companies mprise extensive offices and at least ten factories. The fices of all the companies, with a floor space of 81,583 uare feet and a staff of 560 persons, are collected under e roof at Station Street, Nottingham.

After inspecting the various office departments, the sitors were shown the girls' gymnasium, the patent edicine stock room, the printing works, and finally the w pharmaceutical laboratory.

E Locomotive Works of the Midland Railway at Derby.

On these works devolves the duty of building the comotives of the Midland Railway, and maintaining in nning condition the 3000 locomotives owned by the mpany. The works date back to the days before 1844, en the North Midland, the Midland Counties and the rmingham and Derby railways were separate organisaons. The area covered by buildings alone is about acres, with ground amounting to about 80 acres, and devoted solely to the locomotive department, the rriage and wagon works having been moved to a new e in 1873. The number of workmen employed in the omotive works amounts to 4264, that of foremen, rks, draughtsmen, etc. to 383. Some of the more portant departments visited were the boiler shop, the eel and tyre shop, the press shop, the foundry with a weekly capacity of about 420 tons, the machine shops containing about 570 machines, the erecting shop which will hold 72 engines, and the paint shop.

Most of the machines are electrically driven, the power being generated in the company's own station by means of two 1250 K.W. Parsons' turbogenerators producing three-phase alternating current of 50 cycles and 440 volts. This station also supplies the Carriage and Wagon Works.

The new chemical laboratory has been built on the site of the old electric light station, and is fitted with the most recent appliances for chemical, physico-chemical, metallurgical and metallographic analysis.

The Works of the Royal Crown Derby Porcelain Co.

The following is an account of the history of Derby China, abstracted by kind permission from the Porcelain Company's book: "The Story of Derby China."

Porcelain was first produced in Derby very soon after its introduction into Europe. Although it was not until the early part of the 18th century that John Böttger, the pioneer of the ceramic art, made his important discovery, a China Factory was established at Derby, on the Nottingham Road, by William Duesbury in 1750 and the Derby ware soon attained national fame. It furnished the tables of the King, and was sought after by the nobles. Duesbury acquired the right to use the Royal Crown to distinguish his wares, and his factory became the most celebrated of its kind in the United Kingdom. In 1769, Duesbury acquired the famous factory at Chelsea, and it and the Bow Works which were shortly afterwards established were in 1776 amalgamated with the Derby factory.

On the death of Duesbury in 1786 he was succeeded by his son William, and from him the works passed, at short intervals, into the hands of Messrs. Kean, Bloor, and Clark, until, in 1848, they were closed down. The production of china in Derby was, however, not allowed to die out. Mr. Sampson Hancock, assisted by other hands from the Bloor factory, carried on a small works, which produced articles of the old type and character. In 1877 a Company, styled the Derby Crown Porcelain Co., Ltd., was formed to revive the industry, and works were established on the Osmaston Road. Considerable success attended the venture, and in the year 1890, on the representation of the 7th Duke of Devonshire, Her Majesty, Queen Victoria was graciously pleased to command that the Company should in future be styled The Royal Crown Derby Porcelain Company, Limited.

The Company's craftsmen have been and are, in the very front rank of their profession. Among them may be named Desiré Leroy, who made a speciality of old-time Sèvres flower, bird, and trophy painting, and was also strikingly successful with white enamels. Another artist whose work is well known is A. Gregory, who has made a special study of flowers.

The Works of Bemrose and Sons, Limited.

Fine Art, General, Railway, Calendar and Collotype Printers, Lithographers, Manufacturing Stationers, Bookbinders, etc.

The firm was established in 1825, by the late Mr. William Bemrose, and converted into a Limited Company on December 21st, 1891. It has branches in London and Leeds. Messrs. Bemrose and Sons, Limited, are the Printers to the Midland Railway, and their works are situated close to the Company's Offices. The premises cover an area of 78,768 square feet, excluding outbuildings and open yards. The number of employees is 1100.

The chief speciality of the firm is fine art and colour printing, and they possess for the production of this class of work facilities which embody the latest types of modern machinery.

Some of the departments shown to visitors were the Composing Rooms (including the Linotype Gallery and the Monotype installation) the Bindery, the Folding Department, the Rotary Printing Machine, the Engine Room, the Machine Ruling Department, and the Envelope and Die Stamping Room.

The Motor-Car Works of Messrs. Rolls-Royce, Ltd.

The first car of the Rolls-Royce make, a two-cylinder vehicle of 10 h.p., was produced in 1904, and was in the same year, awarded a Special Medal and Diploma by the Commissioners of the Paris Salon. At the present day the only type of chassis manufactured is a 40-50 h.p. six-cylinder model.

The various operations are carried out in more than a dozen buildings. Of the more important departments, mention may be made of the shop containing the automatic and semi-automatic machines, the grinding shop, the coppersmiths' shop, the smiths' and hardening shop, the pattern shop and foundry, the axle-testing and gear-box testing shops, the large main shop in which beside a number of machine and fitting bays is housed the erecting bay, and lastly the testing department for the finished car.

The automatic machines produce parts to gauges having predetermined limits of error; most of these parts are handed to other departments for finishing.

Wherever extreme accuracy is required on diameters or bores the parts are handed over to the grinding department, where there are machines by means of which crank shafts are ground on the pins and journals, to produce a perfectly round and accurate diameter, also cylinder-grinding machines, piston ring grinders, ball race grinders, and various surface grinders.

In the smiths' and hardening shop were seen the hardening and carburising furnaces, in which practically all the steel parts used in the car are heat-treated at some point in the course of their manufacture.

In the foundry are two oil fired tilting furnaces, one of them of the latest pattern.

The completed cars are first subjected to a preliminary examination, and are then passed over to the testing department, in which after various other tests they are placed on one of the dynamometers. They may thus be submitted to a far more rigorous test than is possible on the road, *e.g.*, they may be run for long periods at full load or they may be run under full load at various speeds. Before despatch the chassis undergoes several road tests during which the various adjustments are completed.

A special testing track is owned by the works and an experimental shop is also provided in which any new designs are developed and thoroughly tested preparatory to their adoption as standard

Garden Party at Gedling House.

In the afternoon, members and ladies went by special train to Gedling, near Carlton, and walked to Gedling House where they were received by Sir John Turney, Chairman of the Section, and Miss Turney. Gedling Park differs from Brackenhurst in that it depends for its beauty on its fine timber, in which Sir John Turney takes the greatest interest. The trees were of great service to the garden party as the afternoon turned out wet, and refreshments were thus served under natural shelter. A photograph of the President, the President Elect, the Mayor, Sir John Turney, and other Members of Council was secured by Mr. J. W. Russell, of Hounds Gate, Nottingham.

THE ANNUAL DINNER.

The Annual Dinner took place on Thursday evening, July 16th, in the Council Chamber of the Exchange Hall. The President (Dr. Messel) presided, and was supported by the Mayor and Mayoress, Professor G. G. Henderson, Sir John Turney, and many others.

The toasts of "The King," "The Queen, Queen Alexandra, the Prince of Wales and other Members of the Royal Family," and "The President of the United States of America," were submitted by the President and fittingly honoured.

Professor G. G. Henderson proposed "The Society of Chemical Industry." He said that before he addressed himself very briefly to the toast he wished to thank the President and the members of the Society for the very great honour they had conferred upon him by electing him as their President. He knew only too well that it was no easy task to endeavour to tread worthily in the footsteps of the great men who had occupied the chair of that Society, but he could at least promise them that he would do his best, and no man could do more. He thought every member of the Society ought to consider it a privilege to propose this toast, because every member must feel, as he did, a very great pride in the past history of the Society and very great confidence in its future. Since it was born, now more than 30 years ago, the Society had never looked back: it had gone on from strength to strength until, numerically at least, it could claim a place amongst the greatest technical Societies. And if they tried to find a reason for this great, this amazing development, one, of course, was that there was need for the Society; but another, he thought possibly of equal importance, was that the foundations of the Society were laid with wisdom and remarkable foresight by those who presided at its inauguration. This Society was a composite organism. It was built up, as they knew, of a number of different Sections in this country, and also in Canada, Australia, and the United States of America. Each of these Sections was practically a society within a society, but all were linked together directly by means of the upper house—if he might call it so, the Council; and the strength of the Society arose not so much from the fact that they had a number of independent, active Sections, but that these Sections were united together. In that respect, as was true of all other societies, it was union that was strength. At the same time, a Society such as ours, however strong it might be, could not stand still: it must advance, or it must of necessity fall behind; and, as the report had informed them, methods of promoting further development and strengthening it still more were engaging the serious attention of the Council under the fostering care of Dr. Messel. But let them remember that however good a Council the Society might have, however much it might record, and however hard it might work, it could not advance unless members also fell into line with the Council, and thus he appealed to every individual member, and more particularly to the younger members, to take an active part in the work of the Society as a whole and of the Sections to which they belonged, and especially to contribute to the proceedings of the Section. Even the sun had its spots, and this Society was not quite perfect, and one of the imperfections—a marked imperfection—to his mind was to be found in this fact, that they had a huge membership, a membership of very high qualit indeed, and yet the number of original contribution received from that huge membership was most distinctl not what they were entitled to expect. There were, o course, obvious difficulties in the way, but he though that if the members acquired the habit—if he might cal it so—of publication to a larger extent, the Journa would be very much stronger than it was and thes comparative difficulties would disappear. He desire to remind them that the Society's year which they ha just brought to a conclusion had been a notable one i various ways. They had only just heard of the resignatio of the first and only Editor the Society had ever had It was not necessary for him to say anything, he thought beyond reminding them that there was a stately ro of witnesses to the capacity, faithfulness, and loyalty t their Editor in the great series of volumes of the Society' Journal which had been issued under his direction. H would say one word only—that no Society had ever a mor loyal officer than they had had in their Editor. In anoth way this had also been a very notable year: they had ha two Presidents. They all knew the circumstances unde which Sir William Crookes was torn from them, and the also knew how the Council felt that one man—and o man only—could fill the breach created in their rank and how that man—of course, as they expected—ro to the occasion. Dr. Messel was almost a unique Presiden He did not know of any other man who had acted President for three years, and he should feel it a impertinence to endeavour to say more than a single word i commendation of his services to the Society. He woul however, say one word. That was that he had made very difficult for any man to succeed him. But he wou like to remind them that it was no recent development Dr. Messel's part to be an active worker in th Society. Since its foundation he had been intimate associated with it. If they would turn to the fir volume of the Journal they would find that the fir paper in that volume was contributed by Dr. Messel, a ever since that date he had taken an active, strenuo and invaluable part in promoting the development a the great prosperity of the Society, and they rejoiced that they could still depend upon the benefit of his wisdom and experience upon the Council. He asked them to drink with all heartiness to the general prosperity of the Society and especially to drink to the health of Dr. Messel.

The **President**, in responding, referred to the election of Sir William Crookes as President of the Royal Society which prevented his continuing to hold the Presidency of the Society of Chemical Industry. The Royal Society knew a good thing when they saw it, and they had come to the Society of Chemical Industry to find it. The Council had come to the decision, with reference to their annual meeting, that some time should be devoted to the consideration of special subjects, but as that would not come into operation until next year they could enjoy themselves this year. He had become so accustomed to the chair that he should be quite sorry when his year of office expired. But to be quite serious, he wished to return them his very sincere and grateful thanks for the support he had received during the years he had had the honour to fill the chair.

Mr. W. F. **Reid**, past President, submitted the toast of "The City and Institutions of Nottingham." He said he felt that he ought to say "My Lord Mayor," because a city of 270,000 inhabitants and which had had a Mayor for 600 years certainly deserved one. At any rate no worthier holder of the position of Mayor was needed than the present occupant of the office. He had been present on the historic occasion when the King had advised England to "wake up," but he felt sure that Nottingham was one of the last places in the world where that admonition was required. They could not fail to be impressed not only by the importance of the industries of this neighbourhood themselves, but by the finished way in which the work was conducted—the organisation of the business, the machinery used, etc. In every way Nottingham was absolutely up to date in manufacturing processes. Nottingham lace was worthy of being used and treasured not because of the way it was made, but because it was beautiful. The lace industry was a very important one, but there might be dangers ahead from lace made without the intervention of spinning or weaving at all—by a simple chemical process. A thick solution made by dissolving old linen was passed over an ingrained, rotating cylinder and the product was peeled off. It had, however, one defect: it was not quite so durable when moist. At the same time, as artificial silk had not diminished the consumption of natural silk, but rather increased it, so an article of this kind might also increase the sale of the genuine article. This artificial lace was used a good deal in Paris, he believed in millinery. There was also an intimate connection between the hosiery trade and chemical industry. Again, some of the leather made in Nottingham was the best that was made in this country: what he had seen in the factories of Nottingham convinced him that the care devoted to the production of leather and in the selection of the material used was a guarantee that leather made in Nottingham was beautiful as well as lasting. Having mentioned also the tobacco industry, Mr. Reid proceeded to say that he did not think there was any city outside Nottingham where there were so many small industries, which meant, moreover, that there was an endeavour on the part of individuals. All these industries employed a large number of people. The preponderance of women, he understood, was a feature of Nottingham: it showed that there was a suitable class of labour for them, and that they felt that they were earning their living in a congenial way.

The **Mayor** acknowledged the toast, remarking that the position of the leather industry was largely due to Sir John Turney, of whose works they were very proud. They were also proud of his connection with the public life of the city, no man having filled public offices with greater ability and distinction than he. The business of Boots was established by Sir Jesse Boot not more than 25 or 30 years ago, and it was now a vast concern. The city highly appreciated the work that both Sir Jesse and Lady Boot had done, the benefit of which was felt all over the country.

Professor **Kipping** also acknowledged the toast, referring to the connection of University College with the local Section of the Society of Chemical Industry. The College welcomed the Section and provided it with what accommodation it had at its disposal. A great effort was being made to obtain a full charter for the College and transform it into a University for the City of Nottingham and the East Midlands, and he hoped that when the Society of Chemical Industry met in Nottingham again the University would have some years of successful progress behind it. He would like to mention the name of Dr. Sand, their honorary local secretary, in connection with University College and the local Section, to whose efforts so much of the success of the present meeting was due.

Mr. **Thomas Tyrer** proposed the toast of "The Sections of the Society." He was convinced that the Sections had a unique opportunity of justifying their existence. There was no reason why the Sections should not become greater centres of activity than they had ever been. Excellent work had been done, and members could show their greater appreciation of the Journal by contributing papers. There was no Section which contributed more useful technological papers, crisp and to the point, than Nottingham. Mr. Tyrer referred to the services of Mr. Archbutt, Mr. Trotman, Mr. Pentecost, Mr. White, and Dr. Sand.

Sir **John Turney** responded to the toast.

Dr. **Russell W. Moore** proposed the toast of "Our Guests," which was suitably acknowledged by Mr. G. Thornton-Simpson.

Some of the members availed themselves of the privilege of honorary membership conferred on them by the Notts Golf Club at Hollinwell. The Constitutional and Reform Clubs also opened their houses to members.

THIRD DAY.

Excursion to the Dukeries.

Members and ladies left early by motor. The route was past Rufford Park, through Edwinstowe to Welbeck Abbey, where, by kind permission of the Duke of Portland, the stables, gardens, underground rooms, chapel and library were visited. Luncheon was taken in the riding school, at which the President acknowledged the obligations of the Society to the Duke for his courtesy, extended to the Society not for the first time. The President also took the opportunity to offer a special welcome to Mr. John Hargreaves, one of the founders of the Society, who was present.

In the afternoon Clumber Church was visited by permission of the Duke of Newcastle, and the homeward way was through the Lime Tree Avenue and Normanton, past Thoresby House to Ollerton, where tea was taken.

Reception at "Plaisaunce."

Sir Jesse and Lady Boot received the members and ladies at "Plaisaunce," their summer house at West Bridgford, and offered them a charming entertainment.

London Section.

Meeting held at Burlington House, on Monday, June 8th, 1914.

PROF. W. R. HODGKINSON IN THE CHAIR.

BLEACHING EFFICIENCY CONSIDERED IN CONNECTION WITH SUGGESTED STANDARD FOR TESTING BLEACHING QUALITIES OF CHEMICAL WOOD PULP.

BY CLAYTON BEADLE AND HENRY P. STEVENS, M.A., PH.D.

We regret very much that we were not able to be present at the reading of Messrs. Baker and Jennison's paper, but our experience so far as it goes appears to fall in with several of the observations and conclusions arrived at by these authors.

We have had a good deal of experience in bleaching at different temperatures in paper mills, and one of us devised a circulating bleaching system for rags which was in use for many years, whereby the liquor in course of circulation was continuously drawn from the bottom and sprinkled upon the top of the material. The liquor was maintained at a constant temperature by means of live steam. By studying the temperature and observing the conditions of the bleached material, we came to the conclusion that the result was as good in point of strength of fibre, yield, etc., at 100° F. as at any lower temperature, but that immediately we raised it to say 110° F. or over, we noticed weakening and deterioration of the material as well as increased consumption of chlorine. We therefore maintained the circulating liquor at 100° F. and the bleaching was done in about one-eighth the time of that required at an ordinary atmospheric temperature. This seems to confirm Messrs. Baker and Jennison's statements for wood pulp.

Then, as regards the use of spent liquors, if liquor is drawn from a material which is in course of bleaching and periodically titrated for chlorine strength, it will be found that the chlorine strength diminishes after the liquor is out of contact with the material to be bleached, and diminishes fairly rapidly.

Another factor in bleaching is the question of agitation, which is a very important one. It is a common practice in some mills to add bleach during the process of beating, especially in rag mills. One of us has made determinations of the rate of exhaustion of bleach during the process of beating and compared the chlorine consumption with that of material bleached, say in the form of half stuff, but without undergoing the beating operation, and discovered that for the same amount of bleaching effect, the material which is undergoing beating consumes only about 40% of the amount of chlorine as compared with that in the form of half stuff which is not being circulated or beaten.* With electrolytic bleaching for linen half stuff a saving of 30% was effected, and for cotton half stuff, 47%, by circulating in comparison with non-circulating of liquor. No doubt the circulation and the rapid agitation in contact with air, and possibly with the assistance of carbonic acid of the air, enormously accelerates the action, as well as making it more economical. Although concentration is a very important factor in the economy of bleaching, agitation is also important, particularly if the beating operation is proceeding at the same time. We have found that, when comparing bleaching efficiencies of different hypochlorites solutions such as by making a comparison between (a) bleaching powder solution in its normal condition, (b) the same on the addition of sufficient acid to combine with the base, (c) sodium hypochlorite, and (d) calcium hypochlorite produced by bubbling chlorine into milk of lime, as well as (e) hypochlorites in the presence of salt, a certain relationship of efficiencies is obtained with any one particular material at a given concentration, temperature, etc., but if several materials are compared with one another, these various solutions behave relatively differently both in regard to efficiencies, *i.e.*, chlorine consumption and rapidity of action, so that it cannot be said that one particular form of hypochlorite is more efficient than another except in relationship to one given material to be bleached, and under given conditions. For instance, we have compared chemical wood pulps with different forms of cotton half stuff and we have found these different hypochlorite solutions to behave relatively very differently.

Quite a number of papers have recently been published on the subject of relative bleaching efficiencies of the hypochlorites. The conclusions arrived at in most cases are in our opinion most erroneous. First of all there has only been one kind of raw material experimented upon, such as boiled linen, and another material might have led to quite a different order of so-called efficiencies. We have an instance in the above-cited comparison of cotton and linen half stuff and wood pulp compared with cotton half stuff. Secondly, the relative efficiencies have been expressed as chlorine consumption per unit weight of raw material on the assumption that the same bleaching effect is always accompanied by the same chlorine consumption, the higher the figure in unit time, the greater the so-called efficiency. As a fact, the reverse is the case. The relative efficiencies of all hypochlorite solutions should be judged by the amount of chlorine consumed per unit of bleaching effect, and the smaller the chlorine consumption the greater the efficiency. Thus the Hermite solution was found to be much more effective than the ordinary bleaching powder solution because the chlorine consumption per unit of bleaching effect was so much less than with ordinary bleaching powder. This, from the fact that a large amount of unelectrolysed salt is present, may be accounted for by the influence of the undecomposed salt and not by any special qualities of the electrolysed hypochlorite, as it is now found that salt, when added in different quantities to solutions of hypochlorites, has a marked effect upon their efficiency.

In many cases, certainly, the addition of the spent liquor is a doubtful economy, as Messrs. Baker and Jennison clearly show in their paper, but we know cases in practice where the bleaching liquor which would otherwise have to go to waste is usefully expended by using it as a wash water in the breaker, the unbleached material in a very few moments completely exhausting the chlorine, after which, it is slightly further washed and then fresh bleach is added. In this manner the spent liquor is taken out of the sphere of action before the fresh liquor is added.

We have often found that bleaching is much more effective if followed by an acid treatment or by washing and then again bleach added. Many materials seem to come to a full stop unless the bleaching products are removed. Furthermore, the addition of acid after the hypochlorite bleaching very materially improves the colour in many cases. The "more water more bleach" maxim is fully borne out in the results obtained by the Dobson process where the material is bleached with the maximum concentration, the amount of total liquor being only enough to make the material wet, and furthermore, in the old-fashioned method of tumbler bleaching, as was employed in the early days for rags. We have recently drawn attention to the fact that, with some lignified fibres, chlorination is produced in acid solution of hypochlorites (*i.e.*, by hypochlorous acid) but in alkaline solution the ordinary bleaching effect is produced. Either one or the other effect is brought about according to whether the solution is rendered basic or acid, but the behaviour is largely controlled by the amount of boiling to which these lignified fibres have been previously subjected.

The use of carbon dioxide as an accelerator to bleaching powder was patented by Thompson in 1883, B.P. 959. One of us tested this process at the time that it was under investigation by Cross and Bevan, and subsequently suggested in a publication the use of carbonic acid gas by discharging same under the roll of a potcher or hollander in which the bleaching operation was going on. On visiting a German mill many years afterwards we saw this very operation. It is quite evident that a relatively small amount of carbon dioxide is sufficient to produce a marked acceleration which rather suggests that carbon dioxide acts catalytically. Very good commercial results are got and it is well worth while following up, but so far no relative figures are available for comparing the bleaching efficiency of such a solution with that of ordinary bleaching powder without carbon dioxide as an accelerator.

We have tested a process which involves the use of liquefied chlorine in steel cylinders. This has been in use for some years on the Continent. This bleaching process in some mills shows a considerable economy, in point of bleaching value and also in actual cost, over ordinary bleaching powder. For this purpose the chlorine is supplied in cylinders under a pressure of 5 atmospheres at 15° C. The process is conducted in the following manner :—

The half stuff is run off on an ordinary wet end machine and delivered in rolls containing from 40—50% moisture. These rolls are packed through a manhole door into a large rectangular cement-lined chamber. The chamber is then hermetically sealed. The cylinder containing chlorine is placed on a weighing machine and connected up with the chamber, and chlorine gas passed in equal in weight to 2% of the dry weight of the material under treatment. At the beginning there is considerable pressure in the chamber. After a few hours the whole of the chlorine is absorbed, there being no trace of chlorine when the workman enters for the removal of the rolls. The rolls are penetrated to the interior and uniformly bleached. There are no lime salts but of course a slight hydrochloric acidity, which is sufficient to dissolve any basic salts already present in the half stuff. The bleached stuff, which is now place in the beater, generally receives a slight further treatment with bleaching powder solution. In a case of cotton rag half stuff, which under normal circumstances requires 12% of bleaching powder, the consumption by the above treatment was 2% of chlorine + 2% bleaching powder, and with a better colour produced than can be obtained by bleaching powder alone. The point here is that, apart from a better colour, 2% of chlorine as gas replaces 10% of bleaching powder and therefore 2% of chlorine as gas is equal to 3·5% chlorine as bleaching powder; that is, the bleaching efficiency of chlorine as gas in this case is nearly double that of bleaching powder. In fact, for equal colours it is probably more than double but in point of fact it shows quite as great an increase in bleaching efficiency as an electrolysed solution of magnesium chloride + sodium chloride does over that of ordinary bleaching powder. Besides seeing it operated as a regular process in Germany we have tried it in this country. The only difficulty here is the question of transport of the compressed chlorine in cylinders, which is not an easy matter to arrange with the railways.

---

* Beadle, Chapters on Papermaking, Vol., 1 p. 57.

With iron mordanted rags, bleaching powder sets the iron in a more insoluble condition. In such cases, when bleaching powder is used, it is preferable to acidify for the removal of the iron before adding the bleaching powder solution. Otherwise the iron salts frequently refuse to dissolve by subsequent acid treatment, but in the case of chlorine, the iron is chlorinated and consequently easily removed by subsequent washing. In Germany the Badische Co. are able to supply to some mills chlorine in this form at a rate that renders the process cheaper than using bleaching powder. They generally supply the gas in cylinders for use by bubbling into caustic soda, 12·87 kilos. of chlorine being required to transfer 100 kilos. of lye of 14·5% NaOH into bleaching liquid (sodium hypochlorite).

Some years ago one of us made trials in a paper mill on a commercial scale with potassium permanganate in comparison with bleaching powder, and found that 1 lb. of bleaching oxygen as contained in permanganate did just as much bleaching as 5½ lbs. of bleaching powder oxygen when reckoned from the available chlorine equivalent of ordinary bleaching powder. The rapidity of attack in the case of permanganate is infinitely greater. Generally speaking, the rapidity of attack and bleaching efficiency seem to go together.

The foregoing examples, which might be multiplied, merely serve to show that there is a range of bleaching efficiency varying with the bleaching agents and the materials operated upon, as well as with the conditions employed.

In spite of all the work that has been done upon the subject, the economic problems involved in such operations offer one of the most promising fields for industrial research. To arrive at practical conclusions it is most important that the work should be done under mill conditions, or at least having due regard to mill conditions.

It is perfectly clear, therefore, that in the case of disputes as to the bleaching qualities of pulps, etc., a great difference of opinion might exist between the two parties, and it is a most desirable thing that a uniform and standard method should be agreed upon not only in case of dispute, but also on the question of making contracts. Messrs. Baker and Jennison have made out a very excellent case for their own standard which could easily be worked out in an ordinary laboratory, and the proposal to use standard colours in the form of porcelain is far more workable than recording the colours by means of the Lovibond Tintometer, and would appeal to the practical man. We would suggest, however, that instead of specifying that a pulp should exactly correspond with any particular one standard, it should be specified that it should fall between two of the standard colours, on account of the fact that there might sometimes be a dispute as to which of the particular standards it most closely corresponded with, but, if it falls between two, then there can be no question, and it gives a slight latitude to the manufacturer.

Discussion.

Mr. A. **Baker** thought that the treatment of rags for the production of high priced rag papers could almost be regarded as a specialised branch of paper manufacture, because in rags the fibres were spun, whereas in chemical wood pulp they were dealing with ultimate fibres. In the former case, no doubt, it was more economical from a chlorine point of view, certainly from a power point of view, to do a portion of the bleaching during the breaking and possibly during the actual beating operation. He thought, however, that it was far better to make the bleaching of chemical wood pulp a separate process.

They were inclined to think that the effect of agitation was somewhat over-estimated, and were firmly of the opinion that concentration was even more important than agitation. In actual manufacturing practice when bleaching large quantities of pulp, complete chlorine exhaustion on a large scale could be obtained with about 8—10% concentration in reasonable time, whereas if the concentration was neglected it was very difficult to get complete exhaustion by a considerable amount of agitation in 6 or 8 hours, and certainly not within two hours.

They agreed that the only legitimate use of bleach residual liquors when containing available chlorine was to wash material which had been boiled previously by alkaline treatment, and which received a thorough washing before the actual bleaching was carried out.

The Dobson process was really the revival of an old process. Whilst the concentration was brought to the extreme limit there were grave objections to be urged against that process, one of the chief being that all the residual chemicals had been left in the bleached pulp and all the chlorinated organic compounds, resinous matter, etc., removed from the pulp, which really demanded another process in order to wash them completely out. In the making of high class papers there would be danger of sizing troubles, and generally speaking he thought it was enough to condemn the process in many cases. The use of potassium permanganate presented other difficulties, because the brown oxide of manganese formed required removal by sulphurous acid or some other treatment.

The use of oxygen, in addition to the ordinary hypochlorites, was out of the question on account of cost. He did not see how, at any rate in the paper industry, the erection of electrolytic bleach liquor plant in a paper mill could compete with the ordinary bleaching powder at the price the latter could be bought, because in England they had a highly organised and successful alkali industry and obtained their bleaching powder very cheaply.

R. L. Taylor (this J., 1914, 308) had found that linen did not bleach very well with chlorine water, and that there must be present hypochlorites, and also that there was difficulty with ordinary bleach powder solution, principally due to the presence of free lime; by neutralising the free lime completely or almost completely a very much better result was obtained. In the paper industry where large quantities of linen, cotton, as well as wood pulp were bleached, the matter might be worth further investigation, and at the present time Mr. Jennison and himself were engaged in carrying out some investigations on a manufacturing scale which might possibly be of interest.

He thought Mr. Beadle's suggestion about colour standards was useful. Possibly if the number of standards were increased say from 4 to 6, one could, in specifying a contract, say the pulp should fall within two colours.

Dr. L. T. **Thorne** said that the exact reproduction of conditions in the experiments was of great importance, especially in beating and circulating, because there was present in all these tests an additional influence that was generally neglected, namely, that of atmospheric oxygen. He had carried out extensive experiments on a large manufacturing scale both in cotton and wood pulps of all sorts, by introducing oxygen into the potcher at the same time that the action of the bleaching powder was going on. In some cases 50 tons of paper pulp were experimented on at the time. By introducing oxygen in a fine state of division in the same potcher one could reduce the amount of bleach required by 30% and in some cases nearly 50%, by the use of the oxygen in conjunction with the bleaching powder. Whether it was that nascent chlorine, being liberated from the bleaching powder, rendered the oxygen active, or whether the oxygen was able to oxidise intermediate unstable compounds produced by the bleach from the colouring matters present, it was difficult to say; but there was undoubtedly the fact that if the oxygen were passed into the pulp in the potcher without bleaching powder, there was practically no effect, but if it was passed in whilst the bleaching solution was there and the action was going on, the amount of chlorine or bleaching powder could be enormously reduced. To his mind that was a reason that caused a great deal of difference of opinion where experiments were made on the efficiency of the different bleaches. If experiments were carried out in different potchers the results might be affected owing to the different amount of aeration due to difference in the speeds and the character of the beaters, and so on. The possible action of oxygen should certainly be taken into account in all tests, where comparisons of efficiency of different bleaching materials were being made.

Dr. ERIC RIDEAL asked whether atmospheric oxygen had any effect. They had found that the carbon dioxide had a marked action, but it had been suggested that the oxygen also had an influence. He thought that the question of bleaching fibre had, to a certain extent, been looked at from the wrong point of view. It was not the fibre they wanted to bleach, but the colour of the fibre. These colours were acidic or basic, and in the case of basic colours, one would at least expect the bleach to be slightly acid, while for acid colouring one might reasonably suppose that the bleach should be a little more basic or less acid. He thought it would be rather interesting if, in the case of the coloured fibres used in commerce, the addition of small quantities of alkali or acid would be shown to have any dependence on that fact.

When using liquid chlorine, he had noticed that the corrosion of the reducing valve was a very serious problem, and he did not know of any valve for chlorine which would stand continuous work without giving trouble.

Mr. CLAYTON BEADLE, in reply, said he thought that the beating effect which Dr. Thorne had mentioned must be distinguished from the effect of agitation, because the process of disintegration, which went on all the time during the process of beating, had a very marked effect in accelerating the action of the bleach. Quite apart from the question of more agitation, *i.e.*, the churning effect, the fibre was being reduced and bruised, and that no doubt very much accelerated the process of bleaching. There was a tremendous amount of agitation in the ordinary beater. The roll revolved at a very rapid rate, it was half immersed in the liquid mass of pulp, and it brought a large quantity of air into close contact with the pulp as it travelled round. He thought himself, the oxygen of the air played a very considerable part in the economy as well as the rapidity of the bleach when it was admitted during the process of beating. They had found somewhere between 50 and 60% economy. Inasmuch as every kind of raw material behaved differently, and different kinds of wood pulp also behaved differently, each material might be said to be specialised and required to be studied independently in comparison with other materials. When bleaching, varying bleaching efficiencies had been found for different kinds of chemical pulp, distinguishing sulphides from sulphates and so forth. There was a variation in the rate of bleach and the order in which the various solutions behaved relatively, so it was a very complex problem. He quite agreed with Mr. Baker with regard to the Dobson process. Subsequent treatment was necessary to remove the products. Permanganate bleach had not been mentioned in the paper with the view to suggesting it as a commercial proposition, although it might be on account of the much smaller quantity required in comparison with hypochlorite, but merely as showing that what they called oxygen equivalent varied so enormously in the case of hypochlorites and other oxidising agents which were used for the purpose of bleaching.

Apart from the work Dr. Thorne had done, he did not think any work had been done on the subject of the distinct effect of oxygen as compared with the effect of carbon dioxide. The bleaching process was not entirely a matter of removing the colouring matter; with some materials it was a purification process as well. In most cases when the solution was basic, it was inclined to be sluggish, and when it was acid there was considerable acceleration.

He had visited a mill in Germany where liquid chlorine had altogether taken the place of the hypochlorite bleach: there appeared to be no trouble with regard to the valve, and considerable economy was obtained in point of cost as well as in increased efficiency in comparison with bleaching powder.

APPARATUS FOR THE DRYING OF PAPER FOR TEST PURPOSES.

BY CLAYTON BEADLE AND HENRY P. STEVENS.

As the qualities of paper are largely affected by the method of drying, it is important to imitate in the laboratory as far as possible the methods of drying employed in practice. All papers contract in the course of drying from 5 to 15 per cent., if not kept stretched. If tension is put upon the web, the paper may in some cases actually elongate as in the case of the production of fast running news, where the tension is so great as to render it necessary to run the drying cylinders at a considerably greater speed than the machine wire. If sheets liable to considerable contraction are dried by merely placing in an oven, they become cockled and quite useless.

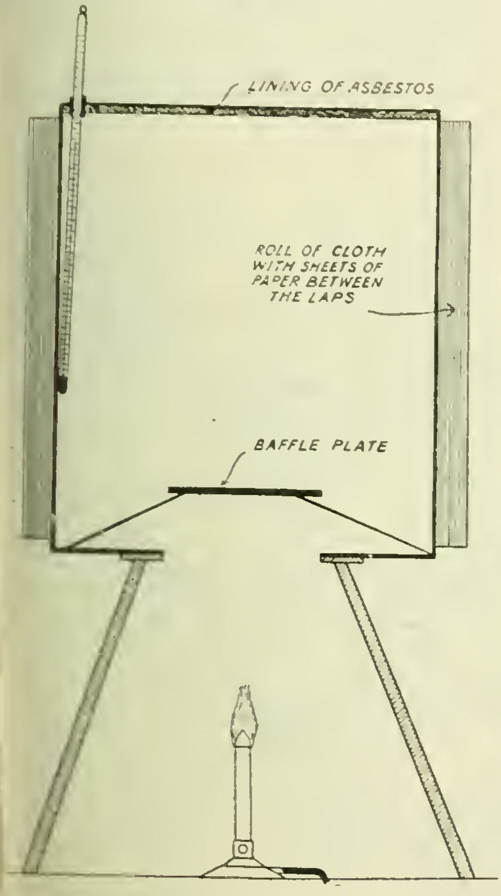
The air drying or loft drying of paper which only slightly contracts is easily imitated on a small scale by hanging the sheets upon a line stretched across the room, but in the majority of tests it is necessary to ascertain what qualities are likely to be obtained by drying under tension in contact with a felt to keep the sheets taut, so as to prevent cockling, this being the method employed in the manufacture of machine-made paper.

To imitate the action of drying cylinders we have employed a hot plate made by fixing a full-sized billiard table-iron in an inverted position over an atmospheric burner consisting of a row of very small gas jets placed at some distance from the plate. With a mercury lute and a thermometer laid down in a convenient position upon the iron, it is possible to record the temperature with a sufficient degree of accuracy to imitate the temperature of the surface of a steam cylinder under any given steam pressure. The sheets of paper are pressed upon the surface of the iron by means of the same kind of felt as is used for the manufacture of the drying felts of the paper machine. By such means the conditions of the machine drying are fairly well imitated but this method entails considerable care and attention to detail, and moreover each sheet has to be dried separately.

We have recently devised a simple apparatus which makes it possible to dry under tension 50 small sheets at a time. When finished they are in much the same condition as they would be if dried over a steam-heated cylinder of a paper machine. This apparatus consists of a cylinder of tin plate, blocked at the top end but with a flange hole at the lower end, and stands upon a tripod. Beneath it is a small Bunsen burner and resting upon the flange is a baffle (see sketch). The heat strikes the baffle and travels upwards to the top and passes downwards along the sides and escapes at the bottom, rising again around the outside. The baffle is so designed as to produce a uniform temperature at top and bottom of the cylinder. Without a baffle the top half is much hotter than the bottom half.

To economise heat, the top of the cylinder can be covered either externally or internally with a sheet of asbestos.

For filling, the cylinder is placed horizontally upon a table and tightly wound with cloth for one and a half revolutions. The sheets of paper are then laid upon the unrolled cloth whilst the cylinder is revolved, keeping the cloth as taut as possible. Finally, the cloth is kept taut by tying tape round near each end of the cylinder. The cylinder is then placed in its position upon the tripod. A hole for the insertion of a thermometer may be placed near the top edge so that the thermometer bulb can be brought in contact with the inner surface of the cylinder and by raising and lowering can be made to indicate the mean temperature. The sheets of paper are dry and ready for removal in about half an hour.



he hot air may be made to escape through holes drilled nd the bottom of the vertical walls but the apparatus wers equally well if no holes are provided, in which case, ourse, the air mostly escapes at the circumference of the b.

convenient sized cylinder is 13 in. long by 10 in. meter, provided with a 6 in. hole. For this sized nder a very small Bunsen with ¼ in. tube without air ulator and flame 2½ in. to 3 in. long is sufficient.

Ve exhibit (*a*) paper made by drying down in oven, (*b*) o air dried on line, (*c*) ditto dried by our apparatus. s from stuff very liable to contraction and cockling. the great difference in the appearance of the sheet is evident.

ting held at Sydney on Wednesday, 19th November, 1913.

MR. LOXLEY MEGGITT IN THE CHAIR.

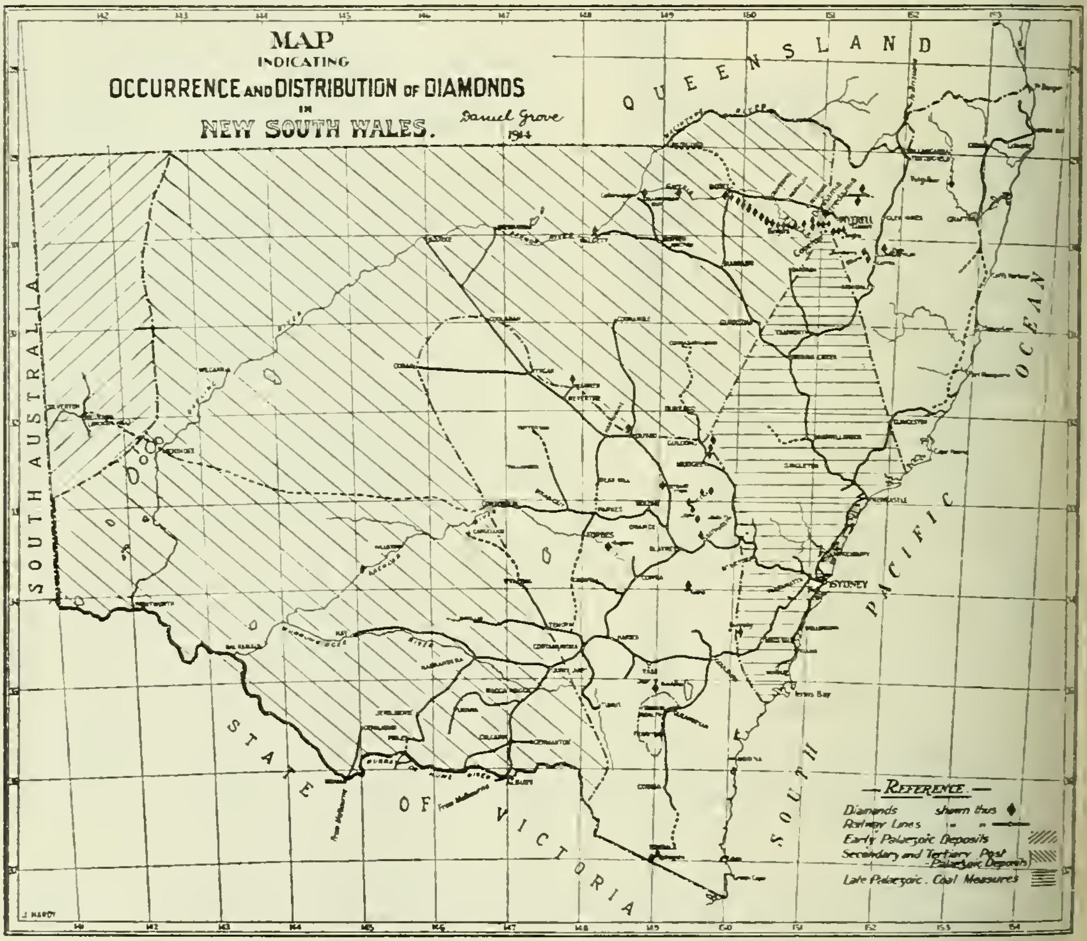
IE OCCURRENCE AND DISTRIBUTION OF DIAMONDS IN NEW SOUTH WALES.

BY DANIEL GROVE.

ie chief Diamond and Gold Fields in South Africa are ed within the 25th and 29th parallels of south latitude. On the East Coast lies the Portuguese Province of Mozambique, containing vast coal measures that extend beyond Middleburg into the Transvaal. The rivers emptying into the Mozambique Channel are (*a*) Post Tertiary and (*b*) Pleistocene, containing gold and tin derived from the Lydenburg and Swaziland Tin Fields, comprising part of the eastern plateau of South Africa. This section embraces pegmatitic granites intersected by diorites and euritic granites veined with quartz and quartzites. Magnetite occurs along the Steelport Valley at Magnet Heights heavily charged with titanium; in that locality no coal occurs, whilst to the South West at the Middleburg Coal Fields chromate of iron occurs in patches as far as the Oliphant River, where tin deposits have been found in a mineralised matrix that belongs to the red granite type of eruptive rocks. Thence to the Premier Diamond Mine near Pretoria, a distance of about 50 miles, are alternate patches of magnetic iron and hæmatite up to within a few miles of Brayton. Twenty miles south is the Witwatersrand gold-bearing conglomerate which extends westward to Potchefstroom and Klerksdorp, which are on the eastern edge of the Upper Karroo Measures. From this western limit to Griqua Town in a westerly line, the whole of the Kimberley diamondiferous pipe and alluvial formation is intersected and embraced. I shall now show the analogy of this to the New England Plateau which forms part of the northern section of the main dividing range of New South Wales. Throughout the length of that section the main divide is dominated by a peneplain structure, namely a plateau of sub-aerial denudation. The drainage of the plateau from Guyra to Maryland and Liston, forming numerous streams that wear away hard and soft rocks, is, in so far as the eastern water shed is concerned, eventually carried out to sea by the Clarence. These waters in their downward career reach the level or inclined surface that slopes gradually from a line somewhat below sea level to a slight altitude inland, forming what is called "base level." A chain of volcanoes extends from Guyra *via* Ben Lomond to a point situated between Tenterfield and Lionsville, the huge flows from which followed the eastern and western water shed, not only filling deep valleys in which were concentrated gold, tin, and other minerals, liberated by erosive agency from their different matrices, but also covering ranges of hills, giving them a "skin" that produces an exceedingly fertile soil. These lava plains are called volcanic plains. I will endeavour to show the importance of the New England Plateau in the whole scheme of diamond and other mineral productions. Our honoured former President, Professor Sir William Crookes, who has made a special study of the diamond, is of opinion that the original matrix was metallic iron in the first place, whilst Professor Bonney states that diamonds have now been traced to two not dissimilar rocks, namely, eclogite in South Africa and dolerite at Oakey Creek in New South Wales. Professor David wrote that "The Oakey Creek Diamond is actually in situ in the hornblende diabase." Mr. Pitman, Government Geologist, New South Wales, wrote that "in view of the authentic occurrence at Oakey Creek, near Inverell, it seems now more logical to search for diamonds in this country in horn-blende diabase rather than in the volcanic breccia containing eclogite boulders."

Following upon the expressed opinions of these scientists, and after numerous conversations with practical diggers on the field, I have made it my duty to ascertain to what extent there exists an analogy between the New South Wales and the South African occurrences and distribution of diamonds. Let us take a section lying between the 29th and 30th parallels of south latitude, and we find in this State that the Clarence River not only contains appreciable quantities of alluvial gold, thereby corresponding with the rivers emptying into the Mozambique Channel, but it has been stated to me by Mr. Alderman that he obtained two beautiful diamonds, small in size, from St. Joseph's Creek, which is a tributary of the Clarence. Again, at Coaldale, about 40 miles from Grafton, I found bituminous coal, corresponding to the coal in the district of Lourenço Marques. At Gordon Brook, along the south bank of the Clarence, rich chromate of iron occurs that corresponds with the Belfast-Middleburg chromates in the

Eastern Transvaal. At Yulgilbar, magnotite, similar to that of Magnet Heights, Transvaal, occurs also containing titanium. At Lionsville, gold is found in rich reefs in diorite and felsite encased in granite somewhat similar to the formation at Moodie's, Transvaal. Near Guyra is situated a crater not inferior in size to any in South Africa, of which the plug or core is undoubtedly dolerite. I have therefore come to the conclusion that the first eruptive rock to intersect that region was the dolerite, and that the general bearing is north and south of all fissures connected with this and other pipes. Recently, upon examining the country between Copmanhurst and Guyra, I found that a very large carboniferous area has been destroyed by these volcanic pipes and fissures, thus corresponding in a remarkable manner with that Eastern portion of South Africa situated between the 26th and 29th par. in south latitude as far as their intersection by the 28th degree of east longitude. In short the 152° of east longitude where it intersects the 29th and 30th parallels of south latitude in this State are as nearly as possible identical in geology and mineralogy with the same latitudinal bearing intersected by the 28° of east longitude in South Africa. In the New South Wales section quoted, only the Ashford Coal Measures to the north of Inverell and the Clarence Coal Measures at and near Coaldale have escaped destruction. Then again, the Cape Free State diamond area quoted is separated from the Great Artesian Water Basin underlying Bechuanaland and Namaqualand by the Upper Karroo beds, just as the Queensland-Northern New South Wales Artesian Wate bearing Basin is separated from the diamond fields b Triassic coal measures called the Western Secondar and Tertiary Beds. There is a noticeable dissimilarit geologically along the respective sections in the matte of erosion. The New England Plateau has yielded t erosive forces at three different periods, the firs synchronising with the doleritic eruptions which penetrate the carboniferous rock; the second dealt with euritic an appelitic granites, quartz, porphyries, felsites, and diorite which pierced the Silurian and Devonian formation bringing with them gold, tin, copper, and other metall ferous minerals; whilst the third era is contemporary wit ourselves in that the basalts and tuffs of the Tert period which cover the two previously mentioned de are now being swept by the board, revealing in many p isolated deposits of diamonds associated with tin other minerals and gem stones. The more notabl these deposits are at present being worked at Sol Hill, the Old Farm, the Mount Ross, the Crown J the Streak of Luck, and the Malacca Tin and Dia Mines situate on the Copeton Diamond Fields. O these mines in particular, called the Round Mount, personally inspected and tested by myself and fou contain excellent white and yellow diamonds of a good I may state that Mr. Cant sold me a parcel of dia taken from this mine which included one weighi carats and one weighing $1\frac{1}{4}$ carats which were of p octahedron shape, spotless and flawless, thus conf



Scale 140 miles to 1 inch.

what has been stated over and over again, that there are diamonds in that region of good commercial size. No similar erosion on anything like the scale exhibited in this State is proceeding between Pretoria and Kimberley in South Africa, for which reason those who are engaged in the local industry must not jump at hasty conclusions. My personal observations are that diamonds have been found not only by Mr. A. R. Pike in the matrix in the Donnamia Mine at Oakey Creek and by myself, but also by my own independent staff of men who were employed to confirm or refute Mr. Pike's remarkable discovery. The specimen of dolerite exhibited this evening is similar to the specimen containing a diamond which Mr. Pike has exhibited to Professors Sir Wm. Crookes and David, among others. The inference, therefore, is that the Inverell Division of New England, where diamonds have been found in the dolerite dyke nentioned, is intersected by a series of dykes running orth and south approximately, and connecting with pipes, t being understood that the subsequent deposition of baalt of the Tertiary period has, in the majority of instances, bscured the pipes, craters, cores and plugs. My men pened the Donnamia Dyke at two levels so as to obtain he exact magnetic bearing, which is 10° west of north by 0° east of south, the thickness of the principal body being 6 ft. 6 in. The matrix, which decomposes on exposure the atmosphere with a facility almost equal to that btaining in connection with the "blue" extracted from outh African pipes, is extremely hard in the lower level. rom nine loads of the decomposed matrix my men btained two beautifully white diamonds which weighed ightly under one carat, unspotted and unfractured.

Mr. Pike and his party indicated to me another matrix rmation at Staggy Creek since called the Alfredamia ine, situated on property owned by Mr. A. F. Kemp Gowrie. The return of 770 diamonds weighing 175 1/32 rats from 200 loads of the overlying alluvial containing uch decomposed dolerite, although satisfactory, does t convey any definite estimate as to the value of the atrix itself. Since that work was carried out, however, have seen several most promising-looking matrix alities in the New England Plateau, and to the south-st of the Donnamia Mine, finding the conditions which I d all along hoped to find, namely, a pipe intact, and a pe that has been deprived of its crater and exterior rock erosion, both containing diamond associates. I have, erefore, been led to believe that a chain of pipes will be nd stretching from the contact of the coal measures at hford with the Secondary Beds along the line of contact, rough Warialda, Bingara, the Copeton Diamond Fields, Narrabri, thence to Boggabri, Gunnedah, Napier, and lgong to Rylstone, as the Western Series, corresponding th the Griqualand West series of pipes in South Africa, ilst an eastern series will most probably be found along New England Plateau between Tenterfield, Deepwater, n Innes, Oban, Guyra, and Walcha, which will respond with the Premier Transvaal Crater and other ters. The Eastern Watershed has undoubtedly iveyed many diamonds and associated minerals to the t into the Clarence Basin, just as the Western Water-d has conveyed diamonds, tin, and other minerals ough Newstead, Elsmore, Gilgai, Toppers Mountain l Stannifer, Tingha, Copeton, into the Gwydir. I her from returns published by the Mines Dept., Sydney, t 178,971⅜ carats of diamonds have been registered the output of this State, valued at £120,407, with an lanatory note that the returns cannot possibly reflect omplete and correct record.

n conclusion I may state that I have not been able to l the matrix of the topaz or wolfram, although I have nd several water-worn pebbles containing half wolfram topaz, thus suggesting that at some spot in the New gland Plateau both occur in situ together.

am referring to the topaz because it is really a most iable associate of the diamond in the alluvial, cutting polishing extremely well, and being saleable in many ntries as a substitute for the diamond itself. The tralian diamonds are hard but extremely fiery when ; in fact, I cannot imagine anything more beautiful rilliant than a cut one-carat stone and upwards from Copeton region set in a lady's pendant or tiara. Carbons or borts are found associated therewith of great hardness and specially adapted as diamond drills. The Government would be exceedingly well advised to equip an expert geological and prospecting expedition to make a systematic investigation throughout the areas referred to in this paper, for certain it is that sooner or later diamonds will be found in the deep alluvial leads of this State and in matrices which will be profitably worked.

From a test working at the Alfredamia mine, Inverell, extending over 230 hours, 200 loads were examined, yielding 770 diamonds which weighed in all 175 carats, and were valued at £150; 80% were white, and 20% yellow; and they were singularly free from carbon spots. Very few were octahedral in shape. The associated minerals were tin (about 1 cwt.), garnet, sapphire, topaz, zircon, and tourmaline.

During my residence on the field a total of 4062 diamonds have passed through my hands, which I have classified as under :—

No.	Colour.	Remarks.	Value per carat.		
			£	s.	d.
2212	Colourless crystals	5% contained black specks	0	16	3
1004	Straw, yellow or bye-waters	20% cleavages or fractured stones	0	10	0
482	Light yellow	2% specks and 3% cleavages	0	13	3
22	Raw siennas		0	10	6
263	Steel grey granulated borts		4	0	0
12	Black borts (Copetonado)		5	0	0
60	Mixed specks and cleavages		0	9	6
3	Blue white		10	0	0
2	Pink		7	0	0
2	Port wine		3	0	0
4062					

The black specks on the colourless crystals were mostly near the surface and could be removed in cutting without much loss. These and the two following lots compared very favourably, weight for weight, with selected Vaal River diamonds. So far there does not appear to be any market in Australia for the borts, for which £4 per carat was paid on the field. These are considered to be equal in value to Brazilian carbonados for use in diamond drills, and should be utilised in Australia, where so much diamond drilling is carried on.

As is well known, Australian diamonds are considerably harder than those from South Africa, hence it would seem that Mohs's scale will require extension to include these stones.

LECTURE ON CATALYSIS.

BY P. SABATIER.

Professor of Chemistry, University of Toulouse.

Abstract of a lecture delivered at King's College, London. Rev. Gén. Chim. Pure et Appl., 1914, 17, 185—193.

Definition.—Catalysis is the name given to certain chemical processes induced by the presence of substances which apparently take no part in the reactions. Thus, hydrogen peroxide in dilute solution decomposes only slowly into water and oxygen; when a little platinum black is dropped in, effervescence takes place, showing the rapidity of the decomposition induced by the platinum black. The latter can be recovered unchanged by filtration and can be used again indefinitely to induce the same decomposition. The platinum black is called the "catalyst."

Commonness of catalytic reactions.—Very many catalytic reactions are known, occurring in all branches of chemistry.

Many reactions resemble catalytic ones in that the presence of substances which are apparently inactive, serves either to accelerate or to retard the change. The reactions include decompositions, as with hydrogen peroxide; combinations, *e.g.*, the union of hydrogen with oxygen, and the direct oxidation of sulphur dioxide induced by spongy platinum, the commercial application of which was suggested half a century ago by the English chemist P. Pelegrin; and double decompositions, such as the formation of esters from alcohols and acids in contact with certain oxides.

Solid catalysts.—Solid, liquid and gaseous substances may act as catalysts. The most numerous catalysts are solids, and include metals, oxides, chlorides and other salts. Since solid catalysts remain unchanged by use, they evidently act only at the surface, and for equal weights, the activity will be in proportion to the area of surface, that is, to the fineness of the particles. Platinum black is more active in proportion to its lightness and porosity. Nickel foil and filings are only slightly active, whilst the activity of finely-divided nickel, prepared by reducing the oxide with hydrogen or carbon monoxide, is very great. Some solid substances, however, only act as catalysts when dissolved, and thus resemble liquid catalysts, the activity being in proportion to the mass present; examples are, iodine in processes of chlorination, and aluminium chloride in the Friedel-Crafts reaction.

Gaseous catalysts.—These are less common than solid or liquid catalysts; their activity is generally in proportion to the mass. Examples are: the action of nitrous vapours in the manufacture of sulphuric acid by the chamber process, and the action of aqueous vapour, the presence of which has been shown by Dixon and Baker to be necessary for the oxidation of hydrogen and of carbon monoxide, and for the combination of gaseous ammonia with hydrochloric acid.

Theories of catalysis.—Berzelius, who first called attention to the phenomenon, offered no real explanation, but suggested that catalysis was due to a change in the polarity of the atoms concerned. The importance of a fine state of division of the catalyst has suggested a physical explanation, long unchallenged. According to this theory, when platinum black is introduced into a mixture of oxygen and a combustible gas (hydrogen, alcohol vapour, etc.), the gases are absorbed rapidly by the porous material which attracts them to its surface, and the gases thus absorbed are subject to increased pressure and a local rise of temperature, both of which conditions assist the chemical interaction of the gases. The products are immediately removed, and replaced by a fresh quantity of the original gases, and so the reaction continues. The heat, set free by compression and by the combination of the gases, accelerates the action, and the platinum may even become incandescent. The function of the catalyst is thus to produce a local increase of pressure and temperature, so as to render possible, apparently at ordinary temperatures, a reaction which normally occurs only at higher temperatures. Ostwald regards the catalyst simply as the accelerator of a possible reaction which would, without the catalyst, take place slowly, and sometimes so slowly as to be incapable of detection. This theory does not offer an explanation as to the attraction of certain gases and not others by the surface of the catalyst; thus, platinum black must be supposed to attract hydrogen and oxygen, but not aqueous vapour. Further, certain catalytic actions are effected by platinum foil or wire, as well as by platinum black. A platinum spiral, heated to expel gases from its surface, and held over methyl alcohol, causes oxidation of the vapour to formaldehyde, the heat generated keeping the metal incandescent. A large sheet of platinum foil, slightly heated and held above an unlighted Bunsen burner causes combination of the gas and air; the foil becomes incandescent and may start a flame. In these cases, the porous solid is not present. Moreover, in the physical conception of catalysis the important differences in the effects of various solid catalysts having the same structure and state of division, are ignored. Zinc oxide and titanic oxide are physically similar but act very differently on formic acid vapour at 300° C. With zinc oxide, equal volumes of carbon dioxide and hydrogen are formed, whilst with titanic oxide, water and carbon monoxide alone are produced. The physical explanation of catalysis is not applicable to liquid and gaseous catalysts which form a homogeneous mixture with the reacting substances. A rational theory of catalysis must be based on the chemical action of the catalyst which can unite with some of the reacting substances to form an unstable intermediate compound.

Reciprocal catalysis.—Two chemical systems, which are themselves stable though capable of undergoing change, such as hydrogen peroxide, and chromic acid solution mixed with sulphuric acid, will, when mixed, act catalytically one on the other, the two changes taking place simultaneously in identical proportions. The hydrogen peroxide and chromic acid are both decomposed, and the same quantity of oxygen is generated from each. This indicates that the cause of the decomposition is the formation of an unstable compound of 3 mols. H_2O_2 and 2 mols. CrO_4H_2. This compound is decomposed as quickly as it is formed, into free oxygen, water and chromium sesquioxide which dissolves in the sulphuric acid. This intermediate compound can be isolated by suitable means. When dilute solutions are used, instead of oxygen being evolved, a blue liquid is produced. The blue substance can be extracted with ether, and isolated by evaporating at —20° C. At the ordinary temperature this substance decomposes into oxygen, water, and chromium sesquioxide. A similar example is the interaction of hydrogen peroxide and potassium permanganate, and the existence of an intermediate unstable compound must be assumed in this case also.

Ordinary catalysis.—By analogy, it may be concluded that the catalyst combines rapidly with one of the substances present, and the compound formed reacts quickly with the other substances, setting free the catalyst which can act again in the same manner indefinitely. The intermediate compounds can sometimes be readil detected, when they are stable at some other temperatur than that of the catalytic reaction. This is the cas in the production of ether or of ethylene from alcoho by means of sulphuric acid. Concentrated sulphuri acid combines with alcohol to form ethyl-sulphuric acid :—

$$C_2H_5.OH+SO_4H_2=SO_4H.C_2H_5+H_2O.$$

If the liquid be kept cold, no further change occur On heating to 60° C. in the presence of an excess o alcohol, the latter reacts on the ethyl-sulphuric acid t give ether, which distils off, and sulphuric acid whic again combines with alcohol :—

$$C_2H_5.OH+SO_4H.C_2H_5=(C_2H_5)_2O+SO_4H_2,$$

the sulphuric acid thus acting as catalyst in the reaction :—

$$2(C_2H_5.OH)=H_2O+(C_2H_5)_2O.$$

A small quantity of acid can in this way transfor a large quantity of alcohol into ether. If the liquid quickly heated to over 150° C., the reaction is differen The ethyl-sulphuric acid is decomposed with formation ethylene and sulphuric acid :—

$$SO_1H.C_2H_5=C_2H_4+SO_4H_2.$$

The acid thus formed acts again in the same way, servi as catalyst in the reaction :—

$$C_2H_5.OH=C_2H_4+H_2O.$$

The intermediate compound in both of these reactio is easily detected, since it is stable at a lower temperatu Another example is furnished by Squibb's method the production of acetone. The vapours of acetic acid a passed over calcium carbonate at 500° C. The init reaction is evidently the formation of acetate :—

$$CaCO_3+2(CH_3CO_2H)=CO_2+H_2O+(CH_3CO_2)_2Ca.$$

Below 400° C., the reaction produces calcium acetate whi is stable at that temperature, but at 500° C. the acet is decomposed into acetone and calcium carbonate :—

$$(CH_3.CO_2)_2Ca=CaCO_3+CH_3CO.CH_3,$$

and a small quantity of calcium carbonate can thus cha any quantity of acetic acid into acetone. In both th examples, it is impossible to overlook the intermedi compound which serves as a step in the reaction. J usually the intermediate compound cannot be detected with certainty because it is not sufficiently stable at any temperature to be isolated. This is the case in most of the catalytic reactions induced by platinum or finely divided metals. But some idea of what occurs can be formed by analogy. Platinum black, when introduced into a mixture of alcohol vapour and air, fixes oxygen on its surface in the form of a true chemical compound, such at PtO, and the oxide reacts immediately with the alcohol vapour to form aldehyde, the platinum being set free and acting again in the same way indefinitely. Similarly, reduced nickel placed in a mixture of hydrogen and benzene vapour, fixes hydrogen on its surface in the form of a thin layer of an unstable hydride, such as NiH_2. At a suitable temperature, about 180° C., this hydride reacts immediately with the benzene vapour, forming cyclohexane, and the nickel is regenerated and acts again in the same way.

Reversible catalysis.—It frequently happens that the unstable intermediate compounds formed by the catalysts can determine the reaction in either direction. Thus, platinum black absorbs free oxygen and yields it again immediately to oxidisable substances, but it can also, by virtue of the same affinity, take oxygen from substances capable of readily losing it. When platinum black is dropped into hydrogen peroxide, the platinum immediately takes up oxygen, forming the unstable oxide, which decomposes at once. Platinum black thus acts as catalyst in processes involving the addition or the removal of oxygen, according to circumstances. Finely divided copper or nickel placed in an atmosphere of hydrogen, fix the gas temporarily and pass it on to other substances. Conversely, in the presence of substances capable of giving up hydrogen, these metals take up hydrogen, which is immediately set free Thus aldehydes passed with excess of hydrogen over nickel below 200° C. form the corresponding primary alcohols. Conversely, the vapours of the primary alcohols, passed over nickel at 250° C. are decomposed into aldehydes and hydrogen. Cases of this kind are very numerous. In conjunction with Mailhe the author has shown that the vapour of phenol when passed over thoria at 450° C. loses water and is converted into phenyl ether Later, the author and Espil showed that a mixture of phenyl ether and water vapour, passed over thoria at 450° C. readily forms phenol. The two reactions occurring at the same temperature necessarily do not proceed to completion. A similar inversion of the effect of the catalyst is often met with. The recent researches of Bourquelot have shown that emulsin, a soluble organic catalyst, not only effects hydrolysis of glucosides, but can very often lead to the formation of the same glucosides by dehydration.

Influence of the mass of the catalyst.—The catalyst thus appears to play an active part in the reactions which it determines. The temporary combination of the catalyst with one of the reacting substances makes the reaction possible, and a small amount of the catalyst can change a arge quantity of the reacting substances, because the catalyst is regenerated by the rapid decomposition of the ntermediate compound. There is thus no definite relation between the mass or the active surface area of the catalyst and the weight of the substances which it can produce. The reactions will, however, be more rapid as the quantity of catalyst is greater. Their velocity will be, in some degree at least, proportional to the mass of the catalyst n a homogeneous system, or to the surface in the case of olid catalysts which act only at their surface.

This chemical conception of catalysis has led the author ith his pupils to the discovery of new facts, which may e grouped under two headings, catalysis (1) by metals nd (2) by oxides.

CATALYSIS BY METALS.

In a series of researches extending over nearly years, in collaboration with Senderens, Mailhe, urat, and Espil, it has been shown that the common etals iron, copper, cobalt, and especially nickel, a fine state of division such as is produced in the duction of the oxides by hydrogen, carbon monoxide, alcohol vapour, form very active catalysts in processes of adding or withdrawing hydrogen, and in molecular decompositions.

Addition of hydrogen by means of nickel.—The catalytic action of finely divided platinum had been used chiefly for effecting oxidation. Only in few cases had its power of effecting the addition of hydrogen been recognised. These were the conversion of nitric oxide into ammonia (Kuhlmann, 1838), the rapid combination of iodine with hydrogen (Corenwinder, 1852), the conversion of hydrocyanic acid into methylamine (Debus, 1862), and the production of ethane from acetylene (de Wilde, 1874). In 1897, the author discovered with Senderens, that in the presence of reduced nickel, free hydrogen at a very low temperature can rapidly change ethylene into ethane, and it has since been shown that this catalytic action of nickel is quite general and is capable of effecting the addition of hydrogen not only in known reactions usually carried out by means of ordinary reducing agents (zinc and hydrochloric acid, sodium amalgam and water, concentrated hydriodic acid, etc.), but also in other reactions which could not be effected by the old methods. The method employed for volatile substances is very simple; it is only necessary to pass them together with hydrogen in excess through a column of reduced nickel kept at a suitable temperature. In this way, nitro-compounds can be converted into amines, *e.g.*, nitrobenzene into aniline. Ethylenic and acetylenic compounds are readily converted into saturated compounds. Aliphatic aldehydes and ketones yield the corresponding alcohols, and amines are readily obtained from nitriles, oximes and amides. Carbon monoxide and dioxide are converted into methane, and this may possibly be the basis of an important commercial process for manufacturing from water-gas or coal-gas a lighting gas rich in methane and having a high calorific power. The most valuable application of the new method is the formation of cyclohexane derivatives by the addition of 6 atoms of hydrogen to the benzene nucleus. By simply passing benzene vapour with hydrogen over reduced nickel at 180° C., the benzene is completely converted into cyclohexane. In the same way, phenol is converted into cyclohexanol, and aniline into cyclohexylamine. In conjunction with his pupils, the author has shown the addition of hydrogen to aromatic compounds by means of nickel to be almost general, and this should form the starting point for important synthetic manufacturing processes. Thus, the *p*-cyclohexanol formed from *p*-cresol may serve as the raw material for the manufacture of caoutchouc. Hydrocarbons with multiple or complex nuclei, naphthalene, anthracene, phenanthrene, terpenes, etc., can also be caused to combine with hydrogen by means of reduced nickel.

Conditions necessary for the addition of hydrogen.—Certain conditions are essential for the success of the process. The temperature must be kept within certain limits, which are wide in some cases, as with nitro- and ethylenic compounds, but narrow in others. The reduction of benzene cannot be effected above 250° C.; at higher temperatures cyclohexane loses hydrogen. The best temperature is usually about 180° C. The catalyst should be prepared in the reaction tube itself, by reducing with hydrogen an oxide as free as possible from chloride and sulphate. The oxide obtained by calcining at dark red heat nickel nitrate prepared from commercial nickel and nitric acid is generally used. The nickel is more active the lower the temperature at which it is prepared, and the lighter the oxide from which it is formed. The metal obtained by reducing the green hydroxide below 300° C. is exceedingly active and often causes molecular changes in compounds subjected to catalysis. Nickel reduced above 750° C. will not convert benzene into cyclohexane, but will change nitrobenzene into aniline. An essential condition is the conservation of the catalyst, the activity of which may be spoiled by impurities in the hydrogen or in the reacting substances. Chlorine, bromine, iodine and sulphur are specially harmful in the case of nickel. In conjunction with Espil, the author has recently shown that the humidity of the hydrogen has no unfavourable effect, and is favourable in certain cases. But while it is useless to dry the gas, it is necessary to purify it thoroughly. This may be done by passing it over copper turnings heated to dull redness and then over moist potash. It has been supposed that traces of chlorine, bromine, iodine or sulphur would immediately render the nickel inactive, but this is not the case. Benzene containing 0·5% of iodine can be converted into cyclohexane, and during an experiment lasting several hours, 150 c.c. of the solution was treated. On breaking the tube, the first half of the column of nickel was found to have taken up iodine and was inactive, and the second half was unaltered and was capable of continuing the reaction. Thus the destruction of the catalyser by iodine took place slowly through successive layers, and in the actual experiment 250 c.c. of cyclohexane could have been obtained before the tube became inactive. A similar result was obtained with benzene containing 10% of carbon bisulphide.

Addition of hydrogen in a liquid medium.—Reduced nickel effects the combination of hydrogen with numerous substances, which need not necessarily be in the gaseous state. When a current of hydrogen is passed through a fatty oil, such as earthnut (arachis) oil at 180° C., in which reduced nickel is suspended, the oleic esters are converted into stearic esters and the reaction is completed in a few minutes. The oil changes to a fat, which solidifies on cooling. This conversion of oils into fats is usually accompanied by deodorisation. It is now the object of important industrial applications.—A. T. L.

Journal and Patent Literature.

Patent Specifications may be obtained by post by remitting as follows :—

English.—8*d.* each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane, London, W.C.

United States.—1*s.* each, to the Secretary of the Society.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.); Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—GENERAL PLANT ; MACHINERY.

Patents.

Steam ; Generation of ——. C. D. McCourt, Streatham Common, and Bonecourt Surface Combustion, Ltd., London. Eng. Pats. 11,958 and 11,959, May 22, and 26,255, Nov. 15, 1913.

Liquid or semi-fluid fuel is fed into a heated chamber, with a regulated supply of air. The liquid is volatilised and partially burned in this chamber and the mixture of air and gas or vapour passes into a chamber fitted for surface combustion, or into tubes filled with lumps of porous refractory material.—W. H. C.

Steam ; Generation of ——, *feed water heating, and the heating of liquids.* P. St.-G. Kirke and Bonecourt Surface Combustion, Ltd., both of London. Eng. Pat. 26,769, Nov. 21, 1913.

Heating tubes are provided with refractory material for promoting surface combustion, and with a further quantity of refractory material, through or over which the combustion products pass so that their heat is transmitted rapidly to the liquid. The first part of the tube forms a mixing chamber for the air and gas, in which combustion begins, so that the gases need not be forced through the refractory material at a speed greater than that of propagation of the flame, and a lower pressure can be used. The front end of the mixing chamber is open to the air and one or more gas-supply nozzles are arranged to deliver into the open end. A refractory sleeve in the mixing chamber forms a restricted outlet for the partly burnt gases. (See also Eng. Pats. 29,430 of 1909, 4362 of 1910, and 11,958 of 1913 (this J., 1910, 1448; 1911, 406 and *supra*).—A. T. L.

Evaporating frothing liquids ; Apparatus for ——. F. Seeger, Magdeburg, Germany. Eng. Pat. 12,265, May 26, 1913.

The vapour and froth pass from a tubular evaporator first into a froth chamber situated above and thence through a turbine separator into the first separating chamber where the froth bubbles are broken up owing to the lower pressure which exists in this chamber. The vapour then passes through an impact separator into a second separating chamber and thence to a third from which it passes to the condenser.—W. H. C.

Evaporators ; Process for supplying liquid to —— *in which the liquid is circulated.* A.-G. für Vakuumverdampfanlagen. Ger. Pat. 274,153, July 23, 1911.

The liquid is injected directly into the lower ends of the heating tubes from nozzles fitted in a system of concentric or parallel supply tubes. Or, the liquid-supply pipe, mounted so that it can be rotated, may be provided at its upper end with branch tubes fitted with nozzles, which come in turn below the heating tubes as the liquid-supply pipe is rotated.—A. S.

Fractionising and cooling the constituents of products of distillation, boiling at higher temperatures ; Process for —— *and condensing apparatus for carrying the process into effect.* J. Fischer, Vienna. Eng. Pat. 21,928, Sept. 29, 1913.

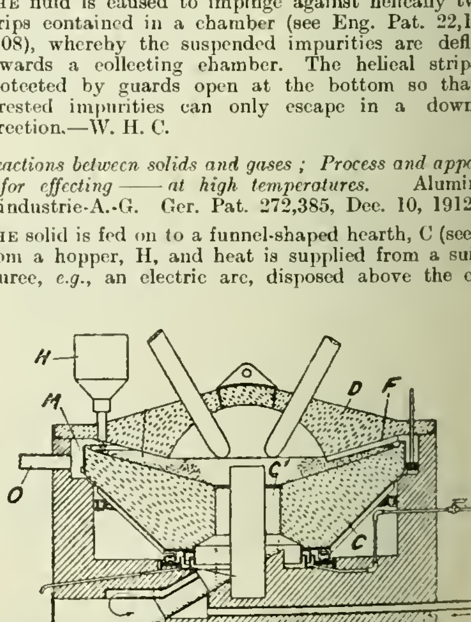
The vapours are cooled by the condensed liquid which is caused to flow back for this purpose through alternate cells of suitable plate condensers.—W. H. C.

Separators for removing impurities from fluids. W. H. Yardley, Sheffield. Eng. Pat. 22,120, Oct. 1, 1913.

The fluid is caused to impinge against helically twisted strips contained in a chamber (see Eng. Pat. 22,184 of 1908), whereby the suspended impurities are deflected towards a collecting chamber. The helical strips are protected by guards open at the bottom so that the arrested impurities can only escape in a downward direction.—W. H. C.

Reactions between solids and gases ; Process and apparatus for effecting —— *at high temperatures.* Aluminium-industrie-A.-G. Ger. Pat. 272,385, Dec. 10, 1912.

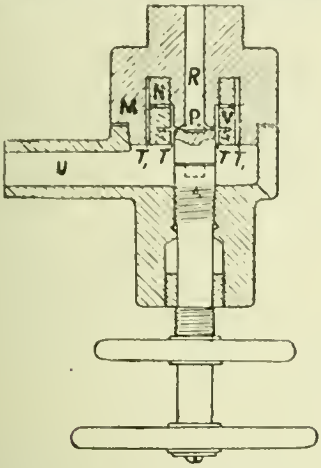
The solid is fed on to a funnel-shaped hearth, C (see fig.), from a hopper, H, and heat is supplied from a suitable source, *e.g.*, an electric arc, disposed above the centre of the hearth. The hearth rotates about its vertical axi and the charge gradually moves in a spiral path fro



the outer edge to the centre, being spread out as a thin layer by ribs, F, projecting from the roof, D. The gases are supplied to the central opening, C^1, flow outwards, over the charge on the hearth, to the annular channel, M, and are discharged through O.—A. S.

Liquids ; Process for rendering —— homogeneous. F. M. Berberich. Ger. Pat. 273,917, Dec. 1, 1912. Addition to Ger. Pat. 269,540.

A modified form of the apparatus described in the principal patent (this J., 1914, 302). The liquids are supplied under pressure through the channel, R, and pass, on the one hand through the annular passages, P_1, and T, and, on the other hand, through M and T_1, into the outlet pipe, U. Part of the liquid is forced into the *culs-de-sac*, V and N, and in returning therefrom is intimately mixed with liquid flowing in the opposite direction.—A. S.



Purifying and cooling hot gases ; Process and apparatus for —— and the condensation of vapours. G. F. Jaubert, Paris. Eng. Pat. 14,420, June 21, 1913. Under Int. Conv., June 22, 1912.

See Fr. Pat. 456,580 of 1912 ; this J., 1913, 1095.—T. F. B.

Gases or vapours ; Apparatus for treating —— with liquids. I. Moscicki, Freiburg, Switzerland. U.S. Pat. 1,097,870, May 26, 1914. Date of appl., April 27, 1909.

See Fr. Pat. 403,401 of 1909 ; this J., 1910, 76.—T. F. B.

Gases ; Apparatus for the chemical transformation of —— by multiple-contact action at regulatable temperatures. T. Wolff, Leverkusen, Germany, Assignor to General Chemical Co., New York. U.S. Pat. 1,099,530, June 9, 1914. Date of appl., Jan. 16, 1913.

See Fr. Pat. 453,470 of 1913 ; this J., 1913, 741.—T. F. B.

Extraction apparatus. H. A. Gill, London. From Harburger Eisen- und Bronzewerke A.-G., Harburg, Germany. Eng. Pat. 27,014, Nov. 24, 1913.

See Fr. Pat. 465,640 of 1913 ; this J., 1914, 633.—T. F. B

Separating fine-grained admixtures from slimes ; Apparatus for ——. A. Freygang, Hamburg, Germany. U.S. Pat. 1,097,855, May 26, 1914. Date of appl., Nov. 6, 1912.

See Eng. Pat. 25,548 of 1912 ; this J., 1913, 221.—T. F. B

Furnace with regenerative firing. K. Wendt, Assignor to Georgs-Marien-Bergwerks- und Hütten-Verein, Georgsmarienhütte, Germany. U.S. Pat. 1,097,900, May 26, 1914. Date of appl., Dec. 14, 1911.

See Ger. Pat. 258,147 of 1910 ; this J., 1913, 540.—T. F. B.

Furnaces ; Refractory lining for ——. O. Serpek, Assignor to Soc. Générale des Nitrures, Paris. U.S. Pat. 1,099,131, June 2, 1914. Date of appl., Jan. 26, 1912.

See Fr. Pat. 436,596 of 1911 ; this J., 1912, 499.—T. F. B.

Furnace provided with regenerative chambers. H. Poetter, Düsseldorf, Germany. U.S. Pat. 1,100,985, June 23, 1914. Date of appl., Dec. 22, 1913.

See Eng. Pat. 26,411 of 1913 ; this J., 1914, 408. -T. F. B.

Mixing powdered substances or highly concentrated solutions with a liquid or dissolving them in the latter ; Process of and apparatus for ——. W. Loebel, Leipzig, and K. Franz, Frankfort, Germany. U.S. Pat. 1,098,811, June 2, 1914. Date of appl., Dec. 11, 1911.

See Eng. Pat. 20,585 of 1912 ; this J., 1913, 740.—T. F. B

Drying apparatus ; Vacuum ——. A. Ravautte, Assignor to A. Ravautte, Marseilles, E. C. A. Fleurent, and Soc. Anon. des Etabl. Egrot, Paris. U.S. Pat. 1,100,028, June 16, 1914. Date of appl., Feb. 24, 1912.

See Fr. Pat. 428,374 of 1911 ; this J., 1911, 1147.—T. F. B.

Grading finely-divided materials ; Method of and apparatus for ——. H. K. Hitchcock, Tarentum, Pa. U.S. Pat. 1,100,302, June 16, 1914. Date of appl., June 7, 1912.

See Eng. Pat. 1212 of 1913 ; this J., 1913, 587.—T. F. B.

Smoke ; Apparatus for cleaning ——. J D. Jackson, Kensington, Victoria. U.S. Pat. 1,100,307, June 16, 1914. Date of appl., Aug. 26, 1913.

See Eng. Pat. 4636 of 1913 ; this J., 1914, 341.—T. F. B.

Melting and projecting fusible substances ; Apparatus for ——. E. Morf, Zürich, Switzerland. U.S. Pat. 1,100,602, June 16, 1914. Date of appl., Sept. 20, 1913.

See Eng. Pat. 28,001 of 1912 ; this J., 1913, 792.—T. F. B.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Methane ; Limits of inflammability of ——. F. Leprince-Ringuet. Comptes rend., 1914, **158**, 1793—1796.

An empirical expression is deduced showing the effects of water content and temperature on the limit of inflammability of methane and air. It is also shown that ordinary atmospheric fluctuations of pressure have little effect. The diameter of the explosion tube has a distinct effect (*e.g.* in a 5·15 mm. tube the limit was 6·95% while in an 8·15 mm. tube it was 6·17%). The direction of the explosion (from above or below) may also cause the results to vary considerably (*e.g.* from above 5·76% to below 5·20%).—W. H. P.

Coal gas ; Synthetic preparation of ——. L. Vignon. Comptes rend., 1914, **158**, 1809—1811.

The author has attempted to devise a scheme for the gasification of the whole of the carbon of coal to produce a combustible gas with a low percentage of carbon monoxide and possessing the calorific power of ordinary coal gas. Making use of reactions previously studied (this J., 1911, 121 and 488 ; 1913, 76, 742 and 817) he suggests various technical processes starting from water-gas, coke, or coal. Lime is added to the coal, and the whole distilled at 900°—950° C., 100 kilos. of coal giving about 25 cb. m. of rich gas. Then water vapour is passed over the coke and lime at 900°—1000° C., which brings up the yield to about 200 cb. m. of a gas containing: H_2 70—78, CH_4 15—20, CO 5—10%. The amount of carbon monoxide may be reduced even further if necessary. The calorific value of such a gas is only slightly inferior to that of coal gas. The volume obtained is 8—10 times greater than that obtained by simple distillation and practically all the nitrogen is converted into ammonia.—W. H. P.

[Gas] Purification by heat. C. C. Carpenter. J. Gas Lighting, 1914, **126**, 928—938.

The presence of carbon bisulphide in coal gas was first demonstrated by Lewis Thompson, and the proposals for the removal of sulphur compounds other than hydrogen sulphide by the aid of heat are based on the reaction: $CS_2+2H_2=2H_2S+C$. With pure materials the amount of carbon deposited is exactly proportional to the carbon bisulphide decomposed, and the reaction has been used for determining the content of carbon bisulphide in coal gas. In the original test of Vernon Harcourt the gas was passed through an inverted Florence oil flask filled with pebbles and heated by a gas burner. Later, an active contact substance—platinised pumice—was substituted for the pebbles, whereby it became possible to use a small bulb in place of the large Florence flask.

Efficiency of certain catalytic and contact substances with increasing temperatures.

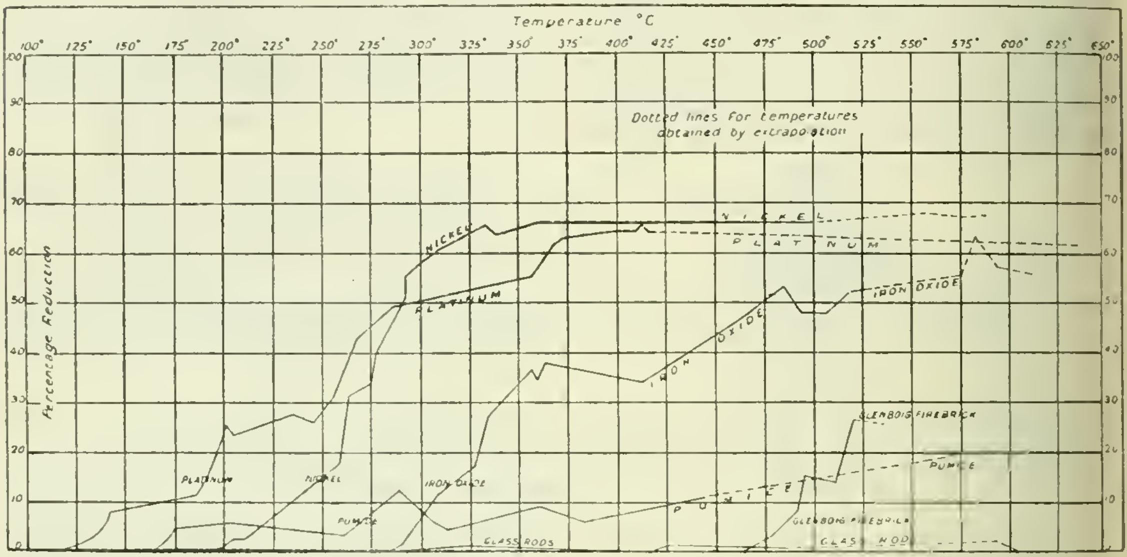


FIG. 1.

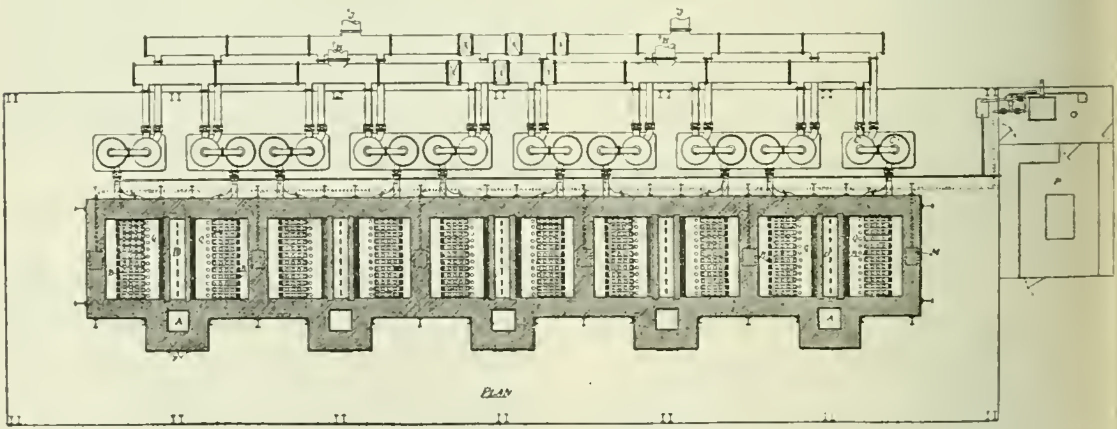
Starting from a patent taken out by E. Heard in 1806, many proposals have been made for purifying coal gas by the action of heat, usually in presence of a contact substance, but none of the earlier processes proved successful on the large scale, owing mainly to difficulties in connection with the apparatus or to undue reduction of the illuminating power of the gas. The first successful application of purification by heat on a commercial scale was effected by Hall and Papst in the United States, a plant being put into successful operation in August, 1908, at Portland, Oregon. A pair of superheaters filled with chequer-work as in a water-gas plant, was used, with a gas producer in between. The superheaters were heated alternately by gas from the producer. The gas to be purified was passed through one of the superheaters whilst the other was being heated, and when the first superheater had cooled to such a degree that it was no longer sufficiently effective, the flow of gas was diverted to the second superheater and producer gas led into the first to heat it again to the requisite temperature. With this installation, during twelve months (1909), the sulphur content was reduced from 49·0—68·9 (average 58·83) to 14·2—20·8 (average 16·94) grains per 100 cb. ft., the percentage reduction being 63·21—75·85 (average 71). The total gas treated during the year was 817 million cubic feet, with a maximum of 4 million cb. ft. per day, and the average cost, including fuel, labour, repairs, and investment, was ½d. per 1000 cb. ft. The percentage reduction of sulphur at different temperatures was: 427° C., 20·7; 454°, 36·6; 482°, 50·8; 510°, 57·8; 538°, 62·7; 566°, 66·4; 593°, 68·8; 621°, 71·2; 649°, 72·9; 677°, 74·5; and 704° C., 76·0%.



A Furnace. B. Tubes containing Catalyst C. Heat Interchangers D Combustion Chamber H Gas after Treatment J Gas before Treatment M Chimney
O. Aeration Plant P Test Room Q Heating Chamber.

FIG. 2.

The author's experiments began in 1906, and from 1908 onwards numerous tests of the efficacy of various catalysts under different conditions were carried out. Some of the results (percentage reduction of sulphur) obtained with different contact substances under constant conditions in regard to rate of flow of gas are shown in the curve-diagram (see Fig. 1). For work on a large scale, reduced nickel was found to be the most satisfactory catalyst and the highest temperature which could be used, compatible with the maintenance of the quality of the gas and the durability of the iron container, was 400°—500° C. An essential feature of the process is the preheating of the gas before it enters the reaction tubes containing the catalyst; otherwise such a furnace temperature is required to maintain the catalyst at the requisite temperature that the tubes are speedily destroyed. The plant now installed in the East Greenwich works of the South Metropolitan Gas Company is shown in plan in Fig. 2. It consists of five units each capable of dealing with 3 million cubic feet of gas per day. Each unit comprises a producer, A, and a combustion chamber, D, on either side of which are heating chambers, Q, containing the reaction tubes, B. The gas, freed from hydrogen sulphide, flows through the pipe, J, into the heat interchangers, C, C′ (wrought-iron vessels filled with 3-inch tubes; one efficiently jacketed and the other with bare walls, so that the temperature of the gas can be controlled). The gas is preheated by the waste gases from the heating chambers which flow through the heat-interchangers in the opposite direction. It then passes through the heating chamber and next flows in parallel currents through the reaction tubes, packed with the catalyst, to a collecting main, whence it flows through the heat-interchangers in the opposite direction to the incoming gas, and thence to the secondary purifiers for the removal of hydrogen sulphide. At O is the aerating plant comprising a small gas-engine driving a fan, by means of which air can be passed through the reaction tubes to burn away the deposited carbon. The results obtained on the large scale with this installation have already been given (see this J., 1914, 682).—A. S.

Viscosity of mixtures of mineral oils; Simple method of calculating the ——. E. Molin. Chem.-Zeit., 1914, **38**, 857—859.

The viscosities of mixtures, in different proportions, of a refined Russian oil of sp. gr. 0·912 and viscosity (Engler) 67·4, and an American spindle oil of sp. gr. 0·868 and viscosity 2·5, were determined and from the results a curve was plotted and a table constructed showing the change in viscosity with increasing percentages (by vol.) of the more viscous oil. The curve or table was then used for calculating the viscosity of mixtures of mineral oils of known viscosities, each component oil being regarded as a mixture of the two oils of viscosity 67·4 and 2·5 respectively, in certain proportions as ascertained from the table, and the composition of the original mixture then calculated in terms of these two oils, and the viscosity of such a mixture read from the curve or table. The method proved satisfactory with mixtures of oils of widely different viscosities. The formula proposed by Pyhälä (this J., 1912, 18) gives satisfactory results only in cases where the viscosity of one component is very low (about 1° Engler), or where the viscosities of the two components do not differ widely.—A. S.

Naphthenic acids of high molecular weight in Baku petroleum oil. E. Pyhälä. Z. angew. Chem., 1914, **27**, 407.

The acids in the waste lyes from the refining of Baku machine oils were liberated, washed, dried and distilled *in vacuo*. The distillate was extracted with alcoholic potassium hydroxide, the alcohol evaporated from the extract, and the naphthenic acids liberated from the soap. The product was a light yellow, nearly odourless, and very viscous oil with a neutralisation value of 100. When dissolved in ether, shaken with concentrated hydrochloric acid, and washed with water, it left (after evaporation of the ether) a residue which on fractional distillation yielded the two acids previously described (this J., 1914, 634). Both fractions had the typical naphthenic odour, but hardly perceptible when cold.—C. A. M.

Asphaltum; Navaho ——. T. Rosenthal. Z. angew. Chem., 1914, 27, 422—424.

Navaho-asphaltum is obtained from a viscous crude oil from wells in South California. The crude oil is separated from water and earthy matter and is then heated, to a temperature depending on the hardness desired, in order to remove the lighter oils, the residue of asphaltum being the only product recovered. The asphaltum has a sp. gr. greater than 1 at 25° C., loses 0·1% on heating for 7 hours at 163° C. (compare this J., 1911, 201), and contains: ash 0·2, organic non-bituminous substances 0·3, and bitumens soluble in petroleum-spirit (sp. gr. 0·725) 87·8, in carbon bisulphide, 99·5 and in carbon tetrachloride, 98·5%. It contains no paraffin and only traces of sulphur. Its superiority to some other asphaltums is shown by the following figures:—

Kind of asphaltum.	Bitumen.	Ash.	Organic non-bitumen substances.	Ductility.*
	%	%	%	cm.
Navaho	99·52	0·17	0·31	100
Bermudez	93·88	1·67	4·45	52
Trinidad	57·03	36·49	6·48	37

* See Dow, Proc. Amer. Soc. Testing Materials, 1903, Vol. 3.

It is used, without any addition of fluxing materials, for paving, for insulating and for making roofing sheets. —A. T. L.

Asphaltum: Chemistry and analysis of ——. J. Marcusson. Chem.-Zeit., 1914, **38**, 813—815, 822—823. (See also this J., 1913, 223.)

The author's method of differentiating natural and oil asphaltums (Chem.-Zeit., 1908, 965; compare this J., 1911, 480) has been criticised by Loebell (Chem.-Zeit., 1914, 18) and by Kantorowicz (this J., 1914, 66), but it is pointed out that if petroleum benzine does not precipitate the whole of the asphaltic substances, they will be separated in the subsequent treatment with sulphuric acid. *Saponifiable constituents of natural asphaltums.* On treating asphaltum with benzene, adding alcohol, and titrating the benzene-alcohol extract with alkali, neutralisation values of 15·4 to 2·8 were obtained, the highest being given by Trinidad and Bermuda asphaltums and the lowest by asphaltum meals, in which the acids were partly in combination with lime. Crude petroleum oils and distillation residues gave neutralisation values of less than 1. After purification, bitumens gave lower values than before (*e.g.*, 6·9 as compared with 15·9), this being attributable to the formation of acid anhydrides or lactones during the heating. The examination of "trinascol," or Trinidad crude oil (an intermediate step in the formation of Trinidad asphaltum) also indicated that the saponifiable constituents of natural asphaltums are not fatty or wax esters. A sample of trinascol (a black viscous mass smelling of sulphur compounds) contained 3·9% sulphur, and 0·5% paraffin wax in the oily constituents. The saponification value was 9·4 (Trinidad asphaltum, 34) and the acids separated amounted to 3·1% (Trinidad asphaltum, 13%). The asphaltic acids from Trinidad asphaltum were very similar to the polynaphthenic acids obtained by heating Texas oil for about 70 hours at 120° C., both being nearly insoluble in petroleum benzine.

Acids from—	Acid value.	Saponif. value.	Iodine value.	Sulphur.
				%
Trinidad asphaltum	98·5	120·4	22·4	3·1
Texas oil	89·3	147·0	17·3	1·2

After longer heating at 120° C. the acid value of both asphaltic and petroleum acids decreased (*e.g.*, from 104 to 74), apparently owing to the formation of anhydrides. *Asphaltites* can be readily distinguished from friable petroleum distillation residues by their low oil-content. Petroleum residues contain over 20% of semi-solid oil (unaffected by sulphuric acid) in which is over 2% paraffin wax, whilst the oily portions of asphaltites are fluid and nearly free from paraffin wax. The following results were obtained :—

Asphaltite.	Acid value.	Sulphur.	Oily constituents unaffected by H_2SO_4
	%	%	%
Syrian asphaltum	0·5	8·9	1·4
Gilsonite (Utah)	0·5	0·5	6·7
Grahanite (W. Indies)	0·1	3·7	3·3
Albertite (Nova Scotia)	0·2	0·44	1·7
Manjak (Barbados) ..	2·4	1·5	0·17

Manjak, which is the softest of all asphaltites, is regarded as a transition stage between asphaltum and asphaltite (see also this J., 1913, 646; 1914, 470). *Determination of the melting point of asphaltum*: In determining the dropping point of asphaltum with Ubbelohde's apparatus (this J., 1905, 941), concordant results can only be obtained when the lower opening has a diameter of exactly 3 mm. Barta's modification of the Krämer-Sarnow method of determining the softening point (this J., 1911, 1367) gives lower values than the Ubbelohde method, owing to the pressure of the mercury. Comparative determinations with ceresins showed that the m. pt. (Krämer-Sarnow) was as a rule almost as high as the first signs of fluidity in Ubbelohde's dropping method and the initial m. pt. in a capillary tube, whilst the dropping point was nearly the same as the stage of complete fusion in a capillary tube. For determining the m. pt. of asphaltums the Krämer-Sarnow method should be used for the incipient fusion, and the Ubbelohde method for complete fusion. The differences between the two points ranged from 15 to 20° C. in the case of nine typical samples of natural and oil asphaltums (see also this J., 1914, 470).—C. A. M.

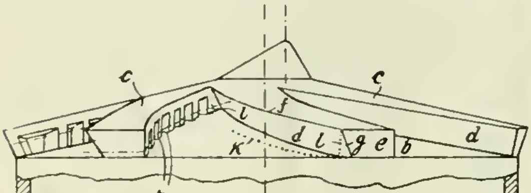
Patents.

Gas generators; Rotary grates for ——. K. Koller, Budapest, Hungary. Eng. Pat. 1692, Jan. 21, 1914. Under Int. Conv., Jan. 22, 1913.

A rotating conical grate, *a*, has curved cutting members, *c*, of which the forward face, *d*, is convex and is inclined at about 45°, so that the space, *f*, *g*, *k*, *l*, is free from vertical pressure and the cut slag in this space can move freely outwards as the grate rotates. The blast orifices are formed in the rear face of the cutting members, as shown at *p*. The grate may be used with a rotary slag pan having curved shearing blades as described in Eng. Pats. 7330 and 17,368 of 1911.—A. T. L.



Ammonia; Process and apparatus for increasing the yield of —— *in the manufacture of gas from solid fuels.* K. P. Sachs. Ger. Pat. 274,011, Dec. 13, 1912.

The gas is withdrawn from the interior of the bed of fuel through perforated tubes provided with a cooling device (cooling coil, water-jacket, or the like). Up to 90% of the total nitrogen of the fuel can be recovered as ammonia. —A. S.

Liquid fuel; Production of combustible gas or vapour [for internal combustion engines] from ——. F. G. L. Biddlecombe, Luton, Beds. Eng. Pat. 10.305, May 1, 1913.

Heavy hydrocarbon fuel, such as paraffin, together with a little air, is drawn by the suction of the engine through a spraying nozzle into a chamber in which partial combustion takes place, the ignition being at first effected by a sparking plug and afterwards maintained by the flame in the chamber. The spraying nozzle may be so formed that the air and oil receive a whirling motion. A further supply of air is admitted to the chamber through an automatic valve. The combustion is incomplete and the products, containing a large quantity of vaporised or gasified fuel, and are mixed with air for use in the engine. —A. T. L.

[Mineral] Oil; Methods of and apparatus for purifying ——. R. B. Ransford, London. From M. E. Shiner, Bayonne, N.J., U.S.A. Eng. Pat. 13,441, June 10, 1913.

The oil is passed successively upwards through three vessels, wherein it meets a descending current of warm or hot water, the water supply being regulated so as to bring the temperature of the oil to 60° F. (15·5° C.). The oil then flows upwards through a settling tank, and through an acid washer, a series of three vessels in which acid is removed by washing with water, a settling tank, an alkali washer, and, finally, through another settling tank. The acid and alkali washers are vertical cylindrical vessels in which the oil flows upwards and the acid or alkali downwards through a series of rotating perforated plates mounted on a vertical shaft. A series of fixed funnel-shaped partitions, arranged alternately with the perforated plates, directs the descending current towards the centres of the plates.—A. T. L.

Lubricants or the like; Manufacture of ——. F. C. Fresenius, Offenbach a/Main, Germany. Eng. Pat. 19,338, Aug. 26, 1913.

Fine pure soot (50% or more) is mixed with mineral or other lubricating oils. The soot is prepared by strongly heating lampblack in the absence of air, and then sifting it and separating the heavier particles by a current of air. —A. T. L.

Coal; Process and apparatus for agglomerating ——. H. Steven, Gilly, Belgium. Eng. Pat. 228, Jan. 5. 1914. Under Int. Conv., Jan. 20, 1913.

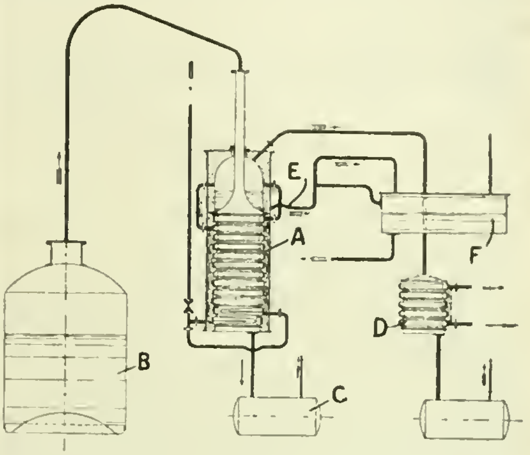
Conducting-filaments ; Process of preparing ——. H. D. Madden, Bloomfield, N.J., and W. G. Houskeeper, Philadelphia, Assignors to Westinghouse Lamp Co. U.S. Pat. 1,099,095, June 2, 1914. Date of appl., March 31, 1909.

See Fr. Pat. 414,257 of 1910 ; this J., 1910, 1195.—T. F. B.

III.—TAR AND TAR PRODUCTS.

Tar and petroleum distillation ; Economy of heat in ——. P. W. Uhlmann. Chem. Apparatur, 1914, 1, 177—179.



Apparatus is described for dehydrating tar or crude oil and distilling the lighter fractions by means of the hot vapours from the still, whereby smaller quantities of coal and of cooling water are required, tho saving of coal being about 2% of the weight of tar or oil distilled. The crude oil or tar circulates upwards in a tortuous path through hollow partitions in tho vessel, A, and is heated by the vapours from the still, B, which pass downwards through A, and are condensed, the middle, heavy and anthracene oils being collected in a tank, C. Owing to tho gradual heating of the tar or crude oil in A, there is very little frothing. The steam and light oil vapours pass from tho top of A to a condenser, D, and the dehydrated tar or oil, freed from its lighter constituents, is run off from the vessel, A, at E, and passed from the tank, F, to the still, B.—A. T. L.

Pitch cancer ; Note on the bases of gasworks coal-tar which are believed to be the predisposing cause of ——, *with special reference to their action on lymphocytes, together with a method for their inactivation. Part I. Auxetic action.* D. Norris. Biochem. J., 1914, 8, 253—260.

According to Ross and Cropper (see this J., 1913, 416) the predisposition to cancer caused by pitch is due to the presence therein of two classes of substances, namely auxetics (mostly amino-compounds), which induce cell-division in white blood cells, and kinetics (including most of the alkaloids) which excite amœboid movements in cells. Experiments by the author show that tho auxetics in coal-tar are bases present in the anthracene fraction (b. pt. 100°—200° C. at 16 mm.). The bases may be separated from the tar by shaking it for 1 hour with twice its volume of 5% hydrochloric acid, allowing to stand overnight, centrifuging, and precipitating the bases from the acid liquor with strong ammonia, care being taken not to add excess. Attempts were made to isolate the bases by fractional crystallisation of the picrates. The most insoluble picrate melted at 199°—201° C. and had the composition, $C_{22}H_{14}O_9N_6$. The free base separated therefrom possessed auxetic activity. Another picrate fraction melted at 161°—162° C., but the quantity was not sufficient for analysis. The auxetic activity of aqueous extracts of tar is rapidly lost on exposure to air and a simple method of rendering the tar inactive in regard to auxetic power consists in heating it to 160° C. and subjecting it to the action of a blast of air or ozonised air (see also Eng. Pat. 11,984 of 1913 ; following.) Another method for rendering the auxetics inactive, viz., treatment with formaldehyde (Robinson, Eng. Pats. 4159 and 10,156 of 1913 ; this J., 1914, 412), is being tried on a practical scale in a briquette works at Cardiff to ascertain whether the treatment is effective in preventing pitch cancer among the workmen.—A. S.

Bromination of benzene and its homologues. Catalytic action of manganese. L. Gay, F. Ducelliez and A. Raynaud. Comptes rend., 1914, **158**, 1804—1806.

Metallic manganese accelerates the action of bromine on benzene and toluene very considerably and is not itself changed in the process if the reagents are dry.—W. H. P.

Patents.

Tar, tar oils, or pitch; Method of and means for removing deleterious substances from ——. H. C. Ross, Chelsea. Eng. Pat. 11,984, May 22, 1913.

The "auxetics" present in tar, tar oils, or pitch are removed by bringing the substance into intimate contact and spraying it with hot water or hot dilute acid, projecting the mixture on to a plate or plates to effect further division and mixing, then agitating the mixture, and finally allowing it to separate and removing the aqueous liquid. In treating tar, about twice its volume of hot water (at 100° to 212° C.) may be used, whilst when using an acid solution (*e.g.*, 5% sulphuric or hydrochloric acid) half this amount may suffice. The auxetics may be removed or destroyed by passing air or oxygen (which may be ozonised) through the tar or tar product during distillation or at any other convenient stage of manufacture. An apparatus suitable for carrying out the above process is described.—T. F. B.

Arylides of 2.3-[hydr]oxynaphthoic acid and formaldehyde; Manufacture of condensation products from the ——. Chem. Fabr. Griesheim-Elektron, Frankfort, Germany. Eng. Pat. 3312, Feb. 7, 1914. Under Int. Conv., May 17, 1913.

Formaldehyde acts very readily on the arylides of 2.3-hydroxynaphthoic acid in alkaline solution, even at the ordinary temperature, forming products which can be separated from solution by precipitation with acid. The constitution of the new products has not been determined, but they differ from the arylides themselves in being less easily soluble (*e.g.*, in acetone) and they are decomposed by heat. They may be used as azo dyestuff components—T. F. B.

Nitro products from petroleum and tar; Manufacture of ——. A. S. Flexer, Vienna. U.S. Pat. 1,099,976, June 16, 1914. Date of appl., July 21, 1913.

See Fr. Pat. 460,281 of 1913; this J., 1914, 17.—T. F. B.

Arylamides of 2.3-[hydr-]oxynaphthoic acid; Process of making the ——. A. Zitscher, Offenbach, Assignor to Chem. Fabr. Griesheim-Elektron, Frankfort on Maine, Germany. U.S. Pat. 1,101,111, June 23, 1914. Date of appl., Nov. 14, 1913.

Method of dehydrating fats, oils, hydrocarbons, etc. Ger. Pat. 273,555. *See* XII.

IV.—COLOURING MATTERS AND DYES.

Lokao dyestuff. [*Chinese green.*] A. Rüdiger. Arch. Pharm., 1914, **252**, 165—186.

Lokao contains a blue dyestuff lokaonic acid, $C_{42}H_{46}O_{25}$, in combination with calcium and aluminium. The acid forms unstable ammonium salts and is readily hydrolysed by dilute hydrochloric acid to form rhamnose and a violet dyestuff, lokanic acid, $C_{36}H_{36}O_{21}$. Concentrated potassium hydroxide solution decomposes lokanic acid into phloroglucinol and delokanic acid, $C_{12}H_8O_5$. The latter is a black powder insoluble in water, but forming a cherry-red solution with alkalis. It is decomposed by nitric acid with the formation of oxalic acid and the methyl ether of nitrohydroxybenzoic acid. Lokao is possibly a derivative of flavone.—F. Shdn.

[*Preparation of anthraquinone, Aniline Black, Indulines, etc.*] *Magnesium chloride. II. Its effect on the oxidising action of chlorates and nitrates.* K. A. Hofmann, F. Quoos and O. Schneider. Ber., 1914, **47**, 1991—1999.

The oxidising action of chlorates, nitrates, and nitrites is promoted to a remarkable extent by the presence of large quantities of hydrated magnesium chloride, present in the mother-liquors produced in enormous quantities in the manufacture of potassium salts from carnallite. For example, whilst anhydrous nitrates and chlorates produce only small quantities of anthraquinone when heated with anthracene even at high temperatures, a yield of 18·9 grms. of nearly pure anthraquinone was obtained by heating 20 grms. of anthracene, 23 grms. of sodium nitrate, and 80 grms. of $MgCl_2,6H_2O$ in an open flask; formation of anthraquinone began at about 125° C., and when the temperature reached 145° C., 40 c.c. of water were added, and the temperature then raised gradually to 300° C. The anthraquinone formed an upper layer and was purified by mixing with 5 grms. of magnesia and subliming. A quantitative yield (8·3 grms.) of greenish Aniline Black was obtained by heating a solution of 10 grms. of aniline hydrochloride and 5 grms. of sodium chlorate in 35 c.c. of water with 20 grms. $MgCl_2,6H_2O$ for 2 hours at 90° C.; without magnesium chloride the yield was only 0·5 grm. Indulines and Paraphenylene Blue were obtained in a similar manner from a mixture of aniline and *p*-phenylenediamine hydrochloride. From a mixture of 9 grms. of dimethyl-*p*-phenylenediamine hydrochloride, 10 grms. of α-naphthol, 4 grms. of potassium chlorate, 40 grms. $MgCl_2,6H_2O$, and 10 c.c. of water, a product was obtained which with zinc dust and ammonia gave a vat dyeing indigo-blue shades similar to those obtained with commercial indophenol. A mixture of *p*-toluylenediamin hydrochloride, aniline, *o*-toluidine, potassium chlorate hydrated magnesium chloride, and water gave Safranin and other products insoluble in sodium carbonate solution In the production of induline from aniline, aniline hydrochloride, and aminoazobenzene, the previous preparatio of the last-named may be avoided. For example a coole mixture of 9 grms. of aniline, 32 grms. of aniline hydrochloride, 70 grms. $MgCl_2,6H_2O$, and 50 c.c. of water wa treated with a solution of 7·5 grms. of sodium nitrite i 25 c.c. of water, and after 3 hours at the ordinary temperature, was heated to 120° C. The product consisted chief of alcohol-soluble induline. Phenols and β-naphth can be converted into nitroso-compounds by treatmen in neutral or feebly alkaline solution with sodium nitrit in presence of a large quantity of hydrated magnesiu chloride or sulphate. A yield of oxalic acid correspondin to 7·5 grms. of calcium oxalate was obtained from 12 grm of beechwood sawdust, 80 grms. $MgCl_2,6H_2O$, 10 grms. magnesia, and 17 grms. of sodium chlorate. Oxalic ac was also obtained from molasses at 250°—300° C., considerable quantity of trimethylamine being first form at a lower temperature. The authors conclude from the experiments that the activating influence of magnesiu chloride is not due to hydrolytic dissociation, but probab to its great tendency to complex organic formation.—A.

Influence of artificial organic colouring matters on enzymic hydrolysis of proteins. Diaminovich a Guglialmelli. *See* XIXa.

Patents.

Colouring matters; Manufacture of fast light-proof — N. W. Turkin, Moscow. Eng. Pat. 5737, March 1913.

A colloidal solution of the colouring matter is formed i mass containing Turkey red oil and a salt of an alkali alkaline-earth metal by heating the mixture until solidifies on cooling. The use of basic aluminium acetate is advantageous, also the addition of naphthalene and certain oils and fats containing trimethylamine, cholesterol or triglycerides, these additions improving the fastness to light. All coal tar dyes are suitable for use in the process, and a variety of indifferent materials may be added to the mass. A special diluting varnish made by heating fish oil with naphtha and dissolving the product in naphtha, etc., is used for preparing paints and printing mixtures.—I. B.

Trisazo dyestuffs ; Manufacture of ——. R. B. Ransford, London. From L. Cassella und Co., Frankfort on Maine, Germany. Eng. Pat. 17,030, July 24, 1913.

This process relates to the manufacture of dyestuffs of the type, naphtholdisulphonic acid-N_2-P-N_2-naphthylaminesulphonic acid (1.6 or 1.7)-X, where P represents a p-phenylene or substituted *p*-phenylene nucleus and X a further diazotisable amine other than an aminonaphtholsulphonic acid. They may be obtained by combining a compound of the type, -N_2-P-N_2-naphtholdisulphonic acid with 1.6 or 1.7-naphthylaminesulphonic acid, diazotising, and combining with a diazotisable amine as mentioned above, or by combining a compound of the type, -N_2-P-N_2-Clève acid, with a naphtholdisulphonic acid, diazotising, and combining with an amine, or from a compound of the type, -N_2-P-N_2-Clève acid -NO_2 or -NH-acidyl by combining with a naphtholdisulphonic acid, reducing or saponifying, diazotising, and combining with a diazotisable amine. The dyestuffs obtained by this process can be diazotised on the fibre and developed with β-naphthol, producing blue shades fast to washing and light.—T. F. B.

Diazo salts in a solid form ; Method for producing ——. R. B. Ransford, London. From L. Cassella und Co., G. m. b. H., Frankfort on Maine, Germany. Eng. Pat. 23,945, Oct. 22, 1913.

The stability of the solid diazo compounds, obtained by diazotisation in concentrated sulphuric acid and converting the excess of acid into bisulphate, may be considerably increased by adding to the liquid, after diazotisation, magnesia or magnesium carbonate to neutralise the greater part of the acid. For example, 21 kilos. of *p*-nitraniline are mixed with 36·6 kilos. of a mixture of equal parts of nitrosulphuric and sulphuric acids ; when diazotisation is complete, 8 kilos. of magnesia and then 36 kilos. of powdered potassium or sodium sulphate are added. The mass becomes stiff after a short time, and can be ground to an almost colourless, very stable powder.—T. F. B.

Anthracene] dyestuffs ; Manufacture of ——. R. B. Ransford, London. From L. Cassella und Co. G. m. b. H., Frankfort-on-Maine, Germany. Eng. Pat. 1443, Jan. 19, 1914.

1-AMINO-2-METHYLANTHRAQUINONE is heated with sulphur to a high temperature in presence of an aromatic amine having at least two amino groups in the molecule. When p-phenylenediamine is the amine used, a product dyeing violet shades is obtained, whilst with benzidine a claret dyestuff is produced. The use of one mol. of the amine to two mols. of the anthraquinone derivative gives especially good results. Instead of aromatic amines, nitro or azo compounds which yield on reduction compounds having at least two amino groups may be used.—T. F. B.

Azo dyes ; Manufacture of ——. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 22,313, Oct. 3, 1913.

The diazo compounds of o-nitraniline or its homologues or derivatives are combined with acetoacetic-anilide-*p*-carboxylic acid. The products are soluble in water and are particularly suitable for preparing lakes, which are pure greenish-yellow in colour, and very fast to oil and to water. The acetoacetic-anilide-*p*-carboxylic acid may be obtained by heating an ester of *p*-aminobenzoic acid with acetoacetic ester and saponifying the resulting ester. —T. F. B.

Vat dyestuffs ; Manufacture of ——. O. Imray, London. From Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. Eng. Pat. 3682, Feb. 12, 1914. Addition to Eng. Pat. 19,599, Aug. 27, 1912.

THE condensation products of halogen-quinones and arylamines are treated with sulphur compounds other than those enumerated in Eng. Pats. 19,599 of 1912 and 22,528 of 1913 (see Fr. Pat. 447,592 and Additions thereto, this J., 1913, 226 ; 1914, 247). The following may be used for this purpose :—Hydrosulphites, anhydrides of thiocarbonic acid, thiosulphuric acid or thiosulphates, sulphur alone or in presence of a substance capable of combining with halogen or acid (other than sodium or other metallic sulphide or sulphydrate included in Eng. Pat. 19,599 of 1912), or a sulphur halide. A diluent may be used. Some of these substances give rise to products closely resembling those previously described, whilst in other cases different products are formed. For example, the dyestuffs obtained by the action of a thiosulphate or of sulphur in presence of a substance capable of binding halogen or acid, dye wool olive-grey, greyish-brown, greyish-blue, and brownish-black shades.—T. F. B.

Dyestuffs of the Quinoline Yellow series ; Manufacture of halogenated ——. O. Imray, London. From Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. Eng. Pat. 8577, April 4, 1914.

PHTHALIC acid is condensed with a *m*-halogen-quinaldine or a halogenated quinaldine or a homologue thereof, which contains a halogen or methyl group in the *o*-position to the nitrogen, and the substituted quinophthalones thus formed are sulphonated. The products are faster to light than Quinoline Yellow.—T. F. B.

Pigments ; New compound [3.3′-dinitro-4.4′-diaminobenzophenone] suitable for use in the manufacture of ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 8690 of 1914, date of appl., Sept. 5, 1913.

4.4′-DICHLOROBENZOPHENONE is nitrated and the product is heated for 10 hours at 150°—160° C. with alcoholic ammonia containing 10% NH_3 ; after crystallisation from *m*-cresol the product melts at 292° C., and is considered to be 3.3′dinitro-4.4′-diaminobenzophenone ; it differs materially from the product obtained by Consonno by nitrating diaminobenzophenone, which melts at 121° C. If 10% aqueous ammonia is used, the diamino compound is obtained mixed with 3.3′-diamino-4-chloro-4-aminobenzophenone.—T. F. B.

Azo dyestuffs for wool ; Manufacture of ——. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 14,700, June 25, 1913.

V.—FIBRES ; TEXTILES ; CELLULOSE ; PAPER.

Cellulose ; Action of cuprammonium hydroxide on ——. E. Connerade. Bull. Soc. Chim. Belg., 1914, **28**, 176—186.

A physico-chemical investigation of the action of cuprammonium hydroxide solution on cotton cellulose. From the results it is concluded that cuprammonium solutions made at low temperatures contain a relatively large amount of the colloidal cuprammonium hydroxide and that the solubility of cellulose is proportional to its concentration, the cupric hydroxide as such playing a secondary part in the reaction. The solution of the cellulose appears to be brought about by the fixation of increasing amounts of colloidal cuprammonium hydroxide and water up to a limit of equilibrium between the liquid and solid phases ; the strongly hydrated colloidal complex also fixes ammonia in proportion to its concentration, tending towards stabilisation of the solution. The coagulation of the complex in solution is reversible.—R. G. P.

Cellulose ; Action of concentrated sulphuric acid on ——. S. Tschumanow. Kolloid-Zeits., 1914, **14**. 321—322.

Strips of filter-paper weighing respectively (1) 0·083, (2) 0·1714, (3) 0·3296, (4) 0·654, (5) 1·264, and (6) 2·5913 grms. were each left in contact with 100 c.c. of sulphuric acid of sp. gr. 1·84. After 24 hours there resulted : (1) a clear olive green liquid, (2) a clear dark greenish brown liquid, (3) to (6) dark-coloured liquids ; after 3 days all the solutions were black. 50 c.c. of solution (6) was diluted with 2 litres of water, the precipitate washed free from sulphuric acid, and dried at 100°—112° C. ; it contained : C 62·10, H 5·00, O 32·90%. After remaining for 2½ years in a desiccator over sulphuric acid, solution (6) had set to a gelatinous mass. (See also Sabbatani, this J., 1914, 692.)—A. S.

Nitrocellulose ; Solubility of —— *in ethyl alcohol.* H. Schwarz. Caoutchouc et Guttapercha, 1914, **11**, 7964—7967, 8199—8200 and 8359—8360.

From published data and his own experimental results, the author shows that the solubility of various kinds of nitrocellulose is greatly influenced by the purity and mode of preparation of the nitrocellulose and the purity of the solvent. In particular, while the solubility in boiling absolute alcohol was high, it rapidly decreased when water was present, becoming practically zero for 88% alcohol. Similar results were obtained with cold alcohol. Commercial alcohol gave somewhat higher results probably owing to the impurities present. Experiments are also described showing the influence of the time of nitration of the cellulose. The solubility first rises with increased time of nitration, then oscillates and finally falls.—H. E. P.

Paper pulp in the United States ; New sources of supply of raw material for ——. V. E. Nunez. Papierfab., 1914, **12**, Fest-heft, 41—44.

In 10 years, from 1900 to 1909, the consumption of pulpwood in the United States increased by 100%, the increase in home-grown spruce being 35% and in imported spruce 162%. At present only one-third of the pulp wood consumed in the United States is home-grown and the present supplies in that country will probably be exhausted in 30 years. On the other hand, much progress has been made in the utilisation of other species of wood, which have hitherto been considered inferior for pulp making. Balsam fir has been found to be a fairly satisfactory substitute for spruce in the manufacture of mechanical pulp for news-paper, whilst jack-pine and hemlock yield lower grade mechanical pulp suitable for cheap qualities. Tests are being made with several other varieties of wood available in large quantities in the Western States. The inferior woods are preferably ground in admixture with spruce ; fir wood tends to give a free coarse pulp of inferior colour to that of spruce ; the yield per cord is less owing to the lower density of the wood. In the South, progress has been made in the utilisation of lumber waste ; chiefly from long-leaf pine, for the manufacture of a Kraft-cellulose by the sulphate process. It is estimated that sufficient of this waste is available for the production of 10,000 tons of paper per day. There is also a large supply of stumps of black gum wood (*Nyssa sylvatica*) which yields a short-fibred pulp of the poplar class. Large amounts of Douglas fir are still untouched on the Pacific slope in the North. Of the minor sources of supply of paper-making material, sugar-cane refuse, previously shredded and largely freed from "pith" by the Simmons process is considered the most promising. Fibrous waste from the sisal plantations of Yucatan is also available in substantial quantities and yields paper pulp of excellent quality. Cottonseed hull fibres and flax straw are capable of development in their respective classes. Corn (maize) stalks, saw grass, cotton stalks and many other plants are under investigation but do not promise so well as the materials previously mentioned.—J. F. B.

Sulphite pulp ; Manufacture of ——. A. D. J. Kuhn. Papierfab., 1914, **11**, Fest-heft, 53—60.

The processes and apparatus employed for the treatment and purification of sulphite pulp after it is discharged from the digesters are described, with diagrams. Fou typical modern systems are illustrated. When the contents of the digester are discharged by blowing out unde pressure, the pulp should fall immediately into a ches containing hot water in order to avoid coagulation o resin ; it is washed repeatedly with hot water in th same chest, which is provided with a perforated bottom In the best system, the pulp is not subjected at this stag to the action of a centrifugal pump, which would tend t break up knots, etc., forming splinters ; it is preferabl diluted largely with water and run from the chest over channel containing traps for the coarse underboiled lump and through drum-screens which separate knots an splinters. In this way the hardest portions are remove before the pulp receives any mechanical treatment an the stuff which passes on to the potchers or "separators is sufficiently soft to break down completely with moderat agitation. The subsequent operations comprise screenin through a drum of finer mesh, passage over sand-tabl in a highly dilute form, removal of a portion of the wate straining through fine strainers and running off on presse-pâte or equivalent machine. The sand-tables mu not be so wide as to retard the velocity of the stuff, an bends, which cause eddies, must be avoided. The cleaning of the tables is facilitated by slanting the botto laterally. The cross-bars of the traps may be mount on hinges and swung up for cleaning the table. Fi strainers of all types are employed ; the slits should be narrow as possible and their capacity not over-taxe continuous, regular work gives better results than intmittent operation. The chemical purification is co trolled by determinations of ash and acidity.—J. F. B.

Soda cellulose mills ; Soda recovery plant in ——. Schröder. Chem. App., 1914, **1**, 161—168.

A description of the process and plant employed at German esparto mill, producing 18 tons of cellulose 24 hours from 40 tons of grass, the consumption of so (as Na_2O) being 4·2 tons. The amount of waste (sp. gr. 1·051) from the digesters was 138,000 litres day, giving, when mixed with wash waters, 220,000 lit of feed lye of sp. gr. 1·032 for the evaporators. The stro waste lye from the digesters gave, per 100 c.c., 15 grms. evaporation residue, having the composition : wat, 20·18 ; ash, 25·17, combustible matter, 54·65%.

iluted feed-lye contained 5·06% of combustible matter y weight. Calorimetric determinations showed a value f 2451 Cals. for the evaporation residue, the water being alculated as vapour; this is equivalent to a calorific alue of 4500 Cals. for the combustible matter present. he quantity of combustible matter in the lyes worked ut at 11,455 kilos. per day, equal to 7·98 kilos. per min. he lyes to be evaporated were fed, at a temperature of 0° C., at the rate of 157·75 kilos. of dilute feed-lye per in., to a triple-effect vacuum evaporator and the partally concentrated product was passed forward to a rotary late-evaporator, where it came in contact with the ombustion gases from the incinerating furnace. The late-evaporator consisted of a number of metal plates discs partially immersed in the lye and partially posed to the furnace gases; thus a film of the lye is icked up, evaporated and renewed as the discs revolve. he furnace consisted of two parts: a rotary kiln in hich the evaporation was continued to the flaming oint and a vertical finishing furnace in which the comistion of the coked ash was completed. The draught the latter was so regulated as to burn practically all the rbon without fusing the ash. The total heat developed the furnace was calculated at 43,092 Cals. per min., which, assuming losses of 40%, 25,855 were available r evaporative work in the rotary apparatus. At the te of 580 Cals. required to heat up to boiling point and aporate 1 kilo. of water from the thickened lye delivered om the vacuum pan, it is calculated that 44·58 kilos. of ater per min. were evaporated at the expense of the mbustible matters of the lyes. Adding to this, 13·69 los. per min., as the weight of the residue of evaporation, 7·75—58·27=99·48 kilos. per min. represents the antity of water to be evaporated in the triple-effect cuum plant. This evaporation, including heating up e feed-lye, was effected by a consumption of 20,613 Cals. r min., supplied in the form of exhaust steam at 106° C., d the plant yielded 136·17 kilos. of hot distilled water r min. having a heat value above atmospheric temrature of 8119 Cals. The recovery of soda was at the te of 90%, equal to 6840 kilos. of calcined ash per 24 urs at a total cost, including all charges, of M. 305 out £15).—J. F. B.

per pulp; Terpene by-products in the manufacture of ——. A. Luttringer. Papierfab., 1914, **12**, Fest-heft, 64—67.

E recovery of oil of turpentine and resin as by-products the manufacture of wood pulp by alkaline digestion is ly profitable with timber rich in resin. When chips wood of the ordinary size employed in pulp manufacture steamed, the recovery of oil of turpentine is far from nplete. In the ordinary digestion process pine wood lds about 5 kilos. of crude oil of turpentine per 1000 os. of wood. When this is obtained by the sulphate cess of digestion it is contaminated with dimethyl phide and has a very unpleasant odour. The methyl phide disappears on exposure to the air but oil of pentine is also lost; purification by distillation or by atment with 50% sulphuric acid does not appear to satisfactory in all cases. Stirring in sunlight with the lition of potassium chloride, also treatment with gaseous rogen oxides have been proposed. Dimethyl sulphide, en oxidised by nitric acid, yields a derivative of high ling point, soluble in water and a solvent of nitrolulose. The non-volatile resinous matter remaining in lyes separates out as an oil at a certain stage in the centration of the lyes; it is a commercial article under name of "liquid resin." The method of extracting resins from the wood by volatile solvents before estion does not appear to be profitable. A summary the various patents for extracting the resin by steam lkaline solvents, with a view to combining the recovery resin products and paper-pulp in one operation, is en. One of the most successful processes, operated France, consists in collecting the volatile oils at an ly stage of the digestion process and then subjecting evaporated waste lye, containing the fixed resin, to tructive distillation in closed retorts. It is necessary, vever, to treat wood exceptionally rich in resin.
—J. F. B.

Paper; The compression and density of raw materials for the manufacture of ——. C. Beadle and H. P. Stevens. Chem. News, 1914, **109**, 302—304.

The compression of fibrous raw materials for shipment is limited by three factors: cost of compression, effect of the compression on the subsequent manipulation of the material and the limit of "deadweight." Deadweight corresponds to a density of 56 lb. per cb. ft.—40 cb. ft. per ton, beyond which there is no object in reducing bulk for sea-transport. A very high compression would be detrimental in the case of esparto, since it would break down the structure, creating difficulties in opening out and cleaning the grass. In the case of cottonseed hull fibre, a high compression would have no ill-effect. Esparto bales bulk at the rate of 120 cb. ft. per ton from ordinary presses and 90 cb. ft. from hydraulic presses. Moist mechanical wood pulp averages 40 cb. ft., equivalent to 80 cb. ft. on the dry weight. The highest compression for air-dry sulphite pulp is 50 cb. ft.; with ordinary pressure 65 cb. ft. per ton. Soda pulp is more bulky, showing 80 cb. ft. for kraft pulp. All the wood pulps show fairly wide variations corresponding to variations in the quality of the fibres. *Hedychium coronarium* ranges from 90 cb. ft. for a continuous light baling press down to 33 cb. ft. for the heaviest hydraulic packing. The best way is to pack by the light continuous press as a preliminary operation and then to compress two bales into one by the heavy hydraulic press. When a bulky material has to be compressed with moderate pressure, a higher dry weight per cb. ft. can be obtained by pressing in the moist state, because the fibres are more yielding than when dry. When heavier pressures are employed, however, the moisture in the material maintains it in a swollen condition and causes it to resist extreme compression. With heavy pressing the densest bales are obtained from air-dry material.—J. F. B.

Paper-testing. Strength, bulk and handle. J. F. Briggs. Papierfab., 1914, **12**, Fest-heft, 25—29.

The term "breaking-length" expresses the conception of "specific strength" or strength-units per unit weight of paper. Applying the same principle to the bursting strain test, which is more usually employed in trade circles in England and America, the author proposes the ratio, bursting strain in lb.: demy weight in lb., as an expression of specific strength of the same order as the German breaking length. Similarly, "bulk" may be regarded as specific thickness, *i.e.*, thickness per unit weight of paper and is proportional to specific volume. It is proposed to record "bulk" in terms of the ratio, thickness of 4 plies in 1/1000 of an inch: demy weight in lb. It is argued that the commercial conception of "handle," originally a purely subjective impression, might be recorded numerically as an additive combination of the two factors specific strength and specific thickness, In judging writing papers and fine printings, a third factor comes in, *viz.*: "smartness" of appearance, which however, must remain subjective. Strength, bulk and "smartness" are the primary factors which determine the quality of fine papers and indicate the quality of the materials and the amount of technical skill employed in the manufacture. To a certain extent these factors are mutually inimical and the values obtained are the result of a compromise. In order to obtain the desired degree of "smartness" with papers of heavy substance it is frequently necessary to sacrifice one or both of the factors which combine to create the impression of "handle."—J. F. B.

Balsam fir as a pulp wood. Board of Trade J., June 11, 1914. [T.R.]

Balsam fir, a tree which was considered of little value a few years ago, is now in demand for pulp wood on account of the expansion of the pulp industry and the consequent rise in the price of spruce. Balsam has also begun to take the place of spruce for rough lumber, laths, etc. The chief objection to the use of large amounts of balsam fir in mechanical pulp is that the "pitch" in the wood injures the belts and cylinder faces upon which the pulp is rolled out: this, however, is probably due to grinding balsam under conditions adapted to spruce. The acids used in the manufacture of chemical pulp dissolve the pitch and any amount of balsam may be used, though it is said that too much balsam in the pulp yields a paper lacking in strength. The balsam fir grows in northern New York and Maine, in many parts of New Hampshire and Vermont, and in the swamps of Northern Michigan, Northern Wisconsin and Minnesota. It readily re-afforests cut-over areas, and quickly attains a size suitable for pulp wood.

Patents.

Antiseptic treatment of woollen cloth. D. Humphreys, Stroud. Eng. Pat. 13,408, June 10, 1913.

The cloth after being well washed is treated with a solution of about 1% of phenol "or other coal tar derivative" at 100° to 120° F. (38°—49° C.), squeezed between heavy rollers, dried at a gentle heat and then sprayed with thymol. —J. B.

Silk; Manufacture of ——. E. Graeger and A. Kemmler, Berlin. Eng. Pat. 2213, Jan. 27, 1914. Under Int. Conv., Jan. 28, 1913.

Raw silk, silk waste and cocoons are prepared for spinning into floss "schappe" by treatment first with a hot (60°—70° C.), feebly alkaline solution (*e.g.*, 0·25—0·5% sodium carbonate or 1% borax solution) and then with a solution of tryptic ferments, such as pancreatic preparations or a solution of papayotin, in presence of ammonium salts (0·5—1% NH_4Cl) and 1—3% of a neutral electrolyte such as sodium chloride.—J. F. B.

Flax and jute waste; Process for converting —— *into soft, curled, woolly fibres.* A. Seidel and J. Geisberger. Ger. Pat. 273,881, Dec. 20, 1912.

Flax or jute waste is digested under pressure for 3—4 hours in a lye consisting of urine, sodium carbonate, Turkey red oil soap, and water.—A. S.

Plastic composition [from cellulose esters] and process for making the same. W. A. Beatty, New York. Eng. Pat. 18,499, June 19, 1913.

A cellulose ester (nitrate or acetate) is incorporated with camphor and a condensation product of a ketone and a phenol (*e.g.*, dihydroxydiphenyldimethylmethane, obtained from acetone and phenol) with or without the use of other solid solvents such as camphor substitutes. (See also Eng. Pat. 18,822 of 1912; this J., 1913, 907.)—J. B.

Acetylcelluloses; Manufacture of —— *insoluble in acetic acid and chloroform.* Knoll und Co. Ger. Pat. 273,706, April 29, 1911.

Acetylcelluloses soluble in acetic acid and chloroform are left in contact with suitable catalysers, under such conditions that hydrolysis by water is avoided, until they become insoluble. Other substances may be added to the acetylcellulose before the treatment. For example, a solution of acetylcellulose in glacial acetic acid is treated with sulphuric acid, sulpho-acetic acid, zinc chloride, or the like, until a solid product, insoluble in chloroform and acetic acid, is produced. Or, solid acetylcellulose, in a suitably subdivided form, may be left in contact with benzene, a little sulpho-acetic acid and a solvent for the latter, such as acetic anhydride or acid. The new acetylcelluloses are soluble in formic acid, hydroxy-acids and their esters (*e.g.*, tartaric acid esters), acid derivatives of hydroxy-acids and their esters (*e.g.*, diacetyltartaric acid esters), acid derivatives of glycerol (acetins and chlorhydrins), nitromethane, and acetylenetetrachloride. They can be used for the preparation of artificial threads, films, celluloid, etc.—A. S.

Cellulose or substances containing cellulose; Preparation of solutions of —— *in concentrated hydrochloric acid, capable of being precipitated by water, alcohol, or saline solutions.* R. Willstätter. Ger. Pat. 273,800, May 25, 1913.

Hydrochloric acid of a higher concentration than 30% is used for dissolving cellulose (see also this J., 1913, 822). The solutions may be used in the production of artificial silk, films, etc.—A. S.

Cellulose: Installation for the manufacture of —— *by the indirect boiling process.* E. Morterud. Ger. Pat. 273,860, Aug. 13, 1913.

A central heating installation is used, from which the requisite quantity of heat for effecting the digestion is supplied to each of a number of digestors in turn.—A. S.

Nitrocellulose solutions; Method of spinning —— *for the production of threads, artificial horsehair, films, or the like.* E. Berl and M. Isler. Ger. Pat. 273,936, June 17, 1913.

Threads, films, or the like of collodion, prepared in the usual way from nitrocellulose containing 20—30% H_2O, are coagulated by aqueous alcohol of 25—50% (by vol.) concentration, at a temperature not exceeding the boiling point of ether.—A. S.

Acidylcelluloses; Manufacture of objects [threads] of ——. Knoll und Co. Ger. Pat. 274,260, July 18, 1912.

Solutions of acidylcellulose are precipitated by con centrated saline solutions. For example, a solution o acetylcellulose in glacial acetic acid is squirted into concentrated solution of sodium acetate.—A. S.

Bleaching ligno-cellulose and pecto-cellulose; Processes fo ——. A. R. de Vains and J. F. T. Peterson, Pari Eng. Pat. 19,099, Aug. 22, 1913. Under Int. Conv. Aug. 28, 1912.

See Fr. Pat. 449,497 of 1912; this J., 1913, 482.—T. F.

Binding and impregnating materials made from was sulphite lye. E. Pollacsek, San Bartolomeo, Ital Eng. Pat. 20,460, Sept. 10, 1913.

See Fr. Pat. 462,429 of 1913; this J., 1914, 248.—T. F.

Cuprammonium solutions; Process of producing —— B. Borzykowski, Charlottenburg, Germany. U.S. Pa 1,100,518, June 16, 1914. Date of appl., Nov. 18, 191

See Eng. Pat. 24,996 of 1912; this J., 1913, 283.—T. F.

Cellulose from raw vegetable materials containing cellul fibres; Manufacture of ——. L. Brech and Tyborowski, Warsaw, Russia. U.S. Pat. 1,100,51 June 16, 1914. Date of appl., April 17, 1911.

See Eng. Pat. 5552 of 1911; this J., 1912, 329.—T. F.

Flexible and waterproof material from paper sheets; Ma facture of ——. G. Magnasco, Genoa, Italy. U.S. P. 1,101,029, June 23, 1914. Date of appl., Aug. 14, 19

See Eng. Pat. 18,836 of 1913; this J., 1914, 640.—T. F.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Sorption [of acids by wool]; Kinetics of ——. G. Georgievics and A. Dietl. Z. physik. Chem., 1914, 669—691.

Acids are taken up more rapidly by wool the more centrated the solution, and the influence of concentrat on the velocity of absorption varies for different acid the same way as the quantity *x* (see this J., 1914, 251) be greatest in the case of the mineral acids where *x* ha large value, and least in the case of the monobasic fa acids. For gases, which are taken up by charcoal a velocity practically independent of pressure, *x* is unity the process is pure diffusion. These data support the Georgievics' theory of sorption (*loc. cit.*) as a combinat of diffusion (solution) and adsorption, the former dominating where *x* is low, the latter when it is h In the same group of acids the coefficients connec ırption with concentration follow the same order as those ›nnecting diffusion with concentration, this arrangement ang particularly marked in the case of the fatty acids. he temperature-coefficient for the sorption velocity of etic and of hydrochloric acids is about 1·5, indicating gain that the process is one in which solution rather than emical action prevails, although the coefficient is stinctly higher than those usually found for rates of ffusion. On diluting an acid solution which is in uilibrium with wool, the new equilibrium point is tained almost instantaneously with acetic, oxalic, drochloric and sulphuric acids. The widely expressed inion that adsorption (or sorption) itself is a very rapid ocess is erroneous. The velocity varies from case to se, and in some instances equilibrium is only attained ter weeks of contact.—W. H. P.

lk ; The weighting of —— with substitutes for tin. E. Stern. Z. angew. Chem., 1914, 27, 357—358.

ıe earths of monazite sand, as well as titanium and conium compounds, have been studied with a view their use in weighting silk, and it is concluded that, ilst these compounds could not be used successfully by emselves as substitutes for tin salt, yet when used in njunction with tin, satisfactory results could be obtained. ıe metallic compounds are not considered to be ideal bstances for weighting ; it is suggested that substances alogous in constitution to silk fibroin would be preferle.—T. F. B.

yestuff and fibre ; Labile compounds of —— and their application in dyeing. M. von Iljinsky. Z. angew. Chem., 1914, 27, 356—357.

ıst dyeings can be produced with certain insoluble estuffs by immersing the fibre in an aqueous suspension the dyestuff. For example, cotton is dyed in a few nutes at the ordinary temperature by immersion in a th of acidified water containing 2% of Indanthrene arlet G. in suspension ; when gum or other colloid is ded to the bath, only feeble dyeings are produced, and ese are not fast to water. The process may be applied the dyeing of artificial silk, and is also valuable for use th dyestuffs which do not readily give level shades. nilar adsorption compounds of dye and fibre, termed abile lakes," are formed when the fibre is immersed in an ueous suspension of a mordant dyestuff in presence of a rdant ; the mordant dyestuff can also be applied in is way to fibres already dyed with vat dyestuffs. illiant Alizarin Red lakes are obtained by this method mercerised goods. The insoluble metallic compounds leuco-vat dyestuffs can be applied in a similar manner. m aqueous suspensions, giving dyeings which are t to soaping and rubbing. The fibre may be introced into a bath containing the unreduced dyestuff, netallic (*e.g.*, magnesium) hydroxide, and hydrosulphite, the leuco compound may be prepared first and the tallic salt may be precipitated and formed into a pension.—T. F. B.

Patents.

eing machine ; Piece ——. H. Cochrane, jun., Paisley. Eng. Pat. 13,689, June 13, 1913.

ᴇ machine is provided with two receivers, one on each e of the dye-box, and is equipped with winches and table driving gear, whereby the cloth is carried from receiver to the dye-box and from the latter to the ıer receiver, and *vice versa*, the operation being continued til the required shade is obtained, somewhat after the nner of the dye-jig.—J. B.

iline Black by oxidation in the air ; Dyeing fabrics and ibres with ——. A. E. Vergé, Vincennes, France. Eng. Pat. 18,246, Aug. 11, 1913. Addition to Eng. Pat. 15,668 of July 7, 1913 (this J., 1914, 418).

ᴇ bath is made up of 45 grms. of aniline, 3 grms. of henylenediamine, 35 grms. of hydrochloric acid of Bé. (sp. gr. 1·152), 5 grms. of 90% formic acid, about 12 grms. of copper salts comprising 0—9 grm. of sulphate and 12—3 grms. of acetate, 1—2 grms. of sodium metabisulphite and water to make up 1 litre. An ungreenable black is said to result by leaving the pieces to oxidise in the air for 12 to 24 hours. If necessary the pieces are "finished" by passing through a solution of aniline oil in water, preferably after chroming. (Reference is directed to Eng. Pat. 16,189 of 1907 ; this J., 1908, 851.) —J. B.

Printing ; Colour ——. N. W. Turkin, Moscow. Eng. Pat. 23,129, March 7, 1913.

Colour printing plates are coated with the preparation described in Eng. Pat. 5737 of 1913 (see page 742), or the blocks may be built up of bars consisting of the said preparation. For printing the plates are moistened with a liquid capable of dissolving the composition.—J. B.

Finishing, filling, loading and dressing textile goods. L. Lilienfeld, Vienna. Eng. Pat. 7317, March 23, 1914. Under Int. Conv., April 8, 1913. Addition to Eng. Pat. 25,215 of 1911, dated Nov. 12, 1910. (See this J., 1912, 813, 383.)

The goods are treated with a viscose solution having a content of alkali hydroxide less than, but at least sixtenths of its content of cellulose or hydrocellulose.—J. B.

Starch ; Process for utilising used —— in laundries. M. Brauer. Ger. Pat. 273,311, Aug. 2, 1913. Addition to Ger. Pat. 262,501.

To avoid the use of large settling vessels as described in the chief patent, the waste water holding starch in suspension is introduced, together with clean water, through pipes disposed side by side, into a rapidly rotating centrifuge. —A. S.

Ice colours [on cotton] ; Process of producing ——. A. Winther, A. L. Laska, A. Zitscher, F. Kunert, and E. Acker, Offenbach-on-Maine. Assignors to Chem. Fabr. Griesheim-Elektron, Frankfort-on-Maine, Germany. U.S. Pat. 1,099,108, June 2, 1914. Date of appl., Oct. 16, 1913.

See Eng. Pat. 17,279 of 1913 ; this J., 1914, 73.—T. F. B.

Dyeing process. J. A. Dominguez, Buenos Aires. U.S. Pat. 1,099,240, June 9, 1914. Date of appl., April 27, 1912.

See Addition of Dec. 13, 1911, to Fr. Pat. 437,020 of 1911 ; this J., 1912, 637.—T. F. B.

Textile fibres ; Apparatus for treating —— with liquids and gases. J., T., and E. Brandwood, Bury. U.S. Pat. 1,101,248, June 23, 1914. Date of appl., July 31, 1913.

See Eng. Pat. 5280 of 1913 ; this J., 1914, 133.—T. F. B.

Reserve effects on textile-fibre ; Production of ——. E. Bentz, Manchester, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 1,098,145, May 26, 1914. Date of appl., May 20, 1911.

See Eng. Pat. 16,389 of 1910 ; this J., 1911, 889.—T. F. B.

Cotton yarns and fabrics ; The finishing of ——. L. Hermsdorf and B. Teufer, Chemnitz, Saxony. Eng. Pat. 21,940, Sept. 29, 1913. Under Int. Conv., June 20, 1913.

See Fr. Pat. 463,073 of 1913 ; this J., 1914, 248.—T. F. B.

Coating flexible objects of organic origin with metal. R. Rafn and G. E. Schmidmer, Nuremberg, Germany. U.S. Pat. 1,099,934, June 16, 1914. Date of appl., Oct. 16, 1912.

See Eng. Pat. 23,959 of 1912 ; this J., 1913, 654.—T. F. B.

VII.—ACIDS ; ALKALIS ; SALTS ; NON-METALLIC ELEMENTS.

Selenious acid in sulphuric acid ; Detection of minute quantities of ——. E. Schmidt. Arch. Pharm., 1914, **252**, 161—165.

A few mgrms. of codeine phosphate are dissolved in 10 c.c. of the sulphuric acid, when a distinct green coloration appears changing to deep blue-green in about 15 mins. if selenious acid be present. The colour can be observed with 1 part of selenious acid in 1,000,000 parts of sulphuric acid.—F. Shdn.

Nitrogen in Norwegian saltpetre [*calcium nitrate*] *; Determination of* ——. N. Busvold. Chem.-Zeit., 1914, **38**, 799—800.

Lunge's nitrometer method gives results accurate to within about +0·13% N, but it is advisable to use an aqueous solution of phosphoric acid instead of water for the dilution, so as to prevent the precipitation of calcium sulphate and dissolve basic mercury sulphate. For greater accuracy Treadwell and Wegelin's alkaline reduction method (Diss., Zürich, 1907) may be used, the reduction flask being connected with the reflux condenser by means of a long tube inclined upwards at an angle of 120°. In this flask are placed 8 grms. of powdered Devarda's alloy, 5 c.c. of alcohol, 50 c.c. of a solution of the saltpetre (25 grms. in 500 c.c.) 50 c.c. of water, and 50 c.c. of sodium hydroxide solution (sp. gr. 1·3). About 20 mins. after the evolution of hydrogen has stopped, the contents of the flask are distilled to about 50 c.c., the distillate being received in standard acid, and the apparatus finally swept out by a current of air. Parallel results should not differ by more than 0·05% N.—C. A. M.

Ammonia, hydrocyanic acid, and cyanogen ; Catalytic combustion of —— *to nitric oxide.* W. Moldenhauer and O. Wehrheim. Z. angew. Chem., 1914, **27**, 334.

Nitrogen combined with carbon (in cyanogen compounds) can be converted into nitric oxide by catalytic combustion, the carbon being at the same time oxidised to the dioxide. Better yields of nitric oxide are obtained by combustion of cyanogen-nitrogen than from ammonia-nitrogen, whilst in the former case the condition of the catalyst and the time of contact of the cyanogen compound with it are not of so much importance as in the combustion of ammonia. The fact that good yields of nitric oxide can be obtained from cyanogen under conditions in which ammonia would be converted only into free nitrogen, indicates that the sensitiveness of the combustion of ammonia is not so much due to the decomposition of nascent nitric oxide as to the direct formation of free nitrogen.—T. F. B.

Bromides ; Detection of ——, *in presence of thiocyanates and ferrocyanides.* I. Guareschi. Z. anal. Chem., 1914, **53**, 490—495.

The reaction previously described for the detection of bromide (this J., 1913, 942) may also be used in detecting traces of bromide in presence of thiocyanate or ferrocyanide ; in these cases the solid or its very concentrated solution is heated with excess of 50% chromic acid solution to gentle boiling. The test is still effective if both chloride and iodide are also present. Bromine was in this way readily detected in mixtures of 0·5 grm. of silver thiocyanate with 0·001 grm. of silver bromide and 0·5 grm. of silver ferrocyanide with 0·005 grm. of silver bromide. Traces of bromine were also recognised by the same method in Prussian blue and ultramarine. It is suggested that in the case of thiocyanates bromocyanogen is first produced and then decomposed in the following manner :

$$6CNBr+12H_2O=6CO_2+6NH_3+6HBr\ ;$$
$$6HBr+2H_2CrO_4=Cr_2O_3+5H_2O+3Br_2.$$

—J. R.

Borates. The system : $BaO—B_2O_3—H_2O$ at 30° C. U. Sborgi. Atti R. Accad. dei Lincei, Roma, 1914, **23**, I., 530—534, 717—721, 854—857.

By the interaction of barium hydroxide and boric acid in aqueous solution under varying conditions, products were obtained of the composition, $BaO,B_2O_3,4H_2O$; $2BaO,3B_2O_3,6H_2O$; and $BaO,3B_2O_3,7H_2O$ respectively and also one in which the ratio $BaO : B_2O_3$ was between 1 : 3 and 2 : 3. These products, together with baryta and boric acid were used in a study of the conditions of equilibrium of the system, BaO-B_2O_3-H_2O, at 30° C. in the same manner as was described previously (this J., 1913, 230, 655). The experimental results are tabulated and indicate that at 30° C. the only compounds formed are the triborate ($BaO,3B_2O_3,xH_2O$) and the metaborate (BaO,B_2O_3,xH_2O). —A. S.

Lead in bismuth subnitrate ; Detection of ——. G. Guérin. J. Pharm. Chim., 1914, **10**, 22—23.

Certain commercial samples of bismuth subnitrate when tested for lead by the method previously described (this J., 1913, 1107) were partially soluble in boiling 5% ammonium nitrate solution, and the filtrate then gave a yellow precipitate with potassium chromate in the absence of lead. Lead chromate is soluble in sodium hydroxide solution, and is reprecipitated by acetic acid, whereas a mixture of bismuth and lead chromates is partially soluble in the alkali and on adding a slight excess of acetic acid to the filtrate only the lead chromate is immediately re-precipitated.—C. A. M.

Iron and chromium nitrides. W. Moldenhauer and F. Groobe. Z. angew. Chem., 1914, **27**, 334.

Finely divided iron, prepared by reduction of the oxide, combines chemically with small quantities of nitroger on heating in presence of the gas for a short time. Th amount of nitrogen combined between 450° and 850° C is about 0·25%. When the heating is prolonged a temperatures above 600°, the amount combined is mucl smaller. It is suggested that a saturated solid solutio of nitride in iron is formed, and that the dissociation tension of the dissolved nitride increases with the time as is known to be the case with chromium nitride. chromium nitride, Cr_2N, has been obtained, togethe with CrN, by the action of nitrogen on chromium. It i soluble in dilute hydrochloric and sulphuric acids (CrN i only decomposed by concentrated sulphuric acid), and i converted into CrN by heating strongly.—T. F. B.

Tungsten ; Preparation and properties of some derivati of pentavalent ——. A. Fischer. Z. angew. Chem 1914, **27**, 336.

The reduction of tungsten hexachloride in ethyl alc holic solution by means of aluminium, in presence of dehydrating agent, results in the production of a hig yield of the green compound of pentavalent tungste $WCl_2(OC_2H_5)_3$; it is decomposed by water, and possess strong reducing power, *e.g.*, for indigo solution. analogous compound, also with reducing properties, h been prepared by replacing the ethyl alcohol by meth alcohol.—T. F. B.

Explosive substance containing arsenic. W. J. Müll Z. angew. Chem., 1914, **27**, 338.

A black substance which exploded on contact with flame or when rubbed with a hard body, was fou deposited on the iron in a lead-lined wrought-iron ves which had contained strongly arsenious, 35% sulphu acid, the lead having been corroded in places. It c tained iron, lead, and arsenic ; the arsenic content increased to 43% on washing with hydrochloric ac —T. F. B.

Radium emanation ; Reduction of carbon monoxide hydrogen under the influence of ——. O. Scheu Comptes rend., 1914, **158**, 1887—1889.

When purified radium emanation is introduced int mixture of carbon monoxide and hydrogen at the ordin temperaturo reduction takes place slowly with the production of water vapour, mothano and a small proportion of other hydrocarbons.—F. Sodn.

Sulphur chloride ; Examination of ——. F. Frank and E. Marckwald. Gummi-Zeit., 1914, **28**, 1580—1581.

The authors suggest that good samples of sulphur chloride should possess a sp. gr. (15° C.) of 1·680 to 1·690 (pure 1·681). When 105 c.c. are distilled, using a standard flask and condenser (of which minute details are given), 95 c.c. should distil within 4°, the first 5 c.c. being rejected. The sample should contain at least 98·8% S_2Cl_2 calculated on the basis of chlorine content determined by the following new method :—10—15 c.c. of nitric acid (sp. gr. 1·5) (containing sufficient silver nitrate for the reaction) are introduced into a small pressure flask of 100 c.c. capacity, having a stopper ground in and secured by a lever. 0·2 to 0·5 grm. of the sample are weighed in a small weighing bottle which is then dropped into the flask. This is shaken till all the sulphur chloride has disappeared, warmed for 20—30 mins. on the waterbath, cooled and opened. The precipitate and glass are collected by means of water, the precipitate dissolved by ammonia, reprecipitated and weighed in a Gooch crucible. This process gives good results, higher than those obtained by the old method.—H. E. P.

Dicyandiamide ; Technical methods of obtaining —— from calcium cyanamide from the standpoint of chemical kinetics. G. Grube and P. Nitsche. Z. angew Chem., 1914, **27**, 368—378.

The method described in a previous paper (this J., 1914, 75) has been tested kinetically, and compared with the ther technical methods for the preparation of dicyanliamide in which ammonia or solid zinc cyanamide are sed as accelerators in solutions of cyanamide. The inc cyanamide method is shown to be mainly a case f heterogeneous catalysis, the reaction velocity being ractically independent of the rate of stirring. The elocity increases more rapidly than the amount of atalyst added. In the authors' method of polymerising alcium cyanamide solutions the rate of formation of icyandiamido is increased by the presence of calcium hloride. A study of comparative yields shows that the ew method is not inferior to the others as a technical rocess for the manufacture of dicyandiamide.—W. H. P.

itrogen ; Absorption of —— by calcium. R. Brandt. Z. angew. Chem., 1914, **27**, 424.

ALCIUM, in pieces weighing 3 to 5 grms., is completely conerted into Ca_3N_2 on heating to 400°—500° C. in nitrogen. he pieces retain their form. The velocity of the reaction ncreases from 300° to 440° C., then decreases and is ero at about 800° C., the melting point of calcium. bove this temperature, the velocity again rises to a onsiderable value.—A. T. L.

Preparation of anthraquinone, Aniline Black, Indulines, etc.] Magnesium chloride. II. Its effect on the oxidising action of chlorates and nitrates. Hofmann and others. *See* IV.

itchblende discovery in India. Morning Post, July 4, 1914. [T.R.]

EPOSITS of pitchblende have been discovered in a pegatite to the east of Banckhap, in the Gaya district of ihar. At present between 8 and 9 cwt. has been raised. amples have been found to contain 83·39% of U_3O_8, and 0 to 315 mgrms. of hydrated radium bromide per metric n.

otash salts in Spain ; Discovery of ——. Board of Trade J., July 9, 1914. [T.R.]

XTENSIVE deposits of potassium sulphate and carbonate ve been discovered near Cordona (40 miles north-west Barcelona). The deposits are of great thickness and gin about 200 feet below the surface.

Sodium nitrate, borax, and phosphate in Chile. Oil, Paint, and Drug Rep., June 22, 1914. [T.R.]

The production of sodium nitrate in Chile during 1913 was valued at nearly £22,000,000, and of borax at over £400,000. A large, rich deposit of phosphate has been found at the mouth of the Huasco River, about 100 miles north of Valparaiso.

Russian chemical industry in 1913. Board of Trade J., June 11, 1914. [T.R.]

The past two years have been favourable for the chemical industry of Russia. A number of works have had to increase their share capital, and in 1913 four new companies were formed with a total capital of £58,500 ; of this amount £50,000 is the capital of a company for the manufacture of soap and stearine. The production of sulphuric acid has increased particularly, following on an increased importation of pyrites from 104,400 tons in 1911 to 142,400 tons in 1913. The imports of other raw materials used in the chemical trade likewise show an increase. The chemical market has remained firm, and, as the home industry has been unable to supply all the demand, there has been a large increase during the past two years in the imports of chemical and pharmaceutical products.

Ammonium sulphate plant at Fushun, China. Board of Trade J., July 2, 1914. [T.R.]

A Mond gas plant is being installed at the Fushun coal mines in Manchuria, with a view to supplying power for use in generating electricity. This plant has been specially designed for the recovery of sulphate of ammonia, Fushun coal being particularly suitable for this purpose, and it is estimated that 250 tons of coal will be gasified per day, and that there will be a daily yield of about 12 tons of sulphate. The present intention is to sell this sulphate in Japan or California.

Patents.

Persulphuric acid and its salts ; Manufacture of ——. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 24,931, Nov. 1, 1913.

See Ger. Pat. 271,642 of 1913 ; this J., 1914, 484. Alloys of tin with aluminium or of either or both of these metals with magnesium, zinc, cadmium, silicon, copper, manganese, etc., may also be used as electrode material in producing persulphuric acid as well as persulphates.
—T. F. B.

Sodium carbonate crystals ; Process for producing ——. M. Spazier, Los Angeles, Cal., U.S.A. Eng. Pat. 29,827, Dec. 27, 1913.

Soda ash is agitated with cold water (*e.g.*, 180 gallons to 600 lb. of ash), the solution exposed to the air, preferably for 70 hours, and the separated crystals drained. A clear granulated product is obtained.—F. Sodn.

Cyanides ; Process for forming ——. J. E. Bucher, Providence, R.I., U.S.A. Eng. Pat. 11,797, Feb. 24, 1913.

See U.S. Pat. 1,094,976 of 1914 ; this J., 1914, 692. The alkali carbonate may be replaced by an alkali or alkaline earth metal or compound. If the metal is used, it may be brought into the reaction in the form of vapour.
—T. F. B.

Silicic acid ; Manufacture of chemically pure soluble ——. Ges. fur Elektro-Osmose m. b. H., Frankfort on Maine, Germany. Eng. Pat. 9237, April 14, 1914. Under Int. Conv., April 14, 1913.

An alkali silicate solution is subjected to the action of an electric current in the anode compartment of a diaphragm cell, the electrodes being perforated sheets lying close against the diaphragm wall, and the diaphragm itself (*e.g.*, of carborundum and corundum as described in

Fr. Pat. 426,072 of 1911; this J., 1911, 942) of such potential that only the alkali migrates through it. The silicic acid obtained is rendered free from other acids by anodic purification, preferably with a diaphragm of parchment paper; it is permanent when properly stored. —F. SODN.

Nitric acid; Manufacture of ——. C. Casman, Bercham, Belgium. Eng. Pat. 11,296, Sept. 5, 1913.

SEE Fr. Pat. 457,800 of 1913; this J., 1913, 1009.—T. F. B.

Hydrochloric acid and potassium bisulphate from potassium chloride and sulphuric acid; Process for the continuous production of dry ——. T. Meyer, Offenbach, and A. Klages, Magdeburg, Germany. U.S. Pat. 1,099,451, June 9, 1914. Date of appl., Jan. 6, 1913.

SEE Ger. Pat. 261,411 of 1911; this J., 1913, 826.—T.F.B.

Ammonia; Manufacture of ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 24,823, Oct. 31, 1913.

SEE Fr. Pat. 466,303 of 1913; this J., 1914, 645.—T. F. B.

Nitrate of ammonia; Process for the manufacture of ——. J. M. Herschell, London. From Wülfing, Dahl und Co., Barmen, Germany. Eng. Pat. 26,233, Nov. 15, 1913.

SEE Fr. Pat. 465,683 of 1913; this J., 1914, 644.—T. F. B.

Fluoride of sodium and fluoride of aluminium; Method of producing a double compound of ——, *with a simultaneous gaining of colloidal silicic acid.* A. Humann and E. Teisler, Dohna, Saxony. Eng. Pat. 12,626, May 30, 1913.

SEE Fr. Pat. 458,750 of 1913; this J., 1913, 1067.—T. F. B.

Aluminium acetate compounds; Process for the manufacture of ——. S. Sokal, London. From Kalle und Co., Akt.-Ges., Biebrich-on-Rhine, Germany. Eng. Pat. 15,020, June 30, 1913.

SEE Ger. Pat. 272,516 of 1912; this J., 1914, 568.—T. F. B.

Hydrosulphite of sodium; Process for manufacturing —— *based on the expansion of the liquefied sulphur dioxide.* L. Descamps, Lille, France. Eng. Pat. 19,404, Aug. 27, 1913. Under Int. Conv., Aug. 27, 1912.

SEE Fr. Pat. 459,144 of 1912; this J., 1913, 1155.—T. F. B.

Barytes; Method of separating —— *from ores.* C. J. Greenstreet, Webster Groves, Mo. Reissue No. 13,735, May 26, 1914, of U.S. Pat. 1,069,545, Aug. 5, 1913. Date of appl., Jan. 15, 1914.

SEE this J., 1913, 871.—T. F. B.

Iron from liquids; Process of eliminating ——. H. Haekl and H. Bunzel, Heufeld, Germany. U.S. Pat. 1,100,675, June 16, 1914. Date of appl., May 27, 1913.

SEE Fr. Pat. 459,576 of 1913; this J., 1913, 1156.—T. F. B.

Hydrogen peroxide; Production of stable solutions of —— *containing caustic alkali.* G. W. Johnson, London. From Deutsche Gold- und Silber-Scheide-Anstalt, vorm. Roessler, Frankfort-on-Maine, Germany. Eng. Pat. 13,751, June 13, 1913.

SEE Fr. Pat. 460,959 of 1913; this J., 1914, 76.—T. F. B.

Nitrous oxide; Process for the manufacture of ——. C. Torley, Brussels, and O. Matter, Troisdorf, Germany. U.S. Pat. 1,098,305, May 26, 1914. Date of appl., Oct. 21, 1913.

SEE Eng. Pat. 11,828 of 1913; this J., 1913, 867.—T. F. B.

Nitrogen compounds; Process of making ——. O. Frank and O. Fincke, Berlin. U.S. Pat. 1,101,424, June 23, 1914. Date of appl., Feb. 10, 1912.

SEE Fr. Pat. 439,244 of 1912; this J., 1912, 738.—T. F. B.

Graphites; Treatment of ——. E. N. Lainé, Paris. Eng. Pat. 5798, March 7, 1914.

SEE Fr. Pat. 464,642 of 1913; this J., 1914, 550.—T. F. B.

Hydrogen; Process for the preparation of —— *by autocombustion.* G. F. Jaubert, Paris. U.S. Pat. 1,099,446, June 9, 1914. Date of appl., March 1, 1912.

SEE Fr. Pat. 438,021 of 1911; this J., 1912, 536.—T. F. B.

Metal adsorptions; Method for producing ——. B. Schwerin. Assignor to Ges. f. Elektro-Osmose m. b. H., Frankfort-on-Maine, Germany. U.S. Pat. 1,098,176, May 26, 1914. Date of appl., Jan. 4, 1913.

SEE Ger. Pat. 252,372 of 1912; this J., 1912, 1201.—T.F.B.

VIII.—GLASS; CERAMICS.

PATENTS.

Glass plates; Process for making ——. A. W. Mathys, London. From Bicheroux, Lambotte und Co., Ges. m. b. H., Herzogenrath, Germany. Eng. Pat. 9490, April 16, 1914.

THE chilled or irregular edges formed during flattenin are removed from the plate by a cutting device operatin whilst the plate is being rolled.—F. SODN.

Plate-glass; Apparatus for the manufacture of raw —— M. Bicheroux, Assignor to Bicheroux, Lambotte un Co., Ges. m. b. H., Herzogenrath, Germany. U.S. Pat 1,101,392, June 23, 1914. Date of appl., Jan. 20, 191

SEE Eng. Pat. 9490 of 1914; preceding.—T. F. B.

Fireproof materials from quartz and the like; Method producing ——. W. Boehm, Berlin. U.S. Pa 1,099,113, June 2, 1914. Date of appl., Oct. 30, 1913.

SEE Fr. Pat. 463,147 of 1913; this J., 1914, 354.—T. F.

Enamels; Cloudening agent for producing cloudening effe in white —— *and process of producing the same.* Kreidl, Vienna. U.S. Pat. 1,101,455, June 23, 191 Date of appl., March 28, 1912.

X.—METALS ; METALLURGY, INCLUDING ELECTRO-METALLURGY.

tinum ; Assay of crude ——. M. Schwitter. Eng. and Min. J., 1914, **97**, 1249—1250.

ENTY-FIVE grms. of the nuggets are digested with 200 c.c. *aqua regia* ($1HNO_3 : 3HCl$) on a water bath for one hour, l then boiled gently for 2 hours. The solution is anted and again boiled to dissolve any finely divided tal in suspension. The *aqua regia* treatment is repeated the residue, and the mixture is diluted with water and wed to settle overnight. The clear solutions are anted, and the last portion filtered, into a graduated 0 c.c. flask, the filter being washed till colourless. *miridium.*—The residue from the acid treatment is scori- l with 10—15 grms. of test lead and enough litharge fill the scorifier. The button is cleaned with as little nmering as possible and dissolved in nitric acid (1 : 3). solution containing lead is filtered, the filter washed from lead, and dried. The osmiridium is separated as pletely as possible from the paper, the latter is burned the ash added to the metal, which is weighed. *tinum.*—25 c.c. of the filtrate are evaporated to dryness, residue heated for 1 hour, with occasional stirring, h 5 c.c. of hydrochloric acid (1 : 9), 20 c.c. of water, and ms. of ammonium chloride, allowed to stand overnight, chloroplatinate filtered off, washed with 20% nonium chloride and ignited, very gently at first, in nnealing cup. The metal contains most of the iridium ; quantity of the latter, if not more than 5%, can be ged with sufficient accuracy from the colour of the roplatinate, 0·2% Ir sufficing to impart a decided red . *Gold.*—The filtrate from the platinum determination eated with 5 grms. of ferrous sulphate, the gold filtered and ignited in an annealing cup. *Palladium.*—The ate is treated with one-fifth of its volume of hydrochloric . and precipitated with 10% potassium iodide solution, ops at a time, till no further black precipitate (PdI_2) s. The liquor is boiled, cooled, and filtered, the ipitate washed with dilute hydrochloric acid (1 : 4) l free from iron, ignited in porcelain in a muffle, then med with a few drops of formic acid to reduce any e, dried, and weighed. *Rhodium.*—The filtrate from palladium is reduced, while hot, with zinc, and the llic precipitate digested for 10 mins. with 25 c.c. of e nitric acid (1 : 3) on a water-bath ; the residue is ed, reduced in hydrogen, and weighed as rhodium ; ntains the last traces of iridium.—W. R. S.

dium, palladium alloys, and hydrogen. A. Sieverts. Z. angew. Chem., 1914, **27**, 337—338.

isotherms and isobars of hydrogen absorption by dium of various forms are similar, but the quantitative ts vary greatly with the nature of the palladium. absorption at atmospheric pressure increases with erature between 100° and 140° C., then decreases ually, and between 700° and the m. pt. (1550° C.) s very little At 1550° the absorptive power of the en metal is lower than that of the solid. At low ures the hydrogen absorption varies with the square of the pressure. The dissociation constant of the lved hydrogen is a maximum at 137° C. and varies between 300° and 800° C. The velocity of absorption of hydrogen by palladium wire increases rapidly with temperature ; above 300° absorption is instantaneous, and at low temperatures it can fall to zero. The absorptive power of commercial palladium wire is in all cases 10 to 20% lower than that of the pure wire ; this is probably due to the presence of platinum and ruthenium, since it is found that palladium-platinum alloys absorb less hydrogen at lower temperatures and higher contents of platinum. On the other hand, silver and gold (which do not dissolve hydrogen) increase the absorptive power of palladium for hydrogen, with increasing amounts of metal, to a maximum ; further addition of silver or gold reduces the absorptive power : in this case, the hydrogen absorption rises with decreasing temperature.—T. F. B.

[*Gold and silver.*] *Precipitation from cyanide solutions.* H. A. Megraw. Eng. and Min. J., 1914, **97**, 1232—1238.

The solution to be precipitated should be quite clear. Four precipitating agents are in use ; the electric current. charcoal, aluminium, and zinc. *Electrolysis* was employed in South Africa for several years. Iron anodes and lead cathodes were used, the deposited metal being stripped off the latter from time to time. By using relatively high current density the metal is precipitated as a sludge or slime which can be wiped from the cathode. Electrolysis regenerates an appreciable amount of cyanide, but the precipitate is hard to melt and contains all the metals taken up by the cyanide liquor. The use of *charcoal* is restricted. That made from soft wood is most efficient ; 100 lb. of charcoal, twice re-burned, will carry 30—40 ozs. of metal, and the ash is easily melted into bullion. The action of charcoal is probably due to occluded gases (this J., 1913, 1014). *Aluminium* has been introduced recently in several mills (this J., 1913, 660). It does not combine with the cyanide as does zinc, and thus regenerates a certain quantity of the salt. *Zinc* is the most generally used precipitant, either in the form of shavings, or better, of dust (this J., 1914, 263). A slight excess of cyanide must be present to prevent precipitation of zinc hydroxide. In cyaniding old amalgamation tailings, mercury is dissolved to a large extent and almost entirely precipitated by zinc ; it may be recovered by retorting the precipitate. Zinc-shavings are usually screened in recovering the values, so as to remove the coarser metal which is returned to the precipitation boxes. The finer portion (60- to 80-mesh) is generally treated with acid, the residue constituting high-grade material which is added to the undersize from the finer screens. Zinc-dust precipitate only requires filter-pressing before melting down (this J., 1914, 423).—W. R. S.

Copper ; Oxidation and reduction of ——. J. Joannis. Comptes rend., 1914, **158**, 1801—1804.

The velocity of reduction of copper oxide by hydrogen is practically constant over a considerable range of pressure ; that of the oxidation of copper by oxygen diminishes rapidly from the beginning of the reaction. The diminution is not caused by the fall in pressure but by the layer of solid oxide which interferes with further reaction.—W. H. P.

Metals ; Colouring ——. *IV. Colouring copper grey-black with permanganate solution.* E. Groschuff. Deutsche Mechan.-Zeit., 1913, 233—239. Chem. Zentr., 1914, **1**, 2123—2124. (See also this J., 1910, 1312 ; 1913, 538.)

Copper and heavily copper-plated articles can be coloured grey-black by treatment for 10—15 mins. at 100° C. in a solution of 12 grms. $CuSO_4.5H_2O$ and 1·5 grms. $KMnO_4$ in 100 c.c. H_2O. Passive copper and copper which has been treated with boiling sodium hydroxide solution cannot be coloured in this way. Red brass castings and tombac may be coloured in a somewhat similar way. Brass is coloured grey-black but the coating does not adhere well. Zinc becomes covered with a firmly adherent shiny black coating. Tin, aluminium, lead, and tin- and aluminium-bronzes are not coloured satisfactorily.—A. S.

Copper and copper alloys; Colouring —— brown by copper sulphate solutions. E. Groschuff. Das Metall, 1914, 37—38. Chem. Zentr., 1914, 1, 2124.

Metallic copper when treated with a boiling solution of 12 grms. $CuSO_4,5H_2O$ in 100 c.c. H_2O, becomes covered with a dull violet grey coating consisting of a layer of brown cuprous oxide and a superimposed deposit of a greenish basic copper salt. This greenish deposit may be masked by coating with Japan lac, greasing with vaseline, wax, etc., and a fine reddish brown to chocolate brown colour is thus obtained. The copper surface must be free from traces of fat or oxide. The colour may be modified by varying the duration of immersion in the solution and by suitable after-treatment (see also preceding abstract). A thicker, more yellowish brown colour, without any dull bluish tinge, is obtained if potassium or sodium chlorate be added to the solution. Copper alloys, such as tombac, red brass, brass, and aluminium-bronze, may be coloured in a similar manner. A dull copper-red to reddish brown colour is obtained on tin-bronze. Soft solder is not coloured and does not interfere with the colouring of copper soldered therewith.—A. S.

Reduction by hydrogen of copper and nickel oxides in presence of a dehydrating agent. E. Berger. Comptes rend., 1914, **158**, 1798—1801.

The reduction of copper and nickel oxides is greatly accelerated when a dehydrating agent (anhydrous baryta) is present to absorb the water as it is produced. The velocity curve for copper oxide at 100° C. shows first an irregular delay before the reaction begins and then a steady reduction to the metal without any sign of an intermediate stage. The curves for nickel oxide at 182° C. and 209° C. both indicate the existence of Ni_2O.—W. H. P.

Copper and nickel; Hardness and modulus of elasticity of isomorphous mixtures of ——. N. Kurnakow and J. Rapke. J. Russ. Phys.-Chem. Ges., 1914, **46**, 380—394. Z. anorg. Chem., 1914, **87**, 269—282.

The hardness of Cu-Ni-alloys, a continuous series of solid solutions, was determined by the Brinell method, using a ball of 9·52 mm. diam. and a load of 485 kilos. The modulus of elasticity was determined by Lermantow's method (Chowlson, Lehrbuch der Physik, I., 703). The results were as follows :—

Ni, %	0	10	20	30	39·7	45·6	59·0	72·0	80	89·4	1
Hardness, kilos. per sq. mm.	32·4	43·8	54·1	66·1	72·1	81·3	77·3	65·2	74·8	62·3	6
Modulus of elasticity, kilos. per sq. mm.	11,110	11,948	12,590	13,492	14,569	14,855	16,710	17,150	18,849	18,182	20,

It may be deduced from the relaxation theory of Clerk-Maxwell that the hardness of a solid is proportional to the product of the modulus of elasticity and the time of relaxation (time required for equalisation of internal strains), and hence that an increase of hardness may be due to an increase of the modulus of elasticity, or of the time of relaxation, or of both. In the case of Cu-Ni-alloys the increased hardness must be due to increase in the time of relaxation, for the modulus of elasticity can be calculated from the values for the component metals, whereas the curve representing the hardness passes through a maximum. In the case of brass, bronze, steel and other copper and iron alloys also, increased hardness is due to increase in the time of relaxation. Hardened steel, for instance, has a lower modulus of elasticity than soft iron. A substance is more brittle the greater its time of relaxation. It is suggested that manganese-nickel- and other special steels may belong to the class of alloys in which increased hardness is due to increase in the modulus of elasticity. Alloys belonging to this class are of great practical importance because increased hardness is not accompanied by any considerable increase of brittleness.

In the preparation of the copper-nickel alloys it was found necessary to add a quantity of manganese equal to 1·6—1·8% of the weight of the nickel in order to obtain alloys in which no cracks were developed on rolling.—A. S.

Brass foundries; Application of producer gas to ——. E. Bulmahn. Trans. Amer. Inst. Metals, 1914, 7, 288—31

The use of producer gas for melting brass, for drying core and for power purposes in the brass foundry is advocate It is essential that the gas be free from tar. At t Langsenkamp-Wheeler Brass Works, Indiania, installation of four Westinghouse double-zone sucti producers, each having a capacity of 500 lb. of coal per ho has been in operation for 4 years with satisfactory resul In the double-zone producer, the raw fuel (bitumino coal) is carbonised in the upper section and the residu incandescent coke converted into gas in the lower secti The gas is drawn off between the two sections and serv to generate steam in a vaporiser arranged around the t of the lower section: it is free from tar and is ready use after passing through a wet coke scrubber and a d scrubber. The gas has a calorific value 110—115 B.Th.U. per cb. ft. and in order to obt the required temperature in the furnace (vi 2500°—2600° F., 1370°—1430° C.), both the gas a air are preheated by the waste gases from the furna Curves are given showing the relative cost of produ gas compared with ordinary lighting gas and with fuel. In melting red brass with producer gas the loss metal was reduced to 0·75—1%.—A. S.

Alloys; Electrolytic separation of —— and their meta graphic and mechanical investigation. III. Attempts produce zirconium-, aluminium-, antimony- and chromi bronzes. R. Kremann, J. Lorber, and R. Ma Monatsh. Chem., 1914, **35**, 581—601.

Attempts to deposit zirconium electrolytically eit alone or alloyed with mercury or copper were unsuccess From a bath containing zirconium oxychloride (with of iron as impurity) and copper sulphate an alloy obtained which left a residue insoluble in nitric acid. this proved to be iron in a very resistant (passive) condit Similar results were obtained with aluminium, the deposi copper containing a rather large percentage of cupr oxide as well as a trace of iron. When purified alumini sulphate was used no iron separated. Antimony-bro were obtained from baths containing tartar emetic. T differed considerably in character from the correspon tin-bronzes, showing a much smaller tendency to f solid solutions. The photomicrographs showed q distinctly the existence of two constituents. M containing 2·22% Cr and 2·2% O was obtained fro bath containing copper and chromium salts; possibly chromium was present as hydroxide.—W. H. P.

Zinc blende and lead sulphide; Rate of solution of — in dilute sulphuric acid. F. Rosenkränzer. Z. an Chem., 1914, **87**, 319—334.

Weighed quantities, usually 10 grms., of powd mineral, in grades composed of particles of 1·13, 0·90 0·75 mm. diam. respectively were agitated at cons temperature in a stoppered bottle containing a kn volume of dilute sulphuric acid (1·25, 0·125 or 0·0125%) practically no air. The small amount of hydr sulphide formed was measured at suitable intervals by methylene blue colorimetric method (this J., 1914, The amounts obtained were seldom more than a mgrms., but the results showed clearly that the amou hydrogen sulphide formed depended upon the tim reaction, the concentration of the acid, the area of particles of mineral, and the actual quantity of mi present, and was independent of the amount of agita Four different types of blende and one of galena were and although each mineral had its own rate of sol the temperature coefficient of the reaction was the sam

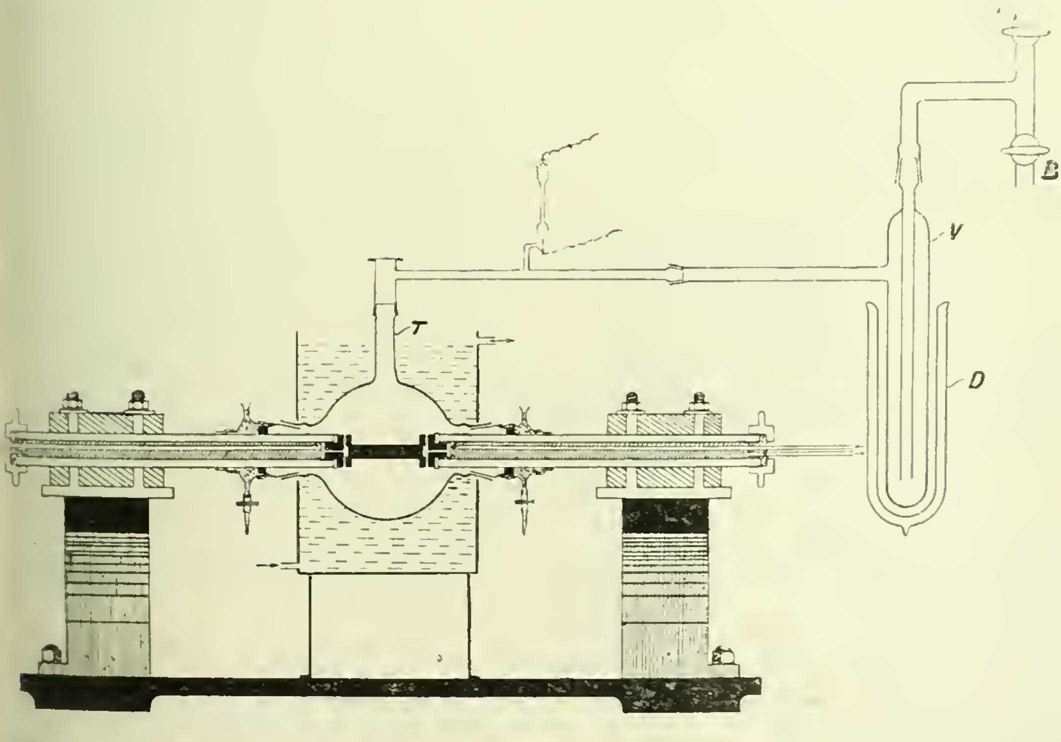
. In heterogeneous reactions the determining factor is ally diffusion, the velocity being primarily determined the diffusion coefficient of the soluble reagent. In the sent case, however, the diffusion appears to be much re rapid than the preliminary reaction at the surface ich therefore determines the velocity of the whole cess.—W. H. P.

tals: Velocity of solution of —— in acids. I. Zinc. M. Centnerszwer and J. Sachs. Z. physik. Chem., 1914, 87, 692—762.

so which has been previously corroded so as to expose its ucture dissolves in acids more readily than the polished tal and hence the rate of solution of polished zinc reases steadily from the time of immersion up to a ximum. If a piece of metal which has been treated h 2N hydrochloric acid until this maximum is reached, hen immersed in fresh acid the velocity falls steadily, process of solution following the law of Boguski . the velocity of reaction is proportional to the face exposed and also to the concentration of the d). Sulphuric acid dissolves zinc more slowly than drochloric acid when the solutions compared have the ne hydrogen-ion concentration, suggestive of a specific ion of the anion of the acid upon the metal. Zinc tes prepared from the same casting dissolve with erent velocities owing to differences in crystal habit. the zinc is rubbed with emery paper before immersion the acid its rate of solution is much greater than when s polished with sand or filed. Treatment with emery o eliminates the "induction period" and the maximum ocity is attained at once. The finer the grain of the ery the more active the plate becomes. Another thod of "activating" the metal is to treat it with ine solution. The "black precipitate" which is med on the surface of metallic zinc during its solution acid accelerates the process of solution; when it is noved the velocity diminishes considerably. When c which has been made active is allowed to stand in the it loses some of its activity; in distilled water the ivity is retained for a long time. Metal which has once n active and allowed to become passive is more difficult to make active again than fresh metal. Rapidly cooled zinc has a longer "period of induction" than the slowly cooled metal, but after etching its surface it dissolves with the same velocity. The period of induction of slowly cooled metal is increased by heating at 400° C. for some time. The authors explain the phenomena observed on the assumption that ordinary chemically pure zinc is in the passive state and that the increase in the rate of solution is caused by activation of the metal. They also elaborate a general theory of passivity, based on the conception of the Helmholtz double layer, and including explanations of the influence of foreign metals and of mechanical and chemical treatment of the surface on solubility, the period of induction, the periodic fluctuations which often occur in the rate of solution, the passivifying of metals by oxidising agents and by polarisation, the corrosion of iron and other metals, the activation of metals by hydrogen, the specific influence of different electrolytes, and overvoltage.—W. H. P.

High temperatures; Special methods for the production of —— and the behaviour of certain metals, oxides and carbides. E. Tiede and E. Birnbräuer. Z. anorg. Chem., 1914, 87, 129—168.

The furnaces used in the work were the cathode ray furnace previously described and illustrated (this J., 1913, 796) and a modification of the Fischer and Tiede furnace (this J., 1911, 963) as illustrated in the figure. The heating element was a carbon boat held between the copper electrodes. Tungsten was so reactive at high temperatures that it could not often be used. The apparatus was first exhausted as far as possible by a Gaede oil pump connected with A and then a high vacuum was produced by a Gaede mercury pump connected with B. The very high vacuum was maintained by the use of rubber rings between the glass and the metal which are cooled by means of mercury (represented by dots in the figure). The temperatures were usually measured by means of the Holborn-Kurlbaum optical pyrometer, and are therefore only approximate above 2000° C. The results obtained with the various metals, oxides, etc., investigated are summarised in the



following tables. The point at which evaporation commenced was determined by the appearance of a sublimate on the glass bulb.

Oxide.	Temperature of volatilisation.	Melting point.	Colour of melt and sublimate.	Furnace used.	Remarks.
BeO	—	about 2400°	white like porcelain	Cathode ray	Evaporated just before melting.
MgO	about 2000°	did not melt	—	Both furnaces	Dissociated into its elements.
CaO	1690°	do.	—	Cathode ray	———
Al_2O_3	1750°	1890°	colourless, glassy	do.	Tendency for melt to crystallise.
La_2O_3	2000°	about 2000°	clear yellow melt	do.	Dissociated forming lower oxide.
ZrO_2	—	2430°	white opaque melt	do.	Evaporated just before melting and dissociated into its elements.
SnO_2	—	did not melt	—	do.	Dissociated forming lower oxide.
SnO	red heat	do.	black sublimate	do.	———
CeO_2	1875°	do.	transparent sublimate in crucible	do.	———
ThO_2	about 2000°	2000°	white opaque sublimate	do.	———
V_2O_5	did not evaporate	did not melt	—	do.	Dissociated probably to VO_2.
V_2O_3	red heat	do.	blue-black sublimate	do.	———
Ta_2O_5	did not evaporate	do.	—	do.	———
MnO	—	1650°	black	do.	Melt crystallised.

Charge of furnace.	Temperature at which volatilisation commenced.	Melting point.	Temperature of visible ebullition.	Furnace used.	Remarks.
Copper	960°	1085°	2000°	Resistance	In a carbon boat.
Silver	850°	968°	1950°	do.	do.
Gold	970°	1060°	2100°	do.	do.
Boron	—	2200°	—	Cathode ray	Impurities distilled out of the elemen before melting point determined.
Silicon	1350°	1350°	—	do.	
Tin	880°	—	—	Resistance	In carbon boat.
Tantalum	2200°	2475°	—	do.	Metal itself used as heating element.
Chromium	—	1420°		Cathode ray	Purified like B and Si.
Tungsten	2390°	—		Resistance	Metal itself used as heating element
Manganese	—	1290°	—	do	In a magnesia boat placed inside t carbon one.

In resistance furnace.

Oxide	Temperature of reduction by carbon.	Remarks.
BeO	2400°	Carbide volatilised.
MgO	—	Oxide dissociated into elements, the metal being highly pyrophoric.
CaO	1540°	Carbide dissociated at 800°.
Al_2O_3	1800°	Carbide volatilised.
B_2O_3	2400°	Carbide sublimed in metallic fibres.
MnO	1100°	Carbide dissociated at 1550°.
UO_2	1600°	Carbide volatilised.

N.B.—Of the resulting carbides, that of calcium dissociated at 800° C. in either furnace; SiC volatilised at 1650° C. in the resistance furnace, being dissociated into its elements; UC_2 melted at 2200° in the resistance furnace, and at 2260° C. in the cathode ray furnace, yielding a white, metallic, pyrophoric melt.

Cerium-iron alloys; Analysis of pyrophoric ——. H. Arnold. Z. anal. Chem., 1914, **53**, 496—503.

The alloy (0·5 to 1 grm.) is covered with water and dissolved in bromohydrochloric acid. If antimony is present potassium chloride (0·5 grm.) must be added before eliminating the silica and the temperature during this process must be carefully regulated. After eliminating the silica tartaric acid (3 to 5 grms.) is added and the solution poured into concentrated ammonia (50 c.c.). Ammonium sulphide solution (15 to 30 c.c.) is gradually added at about 60° C., with vigorous stirring. The precipitate of sulphides of iron, copper and zinc (aluminium remains in solution) is kept on the water-bath for about 2 hours with stirring, then filtered off and washed five or six times with warm water containing a little ammonia, ammonium sulphide and ammonium tartrate, with exclusion of air. (In presence of manganese a somewhat modified treatment is necessary at this stage, the iron is removed by extraction with ether from hydrochloric acid solution as described in this J., 1892, 940, and the oth metals are separated by known methods.) The ignit precipitate (treatment with nitric acid is necessary wh zinc is present) is dissolved in hydrochloric acid; the copp is precipitated and determined in 4% acid solution wi hydrogen sulphide and the iron with ammonia. If, ho ever, iron only is to be determined the sulphide precipita is dissolved forthwith in hydrochloric acid with t addition of a little potassium chlorate, and a volumet method applied. For determining cerium the filtr from the sulphide precipitate is kept on the water-bath two hours, evaporated to small bulk, treated for one h on the sand-bath in a round-bottomed Jena flask wi concentrated hydrochloric acid (10 c.c.) and potassi chlorate (2 grms.) in order to destroy the tartaric ac evaporated to dryness, and the residue heated for half- hour with concentrated hydrochloric acid (10 c.c.) a potassium chlorate (1 grm.). From the dilute acid solut of the residue the cerium is then precipitated in usual way by oxalic acid. The oxalate precipitate m if necessary, be freed from antimony and alumini by successive treatment with hydrogen sulphide a ammonia, the oxalic acid being first destroyed by the act of nitric acid.—J. R.

Tungsten in Bolivia. G. W. Wepfer. Eng. and Min. 1914, **97**, 1251—1252.

There are known at present approximately 90 depo of tungsten ores, the most important of which are situa in the departments of La Paz and Potosi. Exports w estimated at $89,932 (about £18,480) in 1911, and $114, (about £23,600) in 1912. The crushed ore is concentra on tables. Wolfram concentrates containing tin calcined and subjected to magnetic separation. So times silver occurs in the tungsten or tin ores.—W. R

XI.—ELECTRO-CHEMISTRY.

Aromatic hydrocarbons and phenols; Electrochemical oxidation of ——. F. Fichter and R. Stocker. Ber., 1914, **47**, 2003—2019.

THE electrolytic oxidation of benzene in sulphuric acid in presence of a platinium anode gave quinone as the main product, the chemical efficiency of the current being 5·3%. Maleic acid was obtained as a by-product. With a lead dioxide anode the chief products were quinone and quinol, and the efficiency was 21·3%. Under the latter conditions, using phenol instead of benzene, it was possible to increase the efficiency to 34·02% by suitably adjusting the conditions; in this case the quinone was completely reduced to quinol by means of sulphur dioxide. By reducing phenol in sulphuric acid with a platinised platinum cathode until the phenol completely disappeared, a yield of 3 grms. of cyclohexanol was obtained from 5 grms. of phenol. From this, by electrolytic oxidation in sodium carbonate solution with an anode of platinum gauze and using three times the theoretically requisite amount of current, 2·5 grms. of cyclohexanone was obtained, in addition to a small quantity of maleic acid. Toluene on electrolytic oxidation yielded toluquinone, toluquinol, phenol, quinol and benzaldehyde. o-Cresol gave toluquinol; *p*-cresol gave phenol and quinol; *p*-xylene gave small amounts of *p*-toluic aldehyde and various other oxidation products; and thymol yielded thymoquinol and other substances. Benzene and phenol thus give rise to identical end-products when oxidised electrolytically, the primary product from benzene being phenol itself. The action of anodic oxygen resembles that of hydrogen peroxide in converting nuclear —H into —OH. The authors compare these results, obtained with direct currents, to those obtained by Drechsel with alternating currents (J. prakt. Chem., 1884, [2] **29**, 229; 1886, **34**, 135; 1888, **38**, 65).—J. R.

XII.—FATS; OILS; WAXES.

Coconut oil; Glycerides of ——. A. Bömer. Chem.-Zeit., 1914, **38**, 844.

The composition of coconut oil was determined by distilling the oil in a high vacuum, followed by fractional extraction of the distillate and residue with acetone. The distillate was found to consist, in quantity equal to three-quarters of the original oil, of caprylolauromyristin, m. pt. 13°—15° C. There was also present myristodilaurin, m. pt. 33° C., and a smaller amount of laurodimyristin, m. pt. 37°—38° C. The distillation residue contained, besides the glycerides of oleic acid, which were not further examined, palmitodimyristin m. pt. 45° C. The insoluble portion of the distillation residue melted at 55° C. and was composed of impure stearodipalmitin. No indication was obtained of the presence in the oil of glycerides containing caproic or capric acids.—J. A.

Whale and other marine oils; Constants of ——. J. Lund. Seifensieder-Zeit., 1914, **41**, 414—415, 443—444.

The following results were obtained on examining sixteen different samples of commercial whale oil :—

	Saponif. value.	Iodine value.	Weight of 1 litre at 15° C.	Refractive index at 40° C.
			grms.	
Average	193·1	132·3	923·8	1·4679
Lowest	190·2	108·0	921·8	1·4659
Highest	197·0	161·7	927·3	1·4713

Other oils gave results as under :—

	Free fatty acids.	Saponif. value.	Iodine value (Wijs.)	Weight of litre at 15°C.	Refractive index (40° C.).
Japan fish oil ..	6·30	186·2	—	—	—

—J. A.

Insoluble bromide value of oils; Determination of ——. A. Gemmell. Analyst, 1914, **39**, 297—308.

The amounts of insoluble bromide obtained by the method of Hehner and Mitchell (this J., 1899, 77), and the modifications of Procter (this J., 1906, 798) and Sutcliffe (this J., 1914, 147) were found to vary with the quantities of oil and solvent used. The most concordant results (within 1 or 2%) were obtained by dissolving 2 grms. of the oil in 18 c.c. of ether and 2 c.c. of glacial acetic acid, and slowly adding a cooled mixture of 19 c.c. of ether and 1 c.c. of bromine. The varying quantities of bromine in the precipitates indicated that they consisted of mixtures of tetra- and hexa-bromo-glycerides in different proportions, and that the low percentage of bromine was not caused by the presence of a mixed glyceride. More concordant results were obtained by brominating the fatty acids than by brominating the glycerides, while the precipitates contained about 62·1% Br as compared with the theoretical 63·36% in linolenic hexabromide. The fatty acids from 5 grms. of the oil were dissolved in 100 c.c. of ether, and portions of 20 c.c. were mixed with 2 c.c. of glacial acetic acid, chilled in ice-water, brominated, and allowed to stand, and the insoluble bromides washed thrice in the flasks with 5 c.c. of cooled ether, transferred to weighed papers, dried and weighed. In this way the following results were obtained :—Raw linseed oils (7 samples), 32·60 to 37·65%; boiled linseed oils (6), 25·95 to 33·90%; soya bean oil, 4·10; rape oil, 2·35; walnut oil, 3·00% and tung oil, nil. Marine animal oils also gave concordant results, which were less affected by the solubility factor than in the case of vegetable oils. The percentage of bromine varied from 67 to 68·5% as against 70·96% required for $C_{17}H_{26}O_2Br_8$. Cod liver oil, 35·20; whale oil, 21·70; brown whale oil, 25·80; menhaden oil, 51·70; shark-liver oil, 17·70 and sperm oil 1·70%. No definite relationship could be traced between the iodine values and the percentages of insoluble bromides.—C. A. M.

Fat hardening [hydrogenation]; Osmium dioxide as a catalyser in ——. W. Normann and F. Schick. Arch. Pharm., 1914, **252**, 208—210. (See this J., 1913, 296.)

When unsaturated oils such as cottonseed or linseed oil are heated to 100° C. or over with osmium tetroxide the latter is reduced to the metallic condition, and it is the metal which acts as hydrogen-carrier in the hydrogenation of oils in presence of osmium dioxide.—F. Shdn.

Soya bean and oil trade of Dairen. Board of Trade J., July 9, 1914. [T.R.]

The export of soya beans from Dairen decreased slightly in 1913, owing to the demands of the local mills. These mills, 50 in number, consume about 450,000 tons of beans annually, producing over 50,000 tons of oil. The exports of bean cake amounted to 555,428 tons in 1913, compared with 469,089 tons in 1912: over 80% of this was sent to Japan, for use there or for transshipment to the United States. The exports of bean oil in 1913 increased by about 3000 tons; the export to Japan fell from 10,889 tons in 1912 to 3964 tons, and the export to China increased to 22,487 tons; heavy freight rates and high prices contributed to curtail the exports. An experimental mill has been erected at Dairen, in which the oil is to be extracted by benzine.

Soap making in Japan. Bd. of Trade J., July 9, 1914. [T.R.]

Soap, which prior to the imposition of the new Japanese tariff rates used to be imported to the extent of about £90,000 a year, was responsible last year for only £35,000, of which £19,000 was perfumed. The consumption of soap is increasing fairly rapidly, but the domestic production has advanced in an even greater proportion. A large British company's works are responsible for a big share of this production, but there are also several Japanese works making soap on a small scale. A great part of this is toilet soap, especially "floating" soap. Exports of toilet soap to China in 1913 were valued at £140,000 (compared with £26,000 in the preceding year), to which may be added £25,000 worth of soap sent to Formosa and Corea.

"*Acid clay*" [*oil decoloriser*] *in Japan.* Board of Trade J., July 9, 1914. [T.R.]

Large deposits of "acid clay" have been found in Echigo Province. The material resembles fuller's earth and is used for decolorising and deodorising oils. The price is about £3 per ton f.o.b. Yokohama, and about 1000 tons a month can be produced.

nufacture of lubricants or the like. Eng. Pat. 19,338. *See* IIa.

XIII.—PAINTS ; PIGMENTS ; VARNISHES ; RESINS.

llac ; Contributions to the examination of bleached ——. I. Wolff. Chem. Rev. Fett. Ind., 1914, **21**, 159—161. See also this J., 1914, 91.)

e following results were obtained in examining 65 ples of bleached shellac : Acid value 40—65 (two ples 70 and 76) ; saponif. value 200 to 250 (two ples 268 and 275) ; iodine value (Wijs) 4—10. Bleached llac always contains combined chlorine, and the sence of combined chlorine in resin mixtures may be sidered as an indication of the presence of bleached shellac. Free mineral acid may be present and acts injuriously on lacquered metal surfaces. It may be determined by dissolving 1—2 grms. of shellac in neutral alcohol, carefully diluting by shaking with 300—400 c.c. of water, and titrating with standard alkali till yellow if any red colour is produced with aminoazobenzene. A number of samples examined contained no free mineral acid, but some of these samples still discoloured brass ; it was found that if phenolphthalein were added to the liquid in which free mineral acids had been estimated as above and the liquid was then titrated with standard alkali till a red colour was produced, the acid value so obtained did not exceed 30 in the case of those samples suitable for lacquering brass, while unsuitable samples gave acid values more nearly approaching the acid value determined in alcoholic solution in the usual way, viz., 59—62.—R. G. P.

Terpene by-products in the manufacture of paper pulp. Luttringer. *See* V.

Patents.

Paints and printing colours ; Manufacture of ——. N. W. Turkin, Moscow. Eng. Pat. 23,128, March 7, 1913.

The colouring matter produced according to Eng. Pat. 5737 of 1913 (see page 742) is diluted with a carrier made by heating a resin and an animal fat and dissolving the product in naphtha, etc., a low-melting resin being used for the manufacture of artists' colours. For making printing colours animal fats, naphthalene, resins or small quantities of glucose are added to the mixture of dyestuff, Turkey red oil and alkali or alkaline earth metal salt before it is heated. After heating till the mass solidifies on cooling, the product is boiled with a fluid resin mixture made by boiling an animal fat and resin with a solvent, *e.g.* alcohol. —J. B.

XIV.—INDIA-RUBBER ; GUTTA-PERCHA.

Vulcanised rubber ; Swelling of ——. F. Kirchhof. Kolloidchem. Beihefte, 1914, 6, 1—22.

The degree of swelling of vulcanised rubber in a given medium (petroleum benzine, benzene, carbon bisulphide, carbon tetrachloride, chloro-derivatives of hydrocarbons) is different from that of raw rubber and depends primarily upon the degree of vulcanisation. The different media exhibit specific "swelling powers" which run parallel with their "solvent powers." The author expresses the quantity of liquid taken up when the swelling is at a maximum (Qu_{max}) as an exponential function of the specific gravity of the swelling medium: $Qu_{max}=K.S^x$, where S is 100 times the specific gravity and x is termed the "specific swelling exponent." The values of x for a number of liquids are: petroleum benzine, 1·206; oil of turpentine, 1·410; benzene, 1·735; carbon bisulphide, 1·754; trichloroethylene, 2·157; tetrachloroethane, 2·060; carbon tetrachloride, 1·784; pentachloroethane, 1·939. The total swelling is the sum of the imbibition (capillary absorption) and solution swelling, the latter being from 10 to 100 times greater than the former and being a function of the chemical character of the swelling medium. When vulcanised rubber is exposed to the vapour of the swelling medium, the only process is that of solution swelling, and a condition of equilibrium between the rubber and the vapour is established, which depends primarily upon the chemical nature of the swelling medium and is independent of the degree of vulcanisation. Swelling is accelerated by rise of temperature and proceeds more rapidly in the case of rubber which has not previously been extracted with acetone. There is a definite relation between the degree of swelling of vulcanised rubber and the vulcanisation coefficient

$$\left(\frac{\%\ \text{combined S in acetone-extracted rubber} \times 100}{\%\ C_{10}H_{16}}\right)$$

and between the latter and the extensibility, whence swelling may be regarded as extension of the rubber by the swelling medium. For example, $Qu.K^{\varepsilon}=k$ (constant), where Qu represents the volume percentage of swelling medium absorbed, K is the vulcanisation coefficient, and ε is an exponent which depends upon the nature of the swelling medium. For maximum swelling (24 hours) the values of k and ε for different media are: benzine, k 1225, ε 0·916; benzene k, 1386, ε 0·645; carbon bisulphide, k 1590, ε 0·71; carbon tetrachloride, k 3490, ε 1·016; and the vulcanisation coefficients calculated by means of the formula given above differ by only about 0·1—0·2 from those determined chemically. This is in agreement with the view that the whole of the sulphur not extracted by acetone is chemically combined. The relation between vulcanisation coefficient (K) and extensibility (D) is shown by the formula: $D.K^{\eta}=k$ (constant), where D represents the extension as a percentage of the original length, and η is an exponent which varies according to the load applied. For different loads the calculated values of k and η are given as:—5 kilos. per sq. cm., $k=285$, $\eta=0{\cdot}590$; 10 kilos. per sq. cm., $k=377$, $\eta=0{\cdot}356$; 20 kilos. per sq. cm., $k=449$, $\eta=0{\cdot}195$; and with the aid of these constants, the vulcanisation coefficient can be calculated from the observed extension. The whole of the experiments were made with samples (vulcanisation coefficients 1·2, 2·0, 3·5, 4·4, and 6·4 respectively) prepared by vulcanising for different lengths of time a mixture of 100 parts of plantation Para rubber and 12·5 parts of sulphur. (See also Caspari, this J., 1913, 1041.)—A. S.

PATENTS.

Latex; Treatment of [addition of preservative to] ——. S. C. Davidson, Belfast. Eng. Pats. 13,438, June 10, and 20,183, Sept. 6, 1913, and 764, Jan. 10, 1914. (See also this J., 1913, 98, 799.)

CRESOLS, cresylic acid or the higher tar acids are employed, preferably to creosote or carbolic acid, in the process described in the earlier patent (*loc. cit.*). For example:—Cresylic acid (108) or higher tar acids (120 parts) are dissolved in a solution of sodium hydroxide (40) or potassium hydroxide (56) in water (120 parts). To each 100 parts of "alkalised cresol" 1 part (or more) of liver of sulphur (or other alkali sulphide or polysulphide) dissolved in 15 parts (or proportionately more) of water may be added; and to each 100 parts of alkalised cresol, with or without added sulphide, 5 parts or more of 20—40% formaldehyde may be added. 1—5% of any of the above three mixtures either diluted or undiluted may be stirred into the latex. The latex is allowed to stand for 24 hrs., and after diluting with warm water, if necessary, is coagulated by the addition of 0·25—0·5% sulphuric acid (or other suitable acid). The "alkalised cresol" may be added at the same time as the acid coagulant.—E. W. L.

Rubber latex; Treatment [coagulation] of ——. A. E. Berry and A. Boake, Roberts and Co., Ltd., Stratford, Essex. Eng. Pat. 16,728, July 21, 1913.

IMMEDIATE coagulation of rubber latex is effected, and oxidation, darkening and the development of bacteria inhibited, by the addition of 0·1% of a freshly prepared, 5% aqueous solution of sulphur dioxide.—E. W. L.

Rubber; Process for incorporating albumin with ——. W. Esch. Ger. Pat. 273,482, Nov. 22, 1912.

AN albumin paste prepared with lime, magnesia, or the like, is incorporated with the rubber, and the product is treated with reagents (*e.g.* smoke or tannin solution) capable of rendering insoluble both the albumin and the lime or magnesia.—A. S.

Caoutchouc; Process for improving the properties of synthetic ——. J. Ephraim. Ger. Pat. 273,774, April 1, 1913.

STICKY or impure synthetic caoutchouc is mixed with sulphur (0·5—10%), with or without addition of oxygen- or nitrogen-compounds (*e.g.* sugars, naphthol, naphthylamine, rosin, coal tar, etc.), and heated to 110°—140° C. in absence of air, the heating being discontinued (*e.g.* after ¾—1½ hours) before the characteristic vulcanisation takes place. The physical properties of the caoutchouc are greatly improved, and foreign hydrocarbons can afterwards be easily removed by treatment with steam or by extraction; the treated caoutchouc is not sticky, can be easily dried by heating at 40° C. in a vacuum for 1—4 hours, and is not affected by exposure to the air.—A. S

Vulcanisation of natural or artificial caoutchouc; Proces for promoting the ——. P. A. Newton, London. Fron Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 12,777, June 2, 1913.

XV.—LEATHER; BONE; HORN; GLUE.

Gallic acid; Derivatives of ——. E. Schwenk. J. prakt. Chem., 1914, **90**, 53—60.

Attempts were made to prepare hexahydroxydiphenyldicarboxylic acid, which should yield ellagic acid by elimination of water, by boiling gallic acid and also its methyl ester with ferric chloride in aqueous solution and in glacial acetic acid. The ester gave a 20% yield of ellagic acid, but the gallic acid was unaffected. Methyl gallate on boiling for 3 hours with acetic anhydride gave triacetylmethylgallate crystallising in fine rhombs, m. pt. 120°—122° C. The corresponding ethyl ester also crystallises in well-formed rhombs, m. pt. 123°—125° C. The methyl ester of dibromogallic acid sinters at 155° C., and melts at 160°—161° C., which is considerably higher than previously recorded. On boiling with excess of acetic anhydride, it yields triacetyldibromomethyl gallate, which crystallises in white rhombs, m. pt. 150°—152° C.—T. C.

Leather; Definition of adulterated or loaded ——. *Union of South Africa.* Board of Trade J., July 2, 1914. [T.R.]

The definition of "adulterated or loaded leather" has been revised, and now reads as follows: " 'Adulterated or loaded leather' shall mean leather (other than chrome and other mineral and combination leathers) that contains more than 3% of mineral ash, or more than 2% of glucoses and dextrinoids, or any organic matters, other than pure tannins, fats, oils, wax and stearine, that are essential to the manufacture of leather. Chrome and other mineral and combination leathers shall not, however, have added thereto, or be loaded with, barium, lead or tin compounds, or magnesium sulphate, or sodium sulphate."

Patents.

Leather; Manufacture of ——. Anhydrat-Lederwerke A.-G. Ger. Pat. 273,652, Dec. 15, 1911.

Hides or skins are dehydrated by means of a suitable liquid, *e.g.* alcohol (see Fr. Pat. 427,614 of 1911; this J., 1911, 1129), and then, either directly or after a preliminary tanning process, are treated with a fused mass, consisting of artificial asphaltum (petroleum pitch), paraffin, ceresin, or the like, or mixtures thereof, having a melting point higher than the temperature to which the leather is to be subjected. The dehydrated hide or dried chrome leather may be impregnated with an anhydrous solvent of the asphaltum or the like, or with a solution of a tanning material in an anhydrous solvent which is also a solvent of the asphaltum, before immersion in the latter. Preferably the dehydrated skin or chrome leather is treated in a solution of natural or artificial asphaltum or rosin and then in a fused mixture of petroleum pitch of high-melting point with boiled linseed oil or petroleum pitch of low melting point.—A. S.

Chrome leather; Manufacture of ——. Anhydrat-Lederwerke A.-G. Ger. Pat. 274,418, Aug. 16, 1912. Addition to Ger. Pat. 273,652.

The leather as it comes from the tanning bath, and without being fat-liquored, is dehydrated by immersion in alcohol, acetone, or the like, and can then be further treated as desired, *e.g.* according to the process described in the chief patent (see preceding abstract). The finished leather is specially suitable for the manufacture of protective bands for automobile tyres, which can be fixed to the rubber by the vulcanisation process without being first extracted with a fat-solvent as is necessary in the case of ordinary chrome-leather.—A. S.

Chrome tanning; Process of ——. F. Hirsch. Ger. Pat. 274,549, Oct. 18, 1913. Addition to Ger. Pat. 271,585.

A stoichiometrical mixture of sodium sulphite or bisulphite and an aluminium salt, without addition of acid, is used instead of the aluminium bisulphite specified in the chief patent (this J., 1914, 559) for reducing the chromic acid or its salts.—A. S.

Tanning extracts; Process of making ——. M. Hamel. Grünau, Germany. U.S. Pat. 1,098,318, May 26, 1914. Date of appl., July 13, 1909.

See Fr. Pat. 405,110 of 1909; this J., 1910, 227.—T. F. B.

Leather and the like; Method of subjecting lacquered —— to the light treatment. A. Junghans, Schramberg, Germany. U.S. Pat. 1,099,378, June 9, 1914. Date of appl., Feb. 24, 1912.

See Eng. Pat. 10,971 of 1912; this J., 1912, 691.—T. F. B.

Gelatin; Manufacture of ——. H. Bunzel, Heufeld, Germany. Eng. Pat. 24,135, Oct. 24, 1913. Under Int. Conv., Oct. 28, 1912.

See Fr. Pat. 460,611 of 1913; this J., 1914, 95.—T. F. B.

XVI.—SOILS; FERTILISERS.

Nitrification and denitrification; Influence of organic matter on —— in arable soils. C. Barthel. Meddelande No. 83 från Centralanstalten för försöksväsendet på Jordbruksområdot, Stockholm, 1913. Biedermann's Zentr., 1914, **43**, 372—373.

In the presence of certain easily soluble organic nitrogen compounds (*e.g.* peptones, amides), nitrification does not take place till the organic matter is entirely destroyed. Certain non-nitrogenous substances (*e.g.* dextrose) have also a distinct retarding influence on nitrification even when present only in small quantities, although they assist denitrification. Organic matter which is not readily soluble has no great influence.—W. H. P.

Soil micro-organisms; Action of mineral fertilisers on some ——. C. Lumia. Atti R. Accad. dei Lincei, Roma, 1914, **23**, I., 738—746.

A definite quantity of bakers' yeast was added to tubes containing a nutrient solution in some cases free from potassium and phosphorus compounds and in others containing definite quantities of one or other or both of these. The tubes were inverted over mercury in a thermostat at 28° C. and the volume of carbon dioxide produced was observed. The results are tabulated. In absence of potassium compounds or of phosphate the yeast was practically inactive. In presence of potassium sulphate, mono-, di-, and tri-calcium phosphates had a favourable action nearly identical with that of dipotassium phosphate. Basic slag also gave favourable results. Superphosphate impeded the fermentation owing to its content of free acid, but gave good results in presence of calcium carbonate. Potassium chloride behaved similarly to potassium sulphate, but finely-ground leucite, in presence of tricalcium phosphate was inactive. It is suggested that experiments of the kind described would furnish useful information as to the comparative availability of insoluble constituents of fertilisers and soils.—A. S.

Absorption of nutritive substances by plants; Influence of a continuous electric current on the ——. Chouchak. Comptes rend., 1914, **158**, 1907—1910.

Small plants of wheat were carefully washed, threaded on platinum wires, and placed in a weak solution of certain nutritive salts in such a manner that a small continuous electric current could be passed through the plants and the solution. The absorption of either the cation or the anion of ammonium phosphate or nitrate, and potassium nitrate from solutions containing 1 to 3 mgrms. of the salt per litre was accelerated by a current of 0·5 to 250 micro-ampères.—F. Shdn.

Manures; Duration of action of ——. A. D. Hall. J. Roy. Agric. Soc. Eng., 1913. J. Board Agric., 1914, **21**, 242—243.

The results of long-continued experiments upon the Little Hoos Field, Rothamsted, show that among nitrogenous fertilisers, ammonium compounds and sodium nitrate have no perceptible action after the first year ; Peruvian guano, rape-cake and similar fertilisers containing proteins produce a slight effect after the first year and none after the second ; and fertilisers of the wool, hair, and bone class are slow-acting and non-wasting, their effect persisting for at least four years. In the case of farmyard manure, nitrogenous compounds derived from the consumption of cakes and other concentrated feeding stuffs have no effect after the second year, but compounds derived from straw and the undigested residues of coarse fodders, such as hay, have an appreciable value for at least four years. It is suggested that, especially on rich soils, it would be advantageous to grow a "catch crop" before the winter, so that residues of active nitrogenous fertilisers, otherwise wasted, would be converted into insoluble plant material to be subsequently ploughed into the soil.—A. S.

Lime and magnesia in the nutrition of plants ; Action of ——. E. Haselhoff. Landw. Jahrbb., 1913, **45**, 609—633. Chem. Zentr., 1914, **1**, 2068.

The results of pot experiments, extending over 3 years, with barley, beans, grass and mustard on soils of various kinds, were in agreement with field trials, and showed that Loew's hypothesis that for every kind of plant there is a definite ratio of lime to magnesia necessary to obtain the maximum yield, is not of general application.—A. S.

Phosphate in basic slag ; The Wagner test as a measure of the availability of the ——. H. E. Jones. J. Board Agric., 1914, **21**, 201—206.

The results obtained in the Wagner method of determining the citric-soluble phosphate represent a condition of equilibrium. If the solution be removed and the residue again treated with citric acid, a further quantity of phosphate is dissolved, and by repeating the extractions practically the whole of the phosphate can be dissolved. When basic slag is used as a fertiliser the dissolved phosphate is removed from the sphere of reaction, passing into the plant by osmosis, and solution of the phosphate goes on continuously. Field trials were made with a sample of mineral phosphate and with two slags having widely differing contents of citric-soluble phosphate. The view that the content of citric-soluble phosphate is a better measure of the value of a slag than the content of total phosphate is confirmed, but the results with the mineral phosphate suggest that the amount of phosphate dissolved in two or three successive extractions is a better measure of the availability than the amount dissolved in a single extraction as in the Wagner test. —A. S.

Superphosphate and basic slag ; Influence of the granular condition of —— *on their manurial action.* Miknowski-Pomorski. Z. landw. Versuchswesen in Oesterr., 1913, **16**, 1044. Biedermann's Zentr., 1914, **43**, 401—402.

When superphosphate is made into granules, 2 mm. in diam., by means of plaster of Paris or agar agar, its manurial value is not diminished, and in certain conditions is improved. The depth of its position in the experimental vessel is of more importance than the size of grain. Basic slag has a less pronounced action when the granules are enlarged.—W. H. P.

Barley ; Influence of potassium and phosphoric acid on the quality of brewing ——. L. Schül. Landw. Jahrbb., 1914, **45**, 641—712. Chem. Zentr., 1914, **1**, 2068.

It is concluded from the results of manurial experiments that to obtain barley of good quality, the nitrogen supplied must be at a minimum, and this is attained most surely by using an excess of potash and phosphatic fertilisers and no nitrogenous substances. Maximum yield of crop and highest quality are not compatible. Hence in some cases it is advisable to apply nitrogenous fertilisers to increase the yield. This can be done, up to a certain limit, without notably depreciating the quality.—A. S.

Purchase and use of liver of sulphur. See XIXb.

Patents.

Ammonio-fixing material for stables, privies, and the like ; Manufacture of an ——. J. F. Sacher. Ger. Pat. 272,531, June 26, 1913.

The material is prepared by treating sawdust or other cellulosic substances, with or without addition of ashes, sand, slag, or the like, with bisulphates or waste sulphuric acid, and to prevent any injurious action of the material on the walls, fittings, etc., of the stables, or on the cattle, it is mixed with organic substances insoluble in water, *e.g.*, oils, fats, resins, tar, or the like.—A. S.

Fertiliser rich in nitrogen ; Manufacture of a stable, neutral ——. V. Zelasko. Ger. Pat. 273,111, April 30, 1911.

The waste gases from the manufacture of sulphuric acid, containing about : N 95, O 4, H_2O 0·12, N_2O_5 (oxides of nitrogen) 0·8, and SO_2 0·01%, are led over molten calcium carbide in a rotary kiln, a muffle, or a furnace heated electrically by radiation. The furnace-charge and the gases pass through the furnace in opposite directions, and the free lime in the reaction product serves to dry the gases. The product (crude calcium cyanamide) contains no free lime, this having been converted by the acid constituents of the gases into nitrate and other salts.—A. S.

XVII.—SUGARS ; STARCHES ; GUMS.

Starch ; Changes in phosphorus content in the modification and diastatic hydrolysis of ——. *Studies on vegetable colloids. IV.* M. Samec. Kolloidchem. Beihefte, 1914, **6**, 23—54.

In previous communications evidence was given in favour of the hypothesis that starch is composed, at least in part, of a carbohydrate-phosphoric acid complex, corresponding to the amylopectin of Maquenne and Roux (see this J., 1913, 102, 954). By treatment with potassium hydroxide, the author has now separated starch into two parts, one richer in phosphorus and the other nearly free from that element. 100 grms. of air-dried starch suspended in 1 litre of water were treated with 9 litres of potassium hydroxide solution, the total concentration of alkali in the mixture being $1\cdot25.10^{-1}N$. After 1 hour, the mixture was made slightly acid with dilute sulphuric acid, diluted with 30 litres of water, allowed to stand for 24 hours, the liquid siphoned off, the residual amylopectin washed five times by agitating with water and siphoning off the clear liquid after settling, and then for 3 weeks in a slow current of water under toluene. The mixed wash-liquors were concentrated to 750 c.c. and this solution and also the amylopectin were dialysed for 2 months in presence of toluene, then evaporated to dryness and the residues dried at 105° C. The amylopectin (0·185% P_2O_5) was a transparent mass resembling gum arabic. The other constituent (amyloses) was a white powder (0·007% P_2O_5). 100 grms. of air-dried starch (13% H_2O) yielded 38 grms. of amyloses and 49 grms. of amylopectin. No liberation of phosphoric acid appears to take place in the diastatic hydrolysis of starch. All of the dextrins produced have the properties of electronegative colloids and contain combined phosphoric acid which is liberated on boiling with water.—A. S.

Starch granules : Action of diastase on ——. *I.* J. L. Baker and H. F. E. Hulton. Chem. Soc. Trans., 1914, **105**, 1529—1536.

The products of the action of precipitated malt diastase on granules of barley starch at the ordinary temperature, are found to be much more complex than previously supposed (cp. Brown and Morris, Chem. Soc. Trans., 1890, **57**, 510 ; 1901, **79**, 1085). Thus, conversion products possessing the constants of maltose were found to contain a dextrin of molecular weight exceeding 1500 and with R [cupric reducing power expressed as per cent. of maltose] =11·7 and $[\alpha]_{D\ 3\cdot9}=177\cdot6$; one or more dextrins of molecular weight similar to that of maltose ; maltose, and, after prolonged reaction, a small quantity of dextrose probably derived from the dextrins of low molecular weight (cp. Ling, this J., 1903, 1204). The amount of starch dissolved varies; as much as 80% was converted during a long period of digestion at 30° C.—L. E.

Determination of mannitol. Smit. *See* XXIII.

Manufacture of betaine salts [*from molasses, etc.*]. Eng. Pat. 2923. *See* XX.

XVIII.—FERMENTATION INDUSTRIES.

Yeast; Cultivation of pure —— *on the practical scale.* C. Engelhard. Z. ges. Brauw., 1914, **37**, 345—347.

The original Copenhagen apparatus is used, and the method differs from those commonly employed in that hot wort is run direct from the copper, under sterile conditions, into the apparatus without being boiled a second time prior to use; and after discharge of the yeast crop from the fermentation cylinder, the residue of yeast in the cylinder is used for pitching a fresh charge of wort. Since the wort employed for the cultivation is not boiled after it has left the copper, its composition is identical with that of the brewery wort. Two fermentation cylinders are used, so that one can be cleaned and repaired without interruption of the work. The method has been successfully and continuously employed for 8 years in a Swiss brewery.—L. E.

Enzymes of washed zymin and dried yeast (*Lebedeff*). *III. Peroxydase, catalase, invertase, and maltase.* A. Harden and S. S. Zilva. Biochem. J., 1914, **8**, 217—226. (See also this J., 1914, 658.)

Peroxydase. Fresh English brewery yeast gave the peroxydase reaction with *p*-phenylenediamine and hydrogen peroxide. The reaction was not given by yeast which had been dried for 17 hours at 37° C., or by dried Munich yeast (Schroder), but in both cases the dried yeast regained its peroxydase activity on washing. The washings inhibited the peroxydase activity of milk as well as that of yeast. The action of the inhibiting agent, which prevented the reaction in the case of dried yeast, increased in a higher proportion than that of the peroxydase as the amount of yeast was increased. Tyrosinase and oxydase could not be detected in any of the specimens of yeast. *Catalase.* The activity of the catalase of dried Munich yeast was not affected by washing. *Invertase and maltase.* The maltase-activity of zymin and dried Munich yeast was not affected by washing at ordinary temperature, but the invertase-activity was diminished. —A. S.

Micro-organisms (*lactic ferment*); *Lack of hereditary accommodation of* —— *in feebly nutritive media.* C. Richet. Comptes rend., 1914, **158**, 1749—1753.

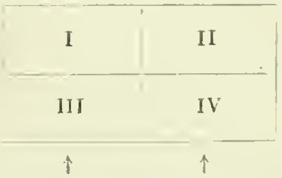
It has been shown previously that by cultivating the lactic ferment in presence of poisons (*e.g.*, thallium salts) a strain can be obtained which although less active than a normal strain in normal milk, is much more active in milk containing thallium. It is now shown that this accommodation does not take place in media deficient in food. When the ferment grows in milk diluted with water containing lactose a weakened strain results which is much less active than the normal form whether the conditions of nutrition are good or bad.—W. H. P.

Wort boiling; Chemistry of pressure ——. E. Moufang. J. Inst. Brew., 1914, **20**, 378—397.

Among the advantages claimed for the boiling of worts under pressure are, saving of about 33% of fuel and 5—10% of hops, better (more complete) "break" of the wort, cleaner fermentations, and as regards the beer, greater brilliance, improved fining capacity, increased stability and head-retaining power, and rounder and fuller flavour. The author studied the effect of superheating on various constituents of wort. Neutral sugar solutions are darkened and this is also true of worts; the effect is much intensified by alkalis but lessened by acids. The fermentability of maltose, lævulose and dextrose is somewhat diminished, whereas that of sucrose and dextrin is increased. The acidity of worts is increased whilst their content of proteins and phosphorus is diminished. Superheating promotes certain qualitative changes in the hop constituents which enhance the bitterness and acidity of the wort.—J. H. L.

Wort and beer; Colorimetric method for the determination of acids in ——. H. Lüers. Z. ges. Brauw., 1914, **37**, 334—337.

The method eliminates the disturbing influence of the colour of malt liquors during their titration with alkali in presence of phenolphthalein. Four similar tall cylindrical glass vessels, each of 50—100 c.c. capacity, are placed together, thus:—



I. contains distilled water, and II. a standard colour solution of some permanent dyestuff, of which the tint corresponds exactly with that of a 1/15-mol. solution of disodium phosphate treated with 5 c.c. of phenolphthalein solution (0·5 grm. of the solid in 500 c.c. of alcohol and 500 c.c. of water) per 50 c.c. III. and IV. contain each 50 c.c. of the liquid to be titrated, mixed respectively with 5 c.c. of the phenolphthalein solution and 5 c.c. of water. The liquid in III. is titrated with alkali (about the same volume being added to IV. also) until the same tint is observed on looking through the right and the left pairs of vessels.—J. H. L.

Beer; Torula producing a pine-apple flavour in ——. E. R. Moritz. J. Inst. Brew., 1914, **20**, 338—342.

Cases of the occurrence of a pine-apple odour on brewery fermentations, followed usually by a similar flavour in the beer, have been observed from time to time. The affection is, as a rule, first perceptible as a "beery" odour which becomes in turn reminiscent of pine-apple or peardrops, honey and finally raw sugar. A non-sporulating yeast, isolated from a sample of refrigerator wort was found to produce similar effects. This "pine-apple torula," cultivated in wort, forms cells 4—12μ by 2—3½ μ. Like many wild yeasts of the brewery, it is a large reproducer but a very small attenuator. The production of odour and of alcohol is practically the same at 65° as at 55° F. (18·3° and 12·8° C.) but reproduction is much greater at the higher temperature. Antiseptics in the proportions usual in brewery practice have little effect; hopping restricts its development somewhat and this is probably the reason why mild ales are more liable to be infected than pale ales. It assimilates dextrose more readily than other sugars and does not invert sucrose. When once the organism has a footing in a brewing little can be done to inhibit its action, and the best remedy is to ascertain and eliminate the sources of infection, which are most frequently stagnant grains in proximity to wort and fermentations, and malt dust and malt-house contamination.—J. H. L.

Wines; Investigations on the white —— of South Africa: an œnological study. H. T. Brown. J. Inst. Brew., 1914, 20, 345—375.

Statistics are given relating to the imports of wines from Cape Colony to the United Kingdom from 1857 to the present time. The value of the annual imports at present is £1000—£2000, representing only about 2% of the value prior to 1860, when the heavy preference given to Colonial as compared with foreign wines was discontinued. The wines formerly imported were mainly highly fortified products of the type of port and sherry. Of the light unfortified wines of to-day the red varieties are much more satisfactory and uniform in quality than the white wines, as the former require less skill in the making, and are much less sensitive to certain diseases. The white wines of the Cape are peculiarly liable to *casse* or turbidity, accompanied or preceded by an increase in the colour of the wine, a more or less pronounced bitter flavour, and a very characteristic earthy odour or *terroir*. The malady, which possesses the general character of *casse ferrique* (see Lagatu, this J., 1897, 751) is not of biological origin, but is conditioned by purely chemical changes. The essential conditions for its appearance are access of oxygen, the presence of iron salts which act as carriers of oxygen, and the presence of certain oxidisable substances of the wine, notably tannic acid. A mere trace of iron, such as may be extracted during filtration through asbestos or decolorisation with animal black, suffices, by alternate oxidation and reduction, to produce a large cumulative effect when the supply of free oxygen is not limited and sufficient time is given. The *casse* itself consists of a colloidal combination of iron with products derived from the limited oxidation of tannin and certain proteins, and it may be distinctly perceptible when amounting to only a few mgrms. per litre. At ordinary temperatures the whole of the oxidised products do not separate from a wine which has undergone *casse*, and a distinct improvement in the flavour and colour of the wine may be effected by chilling for some days at 31°—32° F. (0° C.) and filtering cold. Addition of sulphurous acid (potassium metabisulphite), even within the limits allowed by the Adulteration Act of the Union, 1913 (200 mgrms. per litre for dry wines, and 357 mgrms. for others), has a marked effect in preventing *casse* and in restoring faulty wines to their original state. Citric acid diminishes the tendency of a wine towards *casse*, but tartaric acid has little effect. Addition of tannin to white wines is deprecated, and in order to prevent its presence in more than a trace, it is advisable to effect a rapid separation of the juice from the skins and a judicious cutting off of the "press wine" from the bulk. Fining with isinglass or egg white, or better still, filtration, is preferable to the tannin-gelatin process of fining. Further means of guarding against *casse* are quick fermentation with selected yeasts and well controlled by attemperation, cold storage and maturation of the wine, and the avoidance of residual air in the bottles. Several tests are described by which the tendency of samples of wine to develop *casse* may be compared:—(1) Treatment with "10-vol." hydrogen peroxide at the rate of 10 c.c. per litre; most wines will show enhanced colour or turbidity within 6—7 hours, and faulty samples within a few minutes. (2) Treatment with 0·2 c.c. of a 2% solution of ferrous sulphate per 100 c.c.; a satisfactory sample may show no turbidity for 14 days. (3) Ten c.c. of the wine are treated with 0·5 c.c. of $N/10$ sodium hydroxide solution in such a manner that the latter sinks in the wine and forms a separate layer. At the junction of the two liquids, *i.e.*, at the zone of neutrality, there is a more or less purple ring below which is a zone varying in colour from straw yellow to a very dark sherry colour. The intensity of the colour of these two zones corresponds to the tendency of the wine to undergo *casse*. There appears to be no connection between the presence of oxydases in wine, and the *casse ferrique*. The grape contains, in quantities differing according to the variety, an oxydase (peroxydase) which occurs in the inner cells of the epidermis, and in the vascular bundles underlying the skin and those connecting the pips with the stalk. Freshly expressed grape juice contains no oxydase, but the oxydase reaction (with benzidine and hydrogen peroxide) appears when the juice has been in contact with the skins for a short time. Juice which contains a considerable quantity of oxydase has a tendency to become brown on exposure to air. This is particularly notable with the White French variety of grape which is specially rich in oxydases. The so-called "light" wines of S. Africa are much higher in alcoholic strength than the average European wines of a similar class, owing to the higher gravity and sugar content of the must before fermentation, dilution being forbidden by law. This in itself appears to favour *casse* in the white wines, and certainly detracts from their value as beverages for general table use. The author is convinced that a dilution of the must to about the gravity of the musts of the light European wines would tend to improve the character of the South African wines and that the prohibition of this dilution by law and of the addition of citric acid are directly detrimental to the quality of most of the wine produced there.—J. H. L.

Wine; Determination of lactic acid in —— by W. Möslinger's barium chloride method. W. I. Baragiola and O. Schuppli. Z. Unters. Nahr. Genussm., 1914, 27, 841—881.

The serious errors shown to be inherent in Möslinger's method are, to a great extent, eliminated in the following modified method:—A mixture of 25 c.c. of the wine and 25 c.c. of water is distilled to half its volume and then steam distilled until a total of 200 c.c. of distillate has passed over; the distilling flask is fitted with a special dephlegmating device (see von Babo and E. Mach, Kellerwirtschaft, 1910, 628). The distillation residue is rinsed into a dish with water, treated with 5 c.c. of a 10% solution of barium chloride, and neutralised with a hot saturated solution of barium hydroxide; if the presence of lactic anhydride is suspected, 2—4 c.c. of a cold saturated solution of barium hydroxide are now added, the whole is heated for 10 mins. on the water-bath, and made neutral, with hydrochloric acid, to azolitmin paper. The neutral solution is concentrated to 10—15 c.c., being kept neutral during evaporation; it is then rinsed with a small quantity of hot water into a graduated cylinder, made up to 25 c.c., cooled, and treated, whilst being vigorously shaken, with 95—96% alcohol. The solution is made up to 100 c.c. with 95—96% alcohol, left overnight, and again made up to 100 c.c. with alcohol, and filtered; 75 c.c. of the filtrate are treated with 25 c.c. of a 5% solution of sodium sulphate, shaken, left for about 15 mins., and filtered; 75 c.c. of this second filtrate are evaporated and incinerated in a platinum dish, the alkalinity of the ash then being determined. If the alkalinity corresponds to a c.c. of $N/1$ solution, the wine contains $(a \times 6{\cdot}4)$ grms. of lactic acid per litre. In the case of wines to which known quantities of lactic acid had been added, 84—100% of the added acid was found by the above method, whilst only 57—68% was found by Möslinger's original method.

XIXa.—FOODS.

Hardened [hydrogenated] fats; Suitability of —— for human food. K. B. Lehmann. Chem.-Zeit., 1914, 38, 798—799.

Commercial samples of hydrogenated arachis, sesamé and cottonseed oils contained from 0·07 to 6 mgrms. Ni per kilo. Feeding experiments with these fats were made upon animals and human beings for periods up to six months without any ill effects being felt or observed. —C. A. M.

Rice grains; Disintegration of —— by means of alkali. F. J. Warth and D. B. Darabsett. Agric. Research Inst., Bull. No. 38, 1914, pp. 1—8, with seven photographic plates.

The quality of rice grains, and the differences between various kinds of rice, may be demonstrated, to some extent, by their behaviour when immersed in alkali solution. The degree of attack, as shown by diffusion, disintegration and gelatinisation, is best observed when the grains are placed for 24 hours in potassium hydroxide solutions varying in strength from 1·0 to 1·25%. The tests must be made on the polished grains, and, provided that the outer coat of the grains has been removed, the effect of the alkali is independent of the extent of the polishing and is governed by the quality of the grain and the nature of the starch it contains. The method may also be used for distinguishing quality in paddy, but in the case of wheat grains the action of the alkali does not show the marked differences that it reveals with rices. (See also this J., 1914, 433.)—W. P. S.

Castor seeds; Detection of ——. G. D. Lander and J. J. Geake. Analyst, 1914, **39**, 292—295.

Active ricin is detected by incubating 2 grms. of the material with 40 c.c. of 0·9% salt solution for 1 hour at 37° C., allowing the mixture to stand overnight, and then centrifuging it for an hour at 3800 revolutions per min One c.c. of the clear liquid is made to form a layer ver about 0·1 c.c. of antiricin serum, and in the presence f ricin a zone developing after 12 hours into a precipitate s obtained. As a confirmatory test well-washed blood orpuscles suspended in physiological salt solution are reated with the extract. Agglutination is rapidly hown with the mixture consisting of 10% castor seed nd 90% linseed, but is less pronounced with smaller roportions of castor seed. Proof that ricin is the agglutinting agent is obtained by mixing equal quantities of ormal serum and antiricin serum with equal quantities of he extract from the seeds, and adding to each the same mount of the blood-corpuscle suspension. Inhibition of gglutination in the antiricin mixture indicates the presence f ricin.—C. A. M.

offee; On a new method of removing injurious substances from ——. J. Görbing. Z. öffentl. Chem., 1914, **20**, 202—216, 222—229.

ubstances having an injurious effect on certain ndividuals are produced when coffee berries are roasted, ut may be eliminated by coating the raw berries with ay and removing the coating subsequently from the asted berries. The clay removed from the berries ntains considerable quantities of reducing substances d fat.—W. P. S.

olouring matters; Influence of artificial organic —— on the enzymic hydrolysis of proteins. H. Damianovich and L. Guglialmelli. Rev. Gén. Mat. Col., 1914, **18**, 161—165.

ntinuing previous work (this J., 1911, 644) on the fluence of dyestuffs on the digestion of albumin by psin in an acid medium, the effect of varying concentrations of the dyestuffs was studied. Acid dyestuffs d a powerful inhibitive action even at great dilution, e effect of picric acid, for instance, being perceptible at a ncentration of only 0·0001%. The action increased th the concentration of the dyestuff and was always companied by a staining of the albumin; in some cases, r example with Ponceau 2R, Erythrosine, Chloramine llow, Congo Red, etc., a precipitate was produced. Basic dyestuffs were, in general, without action, but in some cases (*e.g.* Methylene Blue) had an accelerating effect in the more concentrated solutions. In similar experiments on the effect of dyestuffs on the digestion of casein by pancreatin in an alkaline medium, the results were, on the whole, with certain exceptions in the more dilute solutions, the reverse of those observed in the digestion of albumin by pepsin in an acid medium, *i.e.*, the basic dyestuffs exerted an inhibitive action and the acid dyestuffs were inactive.—A. S.

Patents.

Food products [pectinous substances]. H. Wade, London. From R. Douglas, Rochester, N.Y., U.S.A. Eng. Pat. 12,439, May 28, 1913.

Vegetable substances or fruits, preferably apples, are pressed in order to remove saccharine juices and the pulp is then extracted under pressure with hot water containing 0·1% of tartaric acid. The extract, after being evaporated to a syrupy consistence, forms a jelly when mixed with sugar and water.—W. P. S.

Flour, meal, offals, bran, grain, or like material; Treatment of ——. E. Samuelson, Banbury, Oxford, and J. Backhouse, Bootle, Lancs. Eng. Pat. 16,230, July 15, 1913.

The flour or other material is introduced into the lower part of a vertical chamber of circular cross-section provided with beaters attached to a rotating central shaft. The beaters cause the flour to rise in the chamber in the form of a cloud. A spray of liquid or liquid-laden air is introduced tangentially into the chamber, and the treated flour is discharged through an opening at the upper part. —W. P. S.

Pasteurised milk; Process for utilising the heat of ——. A. Domke. Ger. Pat. 273,388, May 14, 1913.

Before passing to the heat-interchanger in which it serves to preheat the cold milk, the hot pasteurised milk is led through a small apparatus in which it serves to pasteurise the cream.—A. S.

Buttermilk; Preparation of —— which can be preserved for a long time. R. Suwelack. Ger. Pat. 273,628, Jan. 30, 1913.

Fresh buttermilk is heated for some time at not below 85° C., with vigorous agitation, then rendered homogeneous by forcing it, under a pressure of about 250 atmospheres, through narrow tubes against a hard surface, and after being cooled and freed from air, is enclosed in air-tight vessels.—A. S.

Cocoa and chocolate substances; Art of roasting ——. F. E. F. Neumann, Wandsbek, Germany. Eng. Pat. 13,861, June 16, 1913.

See Fr. Pat. 463,325 of 1913; this J., 1914, 371.—T.F.B.

Protein compounds obtained from fish; Soluble —— and process of making the same. R. Adler, Assignor to Naamlooze Vennootschap Algem. Uitvinding Exploitatie Maatsch., Amsterdam. U.S. Pat. 1,101,513, June 23, 1914. Date of appl., Oct. 2, 1913.

See Eng. Pat. 7700 of 1913; this J., 1913, 957.—T. F. B.

XIXb.—WATER PURIFICATION; SANITATION.

Antiseptic properties; Relation between the structure and composition of organic compounds and their ——. K. Charitschkow. J. Russ. Phys.-Chem. Ges., 1914, 46, 70—76. Chem. Zentr., 1914, 1, 2196.

In experiments made with *Penicillium glaucum*, with the object of determining the suitability of various petroleum products for the impregnation of railway sleepers, it was found that Russian petroleum has no antiseptic properties, apart from those associated with small quantities of phenolic substances present therein. Naphthenic acids formed from petroleum by oxidation, and also their copper and zinc salts, are, on the other hand, powerful antiseptics. In the author's view only those organic compounds which are chemically active possess antiseptic properties, and the activity of the naphthenic acids is attributed to the presence of a five-membered ring in the molecule.—A. S.

Liver of sulphur ; Purchase and use of ——. J. Board Agric., 1914, **21**, 236—241.

Assuming that the fungicidal value of liver of sulphur is due to sulphur in the form of sulphides (hydrosulphide, sulphide, and polysulphide) (compare Foreman, this J., 1911, 150), the results of analyses in the Government Laboratory, of a large number of samples of different origin show that the quality of the commercial product varies very widely and that there is no connection between the price and the fungicidal value. The content of sulphide-sulphur decreases rapidly when liver of sulphur (solid or solution) is exposed to the air. The solid should preferably be packed in containers of small capacity (½ to 1 lb.) and the solution should either be prepared just before use or kept in full, tightly-corked bottles.—A. S.

Patents.

Furnaces [; Destructor ——]. T. W. Atterbury, New York, and P. W. Matthews, Wheeling, W. Va., U.S.A. Eng. Pat. 14,862, June 27, 1913. Under Int. Conv., July 5, 1912.

Four sets of trough-shaped grates are mounted on a horizontal drum, which is rotated at intervals, so that each grate occupies four positions successively. In the first position it receives a charge of refuse pushed in sideways by a ram, and hot combustion gases are passed through it to dry the refuse. The grate next comes into position two (the uppermost) and the dried refuse is burned. In the third position, air is passed through the grate to cool the ashes, and is subsequently used for burning the refuse in position two. On turning into position four (the lowermost) the cooled ashes are dropped on to a moving band conveyor.—W. H. C.

Water, vinegar, and other liquids ; Process for the sterilisation of —— *by means of bromine.* M. Riegel. Ger. Pat. 273,959, Sept. 17, 1913. Addition to Ger. Pat. 272,271.

After the treatment, as described in the chief patent (this J., 1914, 564), the bromine is removed by treatment with the calculated quantity of calcium sulphite or bisulphite.—A. S.

Boiler-feed water ; Process for purifying ——. N. Tikhomiroff. Ger. Pat. 274,351, Dec. 29, 1912.

The water after being mixed with the softening agent is forced through spraying nozzles disposed in a chamber through which the waste-gases from the boiler-furnace are passed. A series of such chambers is used, the water from each being collected in a receptacle or one compartment of a receptacle, whence it passes to a pump which forces it through the spraying nozzles in the preceding chamber or compartment.—A. S.

Water softening or purifying substance and process of obtaining same. P. de Brünn, Düsseldorf, Germany. Eng. Pat. 5783, March 8, 1913. Under Int. Conv., Sept. 27, 1912.

See Fr. Pat. 455,391 of 1913 ; this J., 1913, 958.—T. F. B.

Water ; Process for heating and purifying or softening ——. C. Erith, London. U.S. Pat. 1,099,433, June 9, 1914. Date of appl., March 20, 1911.

See Eng. Pat. 24,992 of 1910 ; this J., 1911, 570.—T. F. B.

Water ; Means for softening ——. H. J. Wheaton, Spondon. U.S. Pat. 1,100,803, June 23, 1914. Date of appl., Feb. 7, 1914.

See Eng. Pat. 4188 of 1913 ; this J., 1914, 216.—T. F. B.

Sewage ; Centrifugal apparatus for treating ——.
Bromet, F. Thorman, and H. C. Wood, Tadcaste
U.S. Pat. 1,098,554, June 2, 1914. Date of app
May 19, 1913.

839.—T. F. B.

XX.—ORGANIC PRODUCTS ; MEDICINAL SUBSTANCES ; ESSENTIAL OILS.

Ipecacuanha ; Alkaloids of ——. F. H. Carr and F.
Pyman. Chem. Soc. Trans., 1914, **105**, 1591—16
(See also this J., 1914, 610, and 1911, 1332.)

The three alkaloids emetine, cephaeline and psychotri
were obtained from the drug by Paul and Cownle
method, carefully purified, and the crystalline sa
characterised. The empirical formulæ are : emeti
$C_{29}H_{40}O_4N_2$; cephaeline $C_{28}H_{38}O_4N_2$; and psychotri
$C_{28}H_{36}O_4N_2$. Syntheses proved that psychotrine+H
cephaeline, and cephaeline+CH_2=emetine. When hyd
lysed by means of hydrochloric acid at 135°—140°
emetine and cephaeline both yielded the noremet
hydrochloride, $C_{25}H_{32}O_4N_2,2HCl$, melting at 240° C. w
decomposition. Emetine and cephaeline are second
tertiary, whilst psychotrine is a ditertiary base. Wh
emetine and benzoic anhydride were heated on the wa
bath benzoylemetine $C_{29}H_{39}O_4N_2.CO.C_6H_5$, was p
duced ; it crystallised from absolute alcohol in wh
prismatic needles, m. pt. 185°—186° C. On reducti
psychotrine yielded two isomeric bases, cephaeline a
*iso*cephaeline, the latter crystallising from alcohol
ether in clear plates, melting at 159°—160° C., and w
$[\alpha]_D = -71{\cdot}8°$ in chloroform. When treated with sodi
methyl sulphate and sodium amyloxide, the hydro
group of cephaeline was methylated with the format
of emetine. With methyl sulphate and sodium methoxi
on the other hand, methylation of the imino group t
place, principally with the formation of N-methylcephael
m. pt. 194°—195° C. and $[\alpha]_D = -48{\cdot}7°$ in chlorofo
N-methylemetine (hydrobromide m. pt 210°—230°
and a little emetine. The composition of the alkal
is therefore : psychotrine $C_{25}H_{26}(OCH_3)_3(OH)$
cephaeline $C_{25}H_{27}(OCH_3)_3(OH)(NH)N$; emet
$C_{25}H_{27}(OCH_3)_4(NH)N$. Emetine hydrochloride after
ing with ferric chloride solution gave a scarlet rubreme
hydrochloride soluble in chloroform, which when
dried had the composition, $C_{29}H_{32}O_4N_2,HCl$, and me
at 127°—128° C. with decomposition. After oxidi
with permanganate in acetone, emetine yielded a li
6.7-dimethoxy*iso*quinoline-1-carboxylic acid. The a
loids are considered to be derivatives of *iso*quinol
—F. Shd

Brucine ; Interaction between nitric acid and ——
presence of metallic nitrates. E. H. Rennie and A
Dawkins. Chem. Soc. Trans., 1914, **105**, 1487—149

The nitrates of sodium, potassium, cæsium, rubidi
and strontium accelerate the production of the rose
coloration due to the interaction of nitric acid and bru
the effect increasing with increasing concentration of
nitrate. The reaction is apparently due to the pres
of nitrous acid, as no colour is produced if urea is ad
to the nitric acid. The general results are similar to t
given by nitric acid and copper in the presence of met
nitrates (this J., 1908, 746 ; 1911, 751), but no retar
effects were observed as in experiments with copper.
—R. G.

Berberine and its determination. E. Richter. Arch. Pha
1914, **252**, 192—205.

The alcoholic extract of *Berberis* bark represe
4 grms. of the drug, or an equivalent amount of
tincture, is evaporated to dryness, dissolved in w
and 10 c.c. of 15% sodium hydroxide solution ad
The whole is shaken with 80 grms. of ether for 10

mins. and 1 grm. of powdered tragacanth added. 40 grms. of the ethereal solution are treated with 10 c.c. of $N/10$ solution of picrolonic acid (nitrophenylmethylisonitroso-pyrazolone), and the precipitate of berberine picrolonate collected, washed with a little ether and alcohol and dried at 110 C. The weight obtained multiplied by 0·561 gives the equivalent amount of berberine. (See this J., 1907, 1252.)—F. Shdn.

N-Demethylocodeine. O. Diels and E. Fischer. Ber.' 1914, **47,** 2043—2047.

odeine dissolved in acetone was treated at the ordinary emperature with the dimethyl ester of azodicarboxylic cid. The condensation product was warmed on the ater bath with $N/1$ hydrochloric acid and gave N-lemethylocodeine, $C_{17}H_{19}O_3N$, the dimethyl ester of ydrazodicarboxylic acid and formaldehyde. The codeine st the methyl group attached to the nitrogen. emethylocodeine crystallised from acetone in small exagonal leaflets m. pt. 185° C., gave a hydrochloride lecomposing at 314° C., and a diacetyl derivative rystallising from absolute alcohol in flat transparent rystals, m. pt. 176°—178° C.—F. Shdn.

aphnandra micrantha; Alkaloids of ——. F. L. Pyman. Chem. Soc. Trans., 1914, **105,** 1679—1687.

he bark of *Daphnandra micrantha* Benth., grown near risbane, contains over 6% of total alkaloids. Three ew alkaloids were isolated. Daphnandrine, $C_{36}H_{38}O_6N_2$, is e most abundant. It is dibasic, contains three methoxyl roups and one N-methyl group, and is non-phenolic. rystallised from chloroform it forms colourless needles, . pt. 280° C. and has $[a]_D = +474·7°$ for the dried base the same solvent. Micranthine, $C_{36}H_{32}O_6N_2$, is also on-phenolic, contains one methoxyl group and one methyl group and is dibasic. The base crystallises om chloroform in colourless needles, m. pt. 196° C. aphnoline, $C_{34}H_{34}O_6N_2$ or $C_{35}H_{36}O_6N_2$, is dibasic, and ntains a phenolic hydroxyl group, two methoxyl groups d one N-methyl group. After crystallising from cohol or chloroform it melts between 190° and 215° C. d has $[a]_D = +459°$ in chloroform.—F. Shdn.

arbaloin into β-barbaloin; New method of transforming ——. E. Léger. Comptes rend., 1914, **158,** 1903—1905.

hen barbaloin was heated to 100° C. with acetic hydride and sodium acetate, a penta-acetylbarbaloin as produced. After hydrolysing by means of alkali, mixture of barbaloin and β-barbaloin was obtained, om which the two substances were separated by means the insolubility of the former in chloroform and methyl cohol.—F. Shdn.

dinene from Daniella thurifera. W. Lenz. Ber., 1914, **47,** 1989—1991.

dark brown balsam obtained in E. Africa from *Daniella urifera* Benn. (*Leguminosae*) yielded about 23% of oil distillation with steam, leaving behind a soft resin. The was found to contain a considerable proportion of dinene.—F. Shdn.

ast; Curative action of autolysed —— against avian polyneuritis. E. A. Cooper. Biochem. J., 1914, **8,** 250—252.

e liquid obtained by autolysis of brewers' yeast, for ample for 36—48 hours at 35°—36° C., possesses as rked curative properties against avian polyneuritis the original yeast, and 10 times the minimum curing e has no toxic action. The liquid retains its curative wer for at least 8 weeks, and as air-dried yeast is still ive even after storage for 2 years, and can be autolysed er storing for 4 months, the method described is an xpensive one for preparing a non-toxic solution suitable the oral treatment of human beri-beri.—A. S.

Essential oils; Constituents of ——. Galbanum oil. Syntheses in the sesquiterpene and diterpene series. F. W. Semmler and K. G. Jonas. Ber., 1914, **47,** 2068—2082.

A specimen of galbanum oil with the following characters: b pt. 55°—195° C. at 15 mm, $n_D = 1·49395$ at 25 C., $a_D = +8°$ at 25° C., and sp. gr. 0·9353, was found to contain pinene, cadinene, nopinene, myrcene, a terpene derivative, $C_{10}H_{16}O$, and a new sesquiterpene alcohol, $C_{15}H_{26}O$. The terpene derivative boiled at 105°—115° C. at 15 mm., had the sp. gr. 0·951 at 20° C., $n_D = 1·4918$ and $a_D = +6°$; it appeared to be a readily enolisable ketone. The tertiary sesquiterpene alcohol, cadinol, boiled at 155°—165° C. at 15 mm., had the sp gr. 0·9720 at 20° C., $n_D = 1·50702$, and $a_D = +22°$ C. The characters of the acetate were: b. pt. 160°—170° C. at 9 mm., $n_D = 1·49870$ at 19° C., sp. gr. 0·9916 at 19° C., $a_D = +14°$ at 19° C. Cadinol was readily dehydrated by means of potassium bisulphate, etc., yielding a hydrocarbon, which gave cadinene dihydrochloride, m. pt. 117°—118° C., after treatment with hydrochloric acid. Cadinene regenerated from the dihydrochloride and that prepared by dehydrating cadinol were reduced by means of platinum and hydrogen and the products compared. Octahydro-α-camphorene (this J., 1913, 379) boiled at 183°—186° C. at 14 mm., had $n_D = 1·46001$, sp. gr. 0·8331 at 20° C., and was optically inactive. After myrcene had been polymerised by means of hydrochloric acid and the hydrochloric acid split off again, a bicyclic diterpene, iso-α-camphorene, was obtained, with the characters: b. pt. 193°—197° C. at 19 mm., $n_D = 1·50300$, sp. gr. 0·9029 at 21° C., and optically inactive. Reduction by means of platinum and hydrogen gave rise to a hexahydro-derivative. When heated in a sealed tube with anhydrous oxalic acid, linalool yielded α-camphorene, whilst citronellal gave an oxide, $C_{20}H_{34}O$. The latter boiled at 190°—200° C. at 17 mm., and had the sp. gr. 0·9193 at 20° C., $n_D = 1·49156$ and $a_D = +4°$. It was converted into a compound, $C_{20}H_{38}O$, by reduction with platinum and hydrogen. Cycloisoprenemyrcene (this J., 1913, 624) is monocyclic, for when reduced with platinum and hydrogen it yielded a hexahydro-derivative, $C_{15}H_{30}$, with the following characters: b. pt. 133°—135° C. at 15 mm., $n_D = 1·45497$, sp. gr. 0·8245 and optically inactive. When α- and β-phellandrene were heated with isoprene in a sealed tube, a bicyclic sesquiterpene was produced. Limonene and isoprene could be condensed to a monocyclic sesquiterpene by treatment with ethylsulphuric acid between —10° and —18° C. Pinene and sabinene when heated in a sealed tube with glacial acetic acid and sulphuric acid yielded a monocyclic sesquiterpene.
—F. Shdn.

Essential oils; Analysis of [determination of esters in] ——. Béhal. Bull. Soc. Chim., 1914, **15,** 306—308, 565—568.

A source of error in the determination of the esters in essential oils by saponification is due to the fact that in the presence of alcoholic alkali the esters are decomposed so as to give the ester of lowest molecular weight and liberate the alcohol of higher molecular weight. For instance menthyl formate in alcoholic potassium hydroxide gives ethyl formate and geraniol, and when benzyl benzoate is warmed with the same reagent the odour of ethyl benzoate is easily perceptible. Owing to the ready volatility of these lower esters, losses occur during the saponification which can be prevented by heating the mixture in a closed vessel in a water bath. Formic acid is present in many essential oils, particularly in Algerian geranium oil.—F. Shdn.

Essential oils; Vanillin hydrochloric acid reaction for ——. J. Cerdeiras. Pharm. Zentralb., 1914, 340. Perfum. and Essent. Oil Rec., 1914, **5,** 265.

A fresh solution of 0·5 grm. of vanillin in a little alcohol is made up to 100 grms. with hydrochloric acid of sp. gr. 1·10 at 15° C. One drop of the oil is added to 5 c.c. of the reagent, the whole shaken and allowed to stand for 15 mins. in the dark, when it is heated for 5 mins. in boiling water, cooled and shaken with chloroform. The colour reactions observed during these three operations can be compared with those produced by known oils. A table of the colorations obtained for a number of oils is given. —F. Shdn.

Shō-Gyū and Yu-Ju oils. K. Nagai. Perfum. and Essent. Oil Rec., 1914, 5, 244—249.

The Shō-Gyū tree, probably identical with the "black camphor" tree, grows to a height of 40—50 feet in continuous belts of forest at an altitude of 5000 to 6500 feet in Formosa. The wood is distilled locally and a yield of 1·3 to 3·0% of oil can be obtained. Several samples examined were colourless or light yellow and had the following characters: sp. gr. 0·900 to 1·031; optical rotation +7·75° to +34·45°; refractive index 1·4750 to 1·5023 at 20°—25° C.; soluble in an equal volume of 80% alcohol at 30° C.; acid value 0·1 to 0·76; ester value 0·0 to 2·4; total alcohol by acetylation (10 grms. oil, 10 grms. acetic anhydride, 2 grms. sodium acetate, 2 hrs. acetylation, 2 hrs. saponification) 13—40%. The following constituents were identified: formaldehyde in very small amount, sabinene, dipentene, a-terpinene, terpineol-4, geraniol, citronellol, safrol, eugenol, cadinene and linalool.

Yu-Ju oil is obtained from the so-called "oil-tree" indigenous to Southern Formosa, and is closely allied to camphor oil. In external form the tree is identical with *Cinnamomum camphora*, but the two can be readily distinguished by the odour of a shaving taken from the root. An average yield of 3—4% of essential oil can be obtained from the Yu-Ju tree. The oils examined were light yellow or golden in colour, although brown oils are occasionally met with. The characters are: sp. gr. 0·942 to 0·967 at 15° C.; optical rotation +18·8° to +30·8°; refractive index 1·4756 to 1·4856 at 20° C. The following constituents were identified: furfural in small quantity; a- and β-pinene; camphene; dipentene; cineol in considerable quantities; a-terpineol; safrol; eugenol, and a blue oil boiling between 275° and 290° C. A considerable quantity of camphor could be obtained by fractionating the oil and cooling, although this oil contains less camphor and more cineol than camphor oil.—F. Shdn.

Cymbopogon coloratus, Stapf; Oil of —— from Fiji. Bull. Imp. Inst., 1914, **12**, 48—50.

The leaves are stated (Bull. No. 6, 1913, Dept. Agric. Fiji) to yield about 0·35% of volatile oil, equivalent to about 29 lb. per acre. The oil has been examined by Goulding and Earl (Chem. Soc. Proc., 1914, 30, 10) who find that the principal odorous constituent is citral, 40%; it also contains geraniol, 23% in the free state and 10% as geranyl acetate. About 7·5% of terpenes are present, probably containing *l*-limonene, together with small amounts of free acetic acid and phenols; a solid tasteless and odourless phenol was isolated. A small consignment of the oil sold at 2d. per oz. in London (Jan. 1913), with Cochin lemongrass oil at 4¼d. per oz. and Ceylon citronella oil at 1s. 6½d. to 1s. 8d. per oz.—R. G. P.

Terpenes; Synthetic hydrocarbons allied to ——. W. N. Haworth and A. W. Fyfe. Chem. Soc. Trans., 1914, **105**, 1659—1671.

Certain ketones of the *cyclo*hexene series were condensed with ethyl sodiocyanoacetate, the acid thereby produced subjected to distillation in order to eliminate carbon dioxide, and the resulting ketone treated with magnesium methyl iodide. The ketones were converted into carbinols by the Grignard reaction and water eliminated from the latter by means of oxalic acid to obtain higher homologues of the terpenes. In this way two optically active hydrocarbons were prepared from *d*-1-methyl*cyclo*hexan-3-one, viz., *d*-1-methyl-3-dimethylvinyl-Δ^3-*cyclo*hexene and *d*-1-methyl-3-dimethylvinyl-Δ^2-*cyclo*hexene. The former boiled at 190°—191° C., had $n_D = 1·4793$, sp. gr. 0·8445 at 15°/4° C., and $[a]_D = +63·9°$. The latter hydrocarbon boiled at 192°—193° C., had $n_D = 1·4802$, sp. gr. 0·8531 at 15°/4° C., and $[a]_D = +54·8°$. 1-Dimethylvinyl-Δ^1 *cyclo*hexene was prepared by a similar series of reactions and had the characters: b. pt. 172°—173° C., $n_D = 1·4854$, and sp. gr. 0·8537 at 20°/4° C.—F, Shdn.

Thujone and thujamenthone. The direct conversion of one into the other. M. Godchot. Comptes rend., 1914, **158**, 1807—1808.

Thujone in the presence of hydrogen and nickel at 175°—180° C. is readily transformed into thujamenthone. The trimethylene ring under these conditions is readily reduced and broken, while the cyclopentane ring remains quite stable.—W. H. P.

Quinol; Colour reaction of —— in the solid state. Maldiney. Comptes rend., 1914, **158**, 1782—1783.

Solid quinol and potassium carbonate rubbed togethe give a chracteristic deep blue coloration. Sodium carbonate gives only a dirty mauve colour after long trituration, and ammonium and lithium carbonates have nc effect. Water destroys the colour, giving a yellow solution; alcohol and ammonia have the same effect. Ethe gradually destroys the colour without dissolving th product while chloroform and benzene have no action No other photographic developer has been found t resemble quinol in this respect.—W. H. P.

Isoprene; Physical constants of ——. C. Harries. Ber 1914, **47**, 1999—2003.

Two preparations of synthetical isoprene obtaine respectively, from the Elberfelde Farbenfabrik (A) and tl Badische Anilin- und Sodafabrik (B) after careful fractiontion were practically identical in boiling-point, specil gravity and elementary composition. The optical co stants, however, showed marked differences, from whi it is concluded that the specimen (B) either contain impurities or else consisted of a physically isomeric isopren The following constants are quoted for pure isopren b.pt. 33·75—34·0° C. at 762 mm.; $D_4^{16·5} = 0·6867$; $n_d^{16·5}$ 1·42617.—J. R.

Erythrene; New method of preparing —— from derivati of ethyl ether. J. Ostromysslenski and S. Kielbasins J. Russ. Phys.-Chem. Ges., 1914, **46**, 123—133. Che Zentr., 1914, **1**, 2155.

Monochloroethyl ether, $CH_3.CH(Cl).O.C_2H_5$, b. 92°—95° C., gives yields of up to 20% of erythrene wl heated to 350° C. in presence of alumina or barium chlori The catalyst, however, soon becomes inactive, owing the deposition of reaction products thereon. Sim results are obtained with acetal, $CH_3.CH(OC_2H_5).O.C_2$ and with this compound, in presence of alumina, a yi of up to 16% of erythrene can be obtained at the ordin temperature. The yield is not affected by the nat of the containing vessel or by diminishing the pressu —A. S

Methyl alcohol; Thermal decomposition of ——. W Bone and H. Davies. Chem. Soc. Trans., 1914, 1 1691—1696.

After heating for 10 mins. to 650° C. the vapour of me alcohol was converted into a mixture of carbon monox methane and hydrogen. During the decomposition carbon was deposited, nor could either acetylene ethylene be detected in the products. At 1000° C. decomposition was almost instantaneous without deposition of carbon or formation of acetylene or ethyl The gaseous products consisted principally of ca monoxide and hydrogen with a little methane and a t of carbon dioxide.—F. Shdn.

Patents.

6-*Hydroxy-2-piperonylquinoline-4-carboxylic acid; M facture of ——.* Chem. Fabr. auf Actien (verm Schering), Berlin. Eng. Pat. 15,482, July 4, Under Int. Conv., July 8, 1912. Addition to Eng. 15,481 of 1913.

An alcoholic solution of *p*-aminophenol is boiled an alcoholic solution of piperonal and pyroracemic The precipitated 6-hydroxy-2-piperonylquinoline- boxylic acid is purified through its sodium salt.—F. S *liphatic hydrocarbons from poly-methylenes or mixtures containing the same ; Manufacture of* ——. F. Sommer, Vienna. Eng. Pat 19,972, Sept. 1, 1913. Under Int. Conv., Sept. 24, 1912.

ON-SATURATED hydiocarbons are produced by dis- illation by the "cracking" process from polymethylenes r mixtures containing the same, and are then converted ito saturated aliphatic hydrocarbons by reduction.
—F. Shdn.

atty acids containing arsenic or phosphorus ; Process for producing iron salts of ——. F. Heinemann, Berlin. Eng. Pat. 29,741, Dec. 24, 1913. Under Int. Conv., Jan. 2, 1913. Addition to Eng. Pat. 18,732 of 1912, dated Nov. 29, 1911 (this J., 1913, 109).

ATTY acids containing arsenic or phosphorus, obtained treating fatty acids of the acetylene series with tri- logen derivatives of arsenic or phosphorus, are con- rted into iron salts by treating them or their salts th solutions of basic or neutral iron salts. For instance loro-arsenobehenolic acid dissolved in methyl alcohol neutralised with alcoholic soda-lye and mixed with an oholic solution of ferric chloride. Or the alcoholic ution of the acid may be added to a solution of iron tate or *liquor ferri oxychlorati* (German Pharmacopœia) ed with alcohol. The resulting iron salts are reddish wn powders insoluble in water or alcohol.—F. Shdn.

rapeutical agents in the treatment of tuberculosis and yphilis ; Process of manufacturing compounds suitable s ——. Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. Eng. Pat. 1837, an. 23, 1914. Under Int. Conv., Jan. 24, 1913.

IPOUNDS for use in treating tuberculosis and syphilis are luced by treating gold cyanide with a salt of an organic , particularly 1-phenyl-2.3-dimethyl-4-amino-5-pyrazo- or its alkyl derivatives. By this means the gold nide is protected from immediate reduction.—T. F. B.

ine salts ; Manufacture of ——. Act.-Ges. f. Anilin- br., Treptow, Germany. Eng. Pat. 2923, Feb. 4, 914. Under Int. Conv., Oct. 16, 1913. Addition to ng. Pat. 2813 of 1914, date of appl., May 7, 1913 (see is J., 1914, 658).

ASSES, exhausted molasses, or other residue from the sugar factory is rendered feebly acid with hydrochloric and then evaporated in a vacuum at a temperature naterially above 60° C. until crystals begin to separate. ffect a more rapid separation, the evaporated solution be mixed with a further quantity of concentrated ochloric acid, after which the mass is cooled. The ion obtained in this way is free from humic sub- es, and deposits betaine hydrochloride mixed chiefly inorganic salts.—T. F. B.

s of phenol homologues halogenised in the side chain ; cess for the preparation of ——. Dr. Schmitz und Ges. m. b. H., Düsseldorf, Germany. Eng. Pat. 3, Feb. 5, 1914. Under Int. Conv., April 10, 1913.

GENS can be introduced into the side chain of esters enol homologues by treating the esters with halogens eir equivalent in presence of light, preferably from ce of light rich in ultra-violet rays, and at the ordinary rature or below 100° C. The esters may be dissolved rbon tetrachloride or other suitable solvent. In cases it is advisable to use a halogen carrier *ple :* 10·2 kilos. of chlorine are introduced into a on of 18 kilos. of *o*-cresol carbonate in carbon hloride, under the influence of rays from a mercury- r lamp ; the temperature is kept at about 25°—30° C. loro-*o*-cresol carbonate is obtained in the form oil. By carrying out the chlorination of the solid carbonate in presence of a small quantity of phos- pentachloride, ω-trichloro-*o*-cresol carbonate is ed.—T. F. B.

Mercury ; A preparation of —— *for therapeutic purposes.* Dr. Bayer és Tarsa, Budapest. Eng. Pat. 11,392, May 14, 1913. Under Int. Conv., June 28, 1912.

See Ger. Pats. 267,411 and 267,412 of 1912 ; this J., 1914, 220. The products may be dissolved in alkali.—T. F. B.

Aromatic mercury compounds ; Manufacture of ——. Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. Eng. Pat. 2314, Jan. 28, 1914. Under Int. Conv., Jan. 29, 1913.

See Ger. Pat. 272,289 of 1913 ; this J., 1914, 568.—T. F. B.

Propylene from acetylene and methane ; Production of ——. A. Heinemann, London. Eng. Pat. 12,365, May 27, 1913.

See Fr. Pat. 458,397 of 1913 ; this J., 1913, 1086.—T. F. B.

Isoprene ; Process for manufacturing synthetic ——. C. K. F. L. Gross, Christiania. U.S. Pat. 1,099,498, June 9, 1914. Date of appl., June 12, 1913.

See Fr. Pat. 459,988 of 1913 ; this J., 1913, 1129.—T. F. B.

Glycerine ; Process for the synthetic production of ——. A. Heinemann, London. Eng. Pat. 12,366, May 27, 1913.

See Fr. Pat. 458,398 of 1913 ; this J., 1913, 1086.—T. F. B.

Esters and ethers of ethylidene glycol and vinyl alcohol ; Manufacture of ——. Chem. Fabr. Griesheim-Elektron, Frankfort on Maine, Germany. Eng. Pat. 14,246, June 19, 1913. Under Int. Conv., June 21, 1912.

See U.S. Pat. 1,084,581 of 1914 ; this J., 1914, 219.—T.F.B.

Bismuth salt of gallocarboxylic acid ; Manufacture of the ——. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 16,715, July 21, 1913.

See Ger. Pat. 268,932 of 1912 ; this J., 1914, 277.—T. F. B.

Compounds containing residues of sulphophenol-ortho-carboxylic acids or their transformation products ; Process for producing ——. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 22,854, Oct. 9, 1913.

See Fr. Pat. 466,236 of 1913 ; this J. 1914, 637.—T. F. B.

Diaryl ethers ; Process for the formation of ——. L. Ostermann, Hamburg, Germany. U.S. Pat. 1,099,761, June 9, 1914. Date of appl., May 21, 1913.

See Eng. Pat. 9797 of 1913 ; this J., 1914, 102.—T. F. B.

Polyarseno compounds and process of making same. P. Ehrlich and A. Bertheim, Frankfort, Assignors to Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. U.S. Pat. 1,100,720, June 23, 1914. Date of appl., July 16, 1913.

See Eng. Pat. 14,409 of 1913 ; this J., 1913, 1030.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Quinol ; Modification of the developing power of —— *by introduction of substituents into the aromatic nucleus.* A. and L. Lumière and A. Seyewetz. Bull. Soc. Franç. Phot., 1914, 5, 181—184.

The introduction of halogen groups into the quinol nucleus results in an increase of developing power both in caustic alkali and in alkali carbonate solution ; bromine is more active in this respect than chlorine. Similarly the methyl group increases the developing power. On the other hand, the introduction of nitro or sulphonic groups causes a considerable decrease of developing power, dinitroquinol possessing no developing properties. When a halogen group and a sulphonic group are present together in the quinol nucleus, products are obtained which are more active than quinolsulphonic acid but less active than quinol itself, whatever may be the relative positions of the substituent groups.—T. F. B.

Quinone and sodium sulphite. J Pinnow. J. prakt. Chem., 1914, **89**, 536—546.

The chief product of the reaction between quinone and neutral sodium sulphite is quinolmonosulphonate of sodium: small quantities of quinol and hydroxyquinone or their derivatives are also formed. The velocity of these reactions is very great, and they do not appear to be connected with the gradual increase of colour of the sulphite-quinone solution. A partial reaction takes place between quinone and quinolmonosulphonate, with the formation of quinonesulphonate and quinol; the quinonesulphonate reacts with sulphite to produce quinoldisulphonate. The formation of quinonesulphonate and quinoldisulphonate can be promoted by adding acetic acid to the quinone solution or by increasing the concentration of the sulphite. Only very small amounts of sulphuric acid are formed during the reaction between quinone and neutral sulphite (see also this J., 1913, 214, 451; 1914, 161).—T. F. B.

Colour reaction of quinol in the solid state. Maldiney. *See* XX.

XXII.—EXPLOSIVES ; MATCHES.

Explosion of nitroglycerin; Circumstances attending an —— which occurred in a cordite stove at the factory of Messrs. Curtis's and Harvey, Ltd., at Cliffe, Kent, on April 29, 1914. Major A. Coningham, H.M. Inspector of Explosives. [Cd. 7453].

The building in which the explosion occurred was an empty cordite stove with three brick walls and a framework of wood in front. The inner side of the framework was lined with matchboarding, and the outer with corrugated iron sheets. The interior of the compartment was lined throughout with sheets of zinc soldered together. There was a space of about 4 ins. between the matchboard lining and the corrugated iron sheets. A workman, who lost his life, was engaged in removing the corrugated iron sheets from the front of the building. The wooden moulding at the top of the corrugated iron sheets had first to be removed, and the asphalt on the platform then chipped from the cement for about 2 ins., so as to enable the sheets to be taken away. Whilst doing this the chisel must have struck some nitroglycerin which exploded, and communicated the explosion to a small accumulation of nitroglycerin, probably ½ lb. to 2 lb., which had collected on the floor quartering and in the spaces between this and the corrugations of the galvanised iron sheets. During the process of drying cordite acetone vapour, carrying nitroglycerin, must have found its way through some small crack, or hole, in the zinc lining of the stove, and condensed on the cold surface of the corrugated iron sheets. The acetone would then evaporate, leaving nitroglycerin to trickle down, and, in the course of time, accumulate at the bottom of the iron sheets. Twenty-six such stoves had previously been dealt with in a similar manner, but in no case had any nitroglycerin been found in the hollow space of the wall. It is considered that it would be well, in the future, if, when repairs or alterations have to be carried out on the wall of a cordite stove of this nature, to deal with it as if there was an accumulation of nitroglycerin at the bottom of the space between the lining and the outer sheeting of the wall. In some cases the nitroglycerin might be dissolved and floated off by pouring, or injecting, acetone into the space, but the disadvantage of this method would be that the acetone, evaporating off, would leave the nitroglycerin deposited somewhere else. A preferable method would be to destroy the nitroglycerin *in situ* by an alcoholic solution of sodium hydroxide. There has been a tendency in recent years to avoid, as far as possible, the use of separate linings in building of this nature, and, in the modern stoves erected by the company, this has been effected by a facing of neat cement on the walls.—G. W. McD.

Fulminic and hydrazoic acids; New salts of —— an the explosive properties of fulminates and azides. L Wöhler and F. Martin. Z. angew. Chem., 1914, 27 335—336.

Anhydrous fulminates of K, Ca, Sr, Ba, Mn^{II}, Zn, Te and Cd have been prepared by treating mercury or silve fulminate with the requisite amalgam under methyl alcoho and precipitating the salt by means of ether. The highl explosive cuprous salt was obtained in aqueous solution it explodes with a sharp report, like all the fulminate with the exception of the manganese and mercury salt The alkali and alkaline earth salts are sensitive to moistu and to carbon dioxide. New azides of Mn^{II}, Zn, ar Co^{II} were obtained from the carbonates and ethereal az imide; the cobaltous salt contains water; all these azid are hygroscopic and readily hydrolysed. The cobalto salt is most sensitive to friction, but the manganese s detonates sharply. The initial explosive action of t fulminates and azides was compared by observing t amount of inflammable matter necessary for detonatio the fulminates were placed in the following order, Ag, C Cu^{I}, Tl, Hg^{II}, and the azides, Cd, Ag, Pb, Cu^{I}, Hg^{I}, T The sensitiveness to shock per unit of striking surface all the fulminates and azides was measured; when t thickness of the mass of substance tested was increas the sensitiveness to shock diminished in the case of the fulminates and the azides of Tl, Zn, Mn, and Cu^{I} increased with the azides of Pb, Ag, and Hg^{I}, and remai unchanged with cadmium azide. It thus appears that measurement of the sensitiveness to shock of only thickness of substance can give quite an erroneous indi tion of its character. The temperature of detonation of salts were also measured; in this respect thalleus fulm ate is the most sensitive (detonation at 110°) followed the fulminates of Hg^{II}, Ag, Cu^{I}, Cd, and Mn; the alkali earth and alkali salts begin with Ca (195°) followed Sr, Ba, Na, and K (237°). The azides are placed in following order:—Co (148°), Ba, Ca, Sr, (169°), Cu^{I}, Mn, Hg^{I}, Zn, Cd, Ag, Tl, Pb (327° C.).—T. F. B.

Explosives; Production of —— in the United States du 1912. A. H. Fay. U.S. Bureau of Mines. Techn Paper 69.

The total production of explosives in the United St during 1912, according to the figures compiled, 489,393,131 pounds, or 244,696 short tons. This duction is segregated as follows:—Black pow 230,233,369 pounds; "high" explosives (dyna nitroglycerin, dynalite, guncotton, etc.) other than missible explosives, 234,469,492 pounds; and permis explosives, 24,630,270 pounds. The total productio tabulated by States and by kinds of explosives. An table shows the total output of coal, with the correspon amount of explosives used in its production. The am of coal produced per pound of explosive varied from ton in the group represented by Arkansas, Oklahoma Texas to 5·82 tons in Maryland and Virginia: 133 were killed in coal mines by explosives during 1912 134 in 1911. In 1902 11,300 lb. of permissible explo were used in coal mining, whereas in 1912 the qua so used was 18,150,618 lb. The total amount of e sives used for the production of coal in 1912 was 2[illegible]6,14 lb. The use of permissible explosives in coal minin had gratifying results, and few, if any, serious acci can be attributed directly to their use. In 1912 three-fourths of the permissible explosives manufac were used for coal mining. The reports of manufact of fireworks and of ammunition are not included.

PATENTS.

Fuse compositions containing phosphorus; Manufacture of ——. Deutsche Waffen- und Munitionsfabriken. Ger. Pat. 274,000, Nov. 29, 1912.

THE phosphorus is mixed with a binding medium and with water, spirit, oil or the like, so as to form a viscous mass capable of drying like a paint. This is applied either to the inner surface of the cap or the like which is to receive the fuse composition, to the outer surface of the fuse composition, or to the inner side of a layer used as a cover for the fuse composition; or it may be rolled out into a sheet and itself used as a covering layer.—A. S.

Gunpowder; Process of preparing progressive ——. W. Eberlein, Brunswick, Germany. U.S. Pat. 1,098,237, May 26, 1914. Date of appl., Dec. 15, 1911.

SEE Fr. Pat. 437,714 of 1911; this J., 1912, 558.—T. F. B.

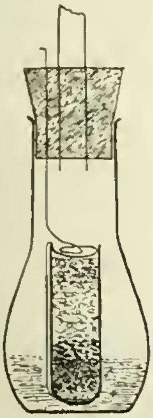
XXIII.—ANALYTICAL PROCESSES.

Platinum ware; Thermoelectric method for the determination of the purity of ——. G. K. Burgess and P. D. Sale. J. Washington Acad. Sci., 1914, **4**, 282—288.

THE index of purity is the thermoelectric force of the platinum ware against pure platinum at a known temperature. The most common impurity is iridium and all other metals usually associated with platinum affect the E.M.F. in the same direction as iridium. It is possible therefore for many purposes to represent the impurity as if it were all iridium. If a crucible is being tested two fine pieces of Heraeus normal thermoelement platinum are arc-soldered to it at opposite sides of the rim. They are then connected through a millivoltmeter. One is heated by a small flame and the other kept cool by an air blast. The temperature of the hot junction is measured on the same millivoltmeter by means of a platinum-rhodium thermocouple wire soldered near the same point. A commutator in the voltmeter circuit enables readings o be made for the temperature and then immediately for he E.M.F. of pure platinum against the alloy. By comparison with standard data the percentage of iridium equivalent to the impurity may be obtained.—W. H. P.

Fat extractor. G A. Stokes. Analyst, 1914, **39**, 295.

THE material to be extracted is placed in a fat-free paper himble, which is attached to the cork of the flask by means of a wire (see fig.). Above the material is placed otton-wool, which is held down by a spring bent in the ire. After extraction has proceeded for some time the wire is raised so as bring the thimble into the neck of the flask, where the extraction is completed.—C. A. M.



Platinum; Detection of —— *by means of stannous chloride.* E. Langstein and P. H. Prausnitz. Chem.-Zeit., 1914, **38**, 802.

STANNOUS chloride gives a blood-red coloration (gold-brown in very dilute solutions) with solutions of platinum chloride, and the colouring matter can be extracted with ether (Wöhler, Chem.-Zeit., 1907, 938). The test is very sensitive and is not given by iridium, palladium, gold or iron. Humic substances, however, and filter paper give similar reactions after treatment with *aqua regia*, and the test is only conclusive of platinum, when the filter paper has been completely incinerated and when any humic substances present have been destroyed (*e.g.* by fusion with pyrosulphate) prior to extraction with *aqua regia*. —C. A. M.

Mannitol; The methods for the quantitative determination of ——. J. Smit. Z. anal. Chem., 1914, **53**, 473—490.

THE various methods described for the determination of mannitol are reviewed. The following new method is recommended: To 50 c.c. of the solution contained in a 100 c.c. stoppered bottle, 25 c.c. of $4N$-sodium hydroxide and 25 c.c. of copper sulphate solution containing 125 grms. of the hydrated salt per litre are added, the whole is shaken well for a few seconds only and allowed to settle during 12 hours at the ordinary temperature. 25 c.c. of the clear liquid are withdrawn, treated with 10 c.c. of 30% potassium iodide solution and 10 c.c. of 25% sulphuric acid, and titrated with $N/10$-sodium thiosulphate. The quantity of mannitol corresponding to the number of c.c. of thiosulphate used is ascertained from the following table:—

$N/10$ $Na_2S_2O_3$ used per 25 c.c. of solution.	Mannitol in 100 c.c. of solution.	$N/10$ $Na_2S_2O_3$ used per 25 c.c. of solution.	Mannitol in 100 c.c. of solution.	$N/10$ $Na_2S_2O_3$ used per 25 c.c. of solution.	Mannitol in 100 c.c. of solution.
c.c.	mgrms.	c.c.	mgrms.	c.c.	mgrms.
0·25	0·0	9	310·7	20	659·7
0·5	8·3	10	344·4	21	691·9
1·0	27·4	11	378·1	22	724·1
1·5	47·8	12	410·8	23	756·6
2·0	68·0	13	441·6	24	789·6
2·5	88·0	14	472·4	25	822·6
3·0	107·1	15	503·1	26	855·6
4·0	142·8	16	534·4	27	888·6
5	176·7	17	565·6	28	930·9
6	210·0	18	596·9	29	992·4
7	243·3	19	628·1	29 1	1000
8	277·0				

Before applying the method it is necessary to remove any ammonium compounds, amino-acids, sugars, hydroxy-acids, or polyhydric alcohols which may be present.—J. R.

Colour reactions of organic compounds with trichloroacetic acid [and tetranitromethane]. K. Charitschkow. J. Russ. Phys.-Chem. Ges., 1914, **46**, 76—78. Chem. Zentr., 1914, **1**, 2202—2203.

TRICHLOROACETIC acid and tetranitromethane, which give colour reactions with cholesterol, give analogous reactions with a large number of compounds having a double linkage in the molecule, especially cyclic compounds. Colorations are obtained, for instance, with crude petroleum, solar oil, turpentine, menthene, terebenthene, phenanthrene, mesitylene (?), rosin, rosin oil, and oleic acid. Benzene hydrocarbons and low-boiling unsaturated compounds of the aliphatic series do not give colorations.—A. S.

Air; Apparatus for ascertaining the degree of purity of ——. J. C. y Leon, Madrid. U.S. Pat. 1,101,400, June 23, 1914. Date of appl., Feb. 13, 1913.

See Eng. Pat. 4141 of 1913; this J., 1913, 961.—T. F. B.

XXIV.—MISCELLANEOUS ABSTRACTS.

Trituration; Reactions by ——. L. H. Parker. Chem. Soc. Trans., 1914, **105**, 1504—1516.

Carefully dried mixtures of mercuric chloride and potassium iodide, lead nitrate and potassium iodide, lead chloride and potassium iodide, potassium bichromate and silver nitrate, copper sulphate and potassium ferrocyanide, lead acetate and potassium bichromate, and sodium carbonate and barium sulphate were triturated by means of a mortar and pestle contained in a closed desiccator. Interaction took place on trituration in every case, the results confirming those of Perman (Chem. News, 1903, **88**, 197; this J., 1907, 759), who found that dry salts may be left in contact without interaction, but that grinding frequently caused reaction to take place. It seems probable that interaction is caused by fusion of the salts due to trituration.—R. G. P.

Tin selenides; Thermo-electric power of ——. H. Pélabon. Comptes rend., 1914, **158**, 1897—1900.

SnSe forms a couple with platinum in which the current goes from the platinum towards the selenide across the hot junction. With temperatures of 0° and 100° C., the potential difference is —0·033 volt, and for temperatures of 0° and 580° C. it is —0·2 volt. $SnSe_2$ gives values of the same magnitude but of opposite sign up to 600° C. —F. Shdn.

Inositol; Synthesis of natural ——. H. Wieland and R. S. Wishart. Ber., 1914, **47**, 2082—2085.

A fairly good yield of inositol is obtained by hydrogenating hexahydroxybenzene suspended in water in presence of palladium black, at 50°—55°C.—L. E.

Methyl-glucosides; Structures of the two ——, and note on a third. E. Fischer. Ber., 1914, **47**, 1980—1989.

Nef's suggestion (see this J., 1914, 366) that α- and β-methyl-glucosides are structural- and not stereoisomerides is contested. A third isomeride, obtained as a syrup during the preparation of the other two, is described. This substance, or possible mixture of stereoisomerides, "γ-methyl-glucoside," was purified by distillation under reduced pressure. It differs from the isomeric crystalline substances in its behaviour towards emulsin, the yeast enzymes and dilute acids: the last-named agents effect its hydrolysis with extreme ease, this property being probably connected with the structure of the lactone ring.—J. R.

Oxidation processes; Mechanism of ——. III. [Determination of saligenin.] H. Wieland. Ber., 1914, **47**, 2085—2111.

In continuation of previous work (this J., 1913, 1132) evidence is brought forward to show that in the three aldehyde reactions which are accelerated by unboiled milk, viz., conversion of two mols. of aldehyde into one each of acid and alcohol, oxidation to the acid by molecular oxygen, and oxidation by methylene blue, with reduction of the latter to its leuco-compound, the acceleration is not due to three distinct enzymes, namely a mutase, an oxydase, and a reductase respectively, but to a single enzyme, which is a dehydrase. In the conversion of two mols. of aldehyde into one each of acid and alcohol, it is considered that 1 mol. of the aldehyde is converted into the hydrate, and this is then dehydrogenated under the catalytic influence of the dehydrase, a second mol. of the aldehyde, in its anhydride form, acting as hydrogen-acceptor: $R.CH(OH)_2+R.CH:O\rightarrow R.CO.OH+R.CH_2OH$.

It is shown incidentally that if saligenin in 0·4% aqueous solution be treated with a slight excess of 0·2—0·3*N* bromine solution, and after 20 seconds a few drops o potassium iodide solution be added, and the liberated iodine titrated with *N*/10 thiosulphate, although tribromophenol is formed in addition to dibromosaligenin, th results are quite concordant, a constant quantity of 5·3 equivalents Br being consumed per mol. of saligenin, s that the reaction can be used for quantitative purposes —A. S.

Book Received.

Journal of the Institution of Petroleum Technologists and Record of Transactions. Vol. 1 Part 1. Published by the Institution, 17, Gracechurc Street, London, E.C. Price 5s.

The first number of this Journal occupies 94 pages $8\frac{3}{8}$ by $5\frac{3}{8}$ ins.; following the official and editorial notice is an account of the Inaugural Meeting held on March 3rd 1914, containing the address by the President (Sir Boverto Redwood, Bart.), and papers by Sir Thomas Holland Mr. E. H. C. Craig, and Prof. V. B. Lewes. The last par of the volume contains the Memorandum and Articles c Association, By-laws and Regulations, and a list c Honorary Members, Members, Associate Member Students, and Associates.

MR. ARTHUR CAREY IN THE CHAIR.

THE CATALYTIC REDUCTION OF OLEIC ACID AND COTTONSEED OIL BY MEANS OF HYDROGEN IN PRESENCE OF FINELY DIVIDED NICKEL.

BY T. W. A. SHAW, M.SC.

In recent years several patents have been taken out for the reduction of unsaturated oils by hydrogen in the presence of metal catalysts (chiefly nickel). Very little has, however, been published as to quantitative yield, exact conditions, etc. The following experiments were undertaken to determine the yield, under definite conditions, in the reduction of :—

(a) Oleic acid vapour in a stream of hydrogen under reduced pressure.

(b) Liquid oleic acid by hydrogen under various high pressures.

(c) Cottonseed oil by hydrogen under various high ressures.

The experiments on oleic acid vapour were suggested y the method of reduction (*i.e.*, in the vapour state) nployed by Sabatier and Senderens.

As oleic acid on distillation at ordinary pressure decomoses, the whole process has to be carried out under duced pressure. To this end the following apparatus as devised and used. (Fig. 1.)

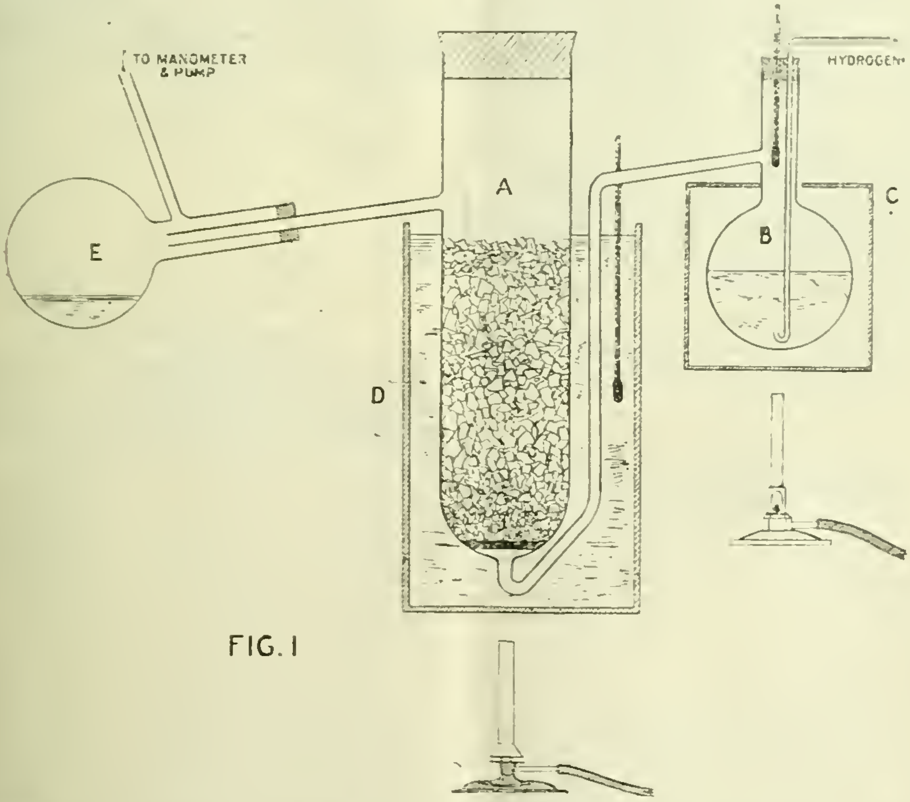

FIG. 1

A is a glass tower containing the catalyst. Its diameter is about 5·5 cms. and the length of the catalytic column is about 30 cms.

The catalyst was made in the following manner: Pumice stone broken into pieces about as large as a pea, and sifted so as to remove from it any fine dust, was placed in a Buchner funnel connected with a filter pump, and a strong solution of nickel nitrate was slowly drawn through it several times until it was practically all absorbed. This solution was generally made by dissolving about 200 grms. of nickel nitrate in its own weight of water. When the soaking was complete the pumice was placed in a muffle furnace and heated to a dull red heat, thereby converting the nitrate into oxide. The pumice with its coating of oxide was again soaked in the nitrate solution and ignited, so as to ensure a large quantity of catalyst. This was then placed in the tower, A, and reduced in a current of hydrogen at a temperature of about 300° C. The heating was effected by immersing the tower in a tall copper cylindrical oil-bath, D, which contained an oil which could be readily heated up to 350° C. to 400° C. if such a temperature were required. The reduction is complete in about two to three hours and its completion is shown by no more moisture collecting in the delivery tube from A. In all these experiments about 300 grms. of the broken pumice was used and after the above treatment about 40 grms. of nickel was deposited on it. The oleic acid was contained in the distilling flask, B, which was sealed on to the tower, and into which a tube passed through which hydrogen could be delivered into the apparatus.

The hydrogen used was generated by means of a Kipp apparatus, and was purified by passing through wash-bottles containing silver nitrate and strong sulphuric acid and also through a U-tube containing small pieces of solid potash, as it is well known that the activity of a metal catalyst can be very greatly diminished and even completely suppressed if there are in the hydrogen even minute traces of certain substances such as arsenic.

The distilling flask containing the oleic acid was heated in an asbestos air-oven, C. The delivery tube from the glass tower fitted into a receiver, E, which was connected through a manometer to a water pump. The pressure could be easily adjusted to the required value by regulating the amount of hydrogen which was passing through and the rate at which the pump was working. The temperature of the oil-bath was so arranged that it was always kept a few degrees higher than the boiling point of tho oleic acid. It was generally kept at a temperature of about 300° C. to ensure that the catalyst was never in contact with liquid oleic acid but only with the vapour, as any oleic acid condensing after distillation, was again vapourised on passing down the tube leading into the bottom of the catalytic tower. The product of the reaction distilled out of the tower and condensed in the receiver, E.

The amount of reduction that had taken place was estimated by determining the iodine value of the resulting product by Wijs's modification of Hübl's method: 0·3 to 0·4 grm. of the substance, as a rule, was dissolved in 10 c.c. of chloroform and to this was added 25 c.c. of the iodine solution. The mean of several determinations gave 79 as the iodine value of the oleic acid which was being used.

The following are the results obtained in the distillation of oleic acid through the catalytic tower under varying pressures. Firstly, distillations were carried out at a pressure of 100 mm. The resulting product had an iodine value of 75. This figure was obtained as mean of three separate distillations and corresponds to a reduction of about 5%. As a check on this figure, a 5% solution of stearic acid in oleic acid was made and its iodine value was determined and found to be the same as above, viz., 75.

In order to see if any further reduction could be obtained the 5% reduced product was redistilled over the catalyst at the same pressure as previously. On determining the iodine value of the product obtained as the result of this redistillation, it was again found to be about 75, showing that no further reduction had occurred. Another redistillation of this substance again caused no change in the iodine value and consequently no change in the amount reduced.

It was thought that possibly this result was due to the catalyst having become poisoned through some cause or another and lost its activity, but on distillation of a fresh portion of oleic acid over it, a reduction of 5% was again obtained.

Distillations were next carried out at a pressure of 150 mm. Two separate distillations at this pressure gave products having iodine values of 70 and 68 respectively, which is equivalent to about 14% reduction of the oleic acid. These products on redistillation gave iodine values of about 67, which is nearly identical with the preceding ones and is equivalent to a reduction of about 15%. Identical phenomena were observed on distillation at a pressure of 200 mm. Here the reduction was about 20%, and redistillation again did not cause further reduction.

These results appeared to point to the existence of an equilibrium in the vapour between stearic acid, oleic acid, and hydrogen, and that the amount of reduction obtained, which varied from pressure to pressure but was constant at any one particular pressure, was the equilibrium amount of stearic acid under those particular conditions. If this were so it should be possible by distilling stearic acid over the catalyst to cause it to decompose into oleic acid and hydrogen until the quantities produced were the equilibrium quantities under those particular conditions. To test this, stearic acid was placed in the distilling flask and distilled over the catalyst in precisely the same manner that the oleic acid had been distilled, freshly made catalyst being used. Both before and after distillation the iodine value of the stearic acid used was found to be zero, no iodine at all being absorbed. Another distillation of the same substance failed to cause it to have any appreciable iodine value. The result of these distillations showed that none of the stearic acid had been converted into oleic acid and seemed to preclude the idea of an equilibrium.

The next thought that suggested itself to explain the fact that no further reduction takes place on repeated distillation, was that on redistilling the partially reduced product, fractional distillation took place and oleic acid only distilled over and was reduced to the same extent as previously, consequently the resulting product appeared not to have altered in any way. It does not appear, however, that this supplies the true explanation, as on redistillation by far the larger portion of the liquid was distilled over out of the flask into the catalytic tower, and also the boiling point of stearic acid does not differ by more than a degree or so from that of oleic acid.

If this phenomenon is due to neither of these causes it is difficult to explain it, but the fact most certainly remains that repeated distillations at any one particular pressure did not cause any change in the amount of oleic acid reduced after the first distillation.

Experiments were then carried out to determine how the amount of reduction in the liquid phase at atmospheric pressure varied with the length of time the substance was in contact with the catalyst. The same apparatus was used as before. The oleic acid was distilled into the tower under reduced pressure, the temperature of the oil-bath being kept too low for the oleic acid to distil out again. When as much oleic acid had been distilled in as was required the pressure was raised to atmospheric by allowing more hydrogen to come in and gradually turning the pump off. The temperature of the oil-bath was then raised to about 275° C., and at certain intervals of time small quantities were distilled out by reducing the pressure, and their iodine values were determined. After each distillation the pressure was again raised to atmospheric and the heating continued, hydrogen passing through the apparatus all the time. The following were the results obtained:—

Portion distilled after heating for—	Iodine value.	M. pt.
2 hours	67	23° C.
3½ hours	62	33° C.
5 hours	60	37° C.
9 hours	46*	50° C.

* This is equivalent to a reduction of about 45%.

Experiments under pressure.

Experiments were next carried out at pressures considerably greater than atmospheric, as it appeared quit feasible that at very high pressures the reduction coul be carried out at considerably lower temperatures an thus in the case of unsaturated glycerides the possibilit of decomposition would be removed.

The first few experiments were of a preliminary natur The apparatus used was a steel pressure cylinder whic had been tested up to a pressure of 300 atmospheres an to which a pressure gauge and a gas cylinder could attached. In order to be able to exhaust the cylinder its air before the hydrogen was compressed in, a thre way valve was designed and made, and was connect between the reaction cylinder and the gas cylinder. Wh the valve was open the reaction cylinder could be co nected to the pump and exhausted. After exhaustion w completed the valve was closed, and the reaction cylind was only connected with the gas cylinder, and hydrog to the desired pressure could then be passed into it. T catalyst, which was made as before, was contained in glass tube about 6 cm. in diameter and 30 cm. long, whi just slipped into the cylinder. A certain quantity of ol acid was poured on to the catalyst, the cylinder co screwed on and the various other gas-tight connectio made as quickly as possible, the apparatus then evacuat and hydrogen to the desired pressure passed in. T cylinder was then heated in an oil-bath to the desi temperature for a certain length of time.

The following are some of the experimental results Pressure in reaction cylinder, 50 atmospheres. Tempe ture of reaction cylinder, 250° C. The pressure fell in first ½ hour to 47 atmospheres and remained constant that figure for over 3 hours. The cylinder was then ope and the tube containing catalyst and oil removed, and its contents transferred to a distilling vessel the same as had been previously used for the experiments under reduced pressure, the only difference being that the sealed-on distilling flask, not now being required, had been cut out. The oil was then distilled out from the catalyst under reduced pressure; the iodine values of the products obtained in two experiments under these conditions were 67·2 and 66·9.

The great disadvantage of using the apparatus in this manner was that the oil had to be poured over the catalyst all at once, and rapidly falling to the bottom of the vessel collected there and consequently only a very imperfect contact between the oil, catalyst, and hydrogen was obtained, so in the final state the apparatus was modified in such a way as to allow the oil to be fed over the catalyst as slowly as possible.

The cover of the cylinder was drilled through, and a smaller cylinder, acting as a high pressure oil feeder, attached to it through a high pressure valve. The thread on the spindle of the latter was such that a very delicate regulation of the flow of liquid could be obtained. The upper vessel was connected through a T-piece and three-way valve to a hydrogen cylinder, a pressure gauge, and an exhaust pump (as in the case of the reaction-vessel). Both oil feeder and reaction vessel could therefore be separately and independently exhausted and filled with hydrogen to any desired pressure. The construction will be evident from the accompanying figure (Fig. 2).

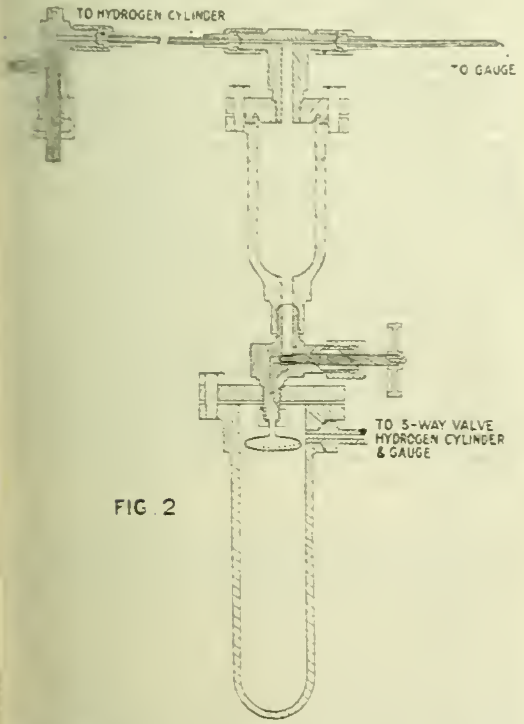

FIG. 2

The experiments were carried out as follows:—The atalyst, contained in the wide glass tube, was placed in he lower cylinder and the oil in the upper one. The pparatus was then screwed together.

Both cylinders were now exhausted, washed out with ydrogen, and then filled with hydrogen to the desired essures, the pressure in the oil-feeder being always several mospheres higher than that in the reaction-vessel in der to force the oil into the latter. The lower cylinder as heated in the oil-bath to the desired temperature, the hole apparatus being suspended from a pulley by means which it could be raised or lowered. Before running e oil in, the catalyst was usually heated in hydrogen at few atmospheres' pressure for an hour or so, to sure complete reduction to metallic nickel. This hydrogen was then pumped out and hydrogen up to the pressure required for the experiment run in. Everything being ready the spindle was turned slightly and oil allowed to run very slowly over the catalyst through a suitable sprinkling device. It was, of course, necessary to know the rate at which the oil was being delivered from the top cylinder, and owing to the high pressures being used it was impossible to have anything in the nature of a glass gauge which would show the level of the liquid in the upper cylinder. This difficulty was readily overcome however, as, the volume of the upper cylinder and the volume of oleic acid in it being known, a consideration of the reduction of pressure indicated by its gauge enables the amount of oil run out to be determined.

A concrete illustration will explain this. The volume of the upper cylinder was approximately 300 c.c., and the volume of oleic acid taken was 240 c.c. Therefore the original gas space was 60 c.c.

It is required to deliver the oil completely from the upper to the lower cylinder in 6 hours, *i.e.*, at the rate of 40 c.c. per hour. The original pressure in the upper cylinder was 70 atmospheres and in the lower 50 atmospheres. The gas volume at the end of half an hour when 20 c.c. have been delivered is 80 c.c. and the pressure registered by the gauge attached to the upper cylinder will be $70 \times \frac{60}{80}$, or 52·5 atmospheres. Consequently all that has to be done to ensure the oil being delivered at that particular rate during the first ½ hour is to see that the pressure drops steadily from 70 atmospheres to 52·5 atmospheres in ½ hour. This can readily be done by manipulating the spindle so as to allow less or more oil to run out as the case may be. As the pressure in upper cylinder has always to be greater than the pressure in the lower cylinder it is necessary at this stage to fill up again to 70 atmospheres. The gas volume is now 80 c.c. at a pressure of 70 atmospheres. At the end of the next ½ hour when another 20 c.c. will have run out the pressure will be $70 \times \frac{80}{100}$, or 56 atmospheres. The cylinder is filled up again to 70 atmospheres and the process repeated.

In this way the pressures, corresponding to an outflow of oil at this rate at intervals of time during the 6 hours can be calculated and by manipulating the spindle it is arranged that these calculated pressures are obtained.

The following are a whole series of pressures calculated for the delivery of 240 c.c. in 6 hours.

Pressures after ½ hr. $= 70 \times \frac{60}{80} = 52·5$ atmospheres.
" 1 " $= 70 \times \frac{80}{100} = 56$ "
" 1½ " $= 70 \times \frac{100}{120} = 58·3$ "
" 2 " $= 70 \times \frac{120}{140} = 60$ "
" 3 " $= 70 \times \frac{140}{180} = 54·4$ "
" 4 " $= 70 \times \frac{180}{220} = 57·3$ "
" 5 " $= 70 \times \frac{220}{260} = 59·2$ "
" 6 " $= 70 \times \frac{260}{300} = 60·6$ "

A series of experiments under the following conditions were made: Pressure in upper cylinder 70 atmospheres. Pressure in lower cylinder 50 atmospheres. Temperature of lower cylinder 150° C. Time of delivery of oil from upper to lower cylinder was 6 hours. After the reaction the contents of the lower cylinder were transferred to the distilling vessel and distilled; the iodine values of the products of two experiments came out as 82·4 and 83·2, the iodine value of the original oleic acid used in this series of experiments being 84·5, so that very little reduction had taken place.

Two more experiments were then carried out at a temperature of 250° C. The iodine value in each case was 81, so that in all these experiments the amount of reduction of the oleic acid occurring was considerably less than would be expected.

In all these experiments a brass rose soldered on to the lower part of the upper cylinder had been used as a sprinkler for the oil, and it was thought that possibly something had been dissolved out of this brass sprinkler and that this had had a poisoning effect on the catalyst, so it was cut out altogether and a glass sprinkler substituted.

An experiment carried out under the same conditions of temperature and pressure, gave now a product which had an iodine value of 52 which is equivalent to a reduction of 35%, so it appeared certain that some ingredient either of the brass or of the solder had poisoned the catalyst in the previous experiment. It is scarcely likely that the substance having an poisoning effect would be the zinc out of the brass as it would have no tendency at all to deposit on the nickel, neither would it be the copper, as copper itself acts as a hydrogenizing catalyst like nickel; it might, however, be the lead or tin out of the solder both of which are lower down the electro-motive series than nickel and would deposit on it.

A series of experiments were made and the following were the results obtained:—

(1) Pressure in lower cylinder, 50 atmospheres. Temperature of lower cylinder 250° C. Time of delivery of oleic acid from upper to lower cylinder was 6 hours. Iodine value of resulting reduced product was 52, which is equivalent to a reduction of about 35%.

(2) Pressure in lower cylinder, 25 atmospheres. Temperature of lower cylinder, 250° C. Time of delivery of oleic acid was 6 hours. Iodine value of resulting product was 64, equivalent to a reduction of about 20%.

(3) Pressure in lower cylinder, 5 atmospheres. Temperature of lower cylinder, 250° C. Time of delivery of oleic acid was 6 hours. Iodine value of resulting product was 77, equivalent to a reduction of about 4%.

From the above results it will be seen that increase of pressure causes an increase in the amount of reduction, the other factors, temperature, etc., remaining the same.

A few experiments were also carried out with cottonseed oil. The temperature at which the reduction was carried out was in this case 200° C. and the result showed a very considerable reduction of the glyceride. At the two pressures of 25 atmospheres and 50 atmospheres a reduction of over 50% of the glyceride occurred and a hard product was obtained having a melting point of about 50° C.

In conclusion I wish to thank Professor Donnan for his ever-ready assistance and advice, and also Dr. Harger for the kind loan of some of the pressure apparatus.

New York Section.

Meeting held at Rumford Hall, Chemists' Building, on Friday, May 22, 1914.

MR. G. W. THOMPSON IN THE CHAIR.

FERROSILICON AND ITS DANGERS.

BY CHARLES E. PELLEW.

In the spring of 1913 I was requested by the Secretary of the American Association for Labour Legislation to look into the dangers connected with ferrosilicon. I was informed that abroad it was generally believed that its transportation was extremely dangerous when the percentage of silicon was from 30 to 70%, and that stringent regulations had been established by at least one foreign government with regard to its transportation.

I was also informed that the Seventh Delegates' meeting of the International Association for Labour Legislation in 1912, in addition to adopting a set of principles for submission to the various governments on the methods of handling ferrosilicon, had also resolved that:—

"Further inquiries ought to be made into the question of whether ferrosilicon containing less than 30% or more than 70% of silicon involves a risk of poisoning or not, and into the possibility of prohibiting the manufacture of ferrosilicon containing from 30 to 70% of silicon."

This is the inquiry which I was requested to prosecute. My investigations, including a careful examination of the literature of the subject, personal inquiries at the offices of insurance and transportation companies, as well as visits to all of the principal works in the United States and Canada, have led me to conclusions radically different from those apparently accepted for years in Europe.

History of ferrosilicon.

For a long time it has been known that iron was capable of combining with different percentages of silicon, and in 1895, Moissan published in the Comptes Rendus a description of a true silicide of iron, prepared by electricity and also in a muffle furnace, consisting of 80% of iron and 20% of silicon, corresponding to the formula, Fe_3Si (see this J., 1896, 115). It was soon discovered that similar compounds, with varying proportions of iron and silicon, could be made without much difficulty in the electric furnace, but they were of little more than theoretical interest until, about 1902, it was found that these alloys of iron and silicon could be used to great advantage in the manufacture of steel. For many years one of the great problems in the steel industry was how to diminish and, if possible, avoid entirely the blowholes and pipes that were formed when steel, whether open hearth or Bessemer, was poured from the ladles into the large ingot moulds. It was often necessary to cut off 20 or 25% of the upper parts of the ingots before perfectly sound metal was reached. It was found that the addition of quite small amounts, say from ¾ to 1% of ferrosilicon, to the steel while in the ladle, evolved a great deal of heat from the combustion of the silicon. This not only thinned the metal considerably, but at the same time absorbed the oxygen dissolved in the steel, with the result that, on pouring into the moulds, perfectly solid ingots resulted with no blowholes at all. This very important discovery at once made ferrosilicon a valuable article of commerce and an essential factor in the stee industry of every part of the world. During the last few years another use has been found for it in the cast iron industry. Experts are using it more and more each year in foundry practice, sometimes to produce specia high silicon castings for use in electrical work; sometime to increase the fluidity of iron in castings; and sometime to substitute silicon for some of the combined carbon in th iron, thus enabling them to produce grey castings from white iron, by treatment in the ladle. As yet the deman for ferrosilicon from this source is not large as compared t that of the steel industry, but it is rapidly growing i importance.

Varieties and preparation of ferrosilicon.

The ferrosilicon of commerce is divided into two distinc varieties, differing not only in chemical composition, bu also in the method of manufacture. Low grade ferrosilicon containing not over 15% of silicon, is made in the blas furnace and, in fact, may be considered as a speci grade of pig iron. It is not very easy to make and, as th value of the product lies in the amount of silicon presen it is evident that it is very expensive to transport. T low percentage of silicon interferes greatly with its u as a fuel in the steel industry, and to some extent foundry work, and its manufacture is gradually dying ou

The ferrosilicon that is of so much importance to th world, nowadays, is the so-called "high grade" materia running from 15 or 20 up to 90% or more of silicon, whi can be made only in the electric furnace. The raw materia for its manufacture consist of (1) *iron*, in the form of scr iron, scrap steel, or iron ore; (2) *silica*, either quar sand, or sandstone; and (3) *reducing material;* commor either anthracite or coke, but occasionally, for the sa of great purity, charcoal, or oil coke. These materia in proper proportions, are melted together in a sim electric furnace, and the molten product, mixed with little slag, is drawn off at intervals, allowed to cool, brok into lumps, and stored or shipped.

Properties of ferrosilicon.

These, of course, vary with the comparative percentages of iron and silicon, and also, to some extent, with the requirements of the consumers. The steel men wish their ferrosilicon to be in lumps, containing a large proportion of silicon and yet not too light. If in powder or fine pieces it causes a tremendous ebullition when thrown into the almost white hot steel in the ladle, and a varying amount of the ferrosilicon is carried away in the fumes—causing a waste of valuable material, and at the same time introducing a condition of uncertainty about the composition of the finished product. If the silicon percentage is too low, much of the heat of combustion of the silicon is wasted in melting the accompanying iron. On the other hand, the specific gravity of silicon is less than one-third that of iron; and therefore, if the silicon is too high, the material may be so light as to swim on the top of the steel kettle and not distribute its heat and its materials uniformly.

Accordingly, the demand of the steel industry, in the United States and also abroad, is for large solid lumps containing not far from 50% of silicon. Another explanation, by the way, for this preference for the "so-called 50% grade," was given by Dr. Copeman in his elaborate report on ferrosilicon made in 1909 to the Local Government Board, in England.[*] He stated that the only reason for the employment of this grade that he had been able to learn, was "found in the facility its use affords to the workman in calculating the quantity of silicon required as an addition to any particular bath of metal." This would seem rather a reflection upon the education and intelligence of the European steel workers. Furnace men do frequently insist on having the composition of important raw materials kept as uniform as possible, so that they do not have continually to alter their charges. But it is surely unusual to have that composition kept at any particular percentage for the sake of saving some office clerk a few minutes' simple calculation.

In foundry practice the requirements are somewhat different, for the ferrosilicon is usually added in a powdered or granular form to the molten metal as it runs from the cupola into the casting pot. So the lumps so necessary for the steel men must be crushed into fine pieces before the iron men can use them. When not hampered by excessive cost, they prefer the percentage of silicon as high as possible, for often they must add silicon in considerable quantities, to get tho required composition in their finished iron, and if they used low grade ferrosilicon they would never be able to melt such a mass of solid material at the comparatively low temperature of the iron coming from the cupola.

It is claimed, further, by some manufacturers that the most economical output of their electric furnaces is ferrosilicon running near the 50% grade. When it gets much above this, they say that the extra expense of production makes each unit of silicon more costly to the consumer, a reason which, if true and not simply imaginary is undoubtedly the most conclusive one for making this the standard grade of the material all over the world.

Preparation.

The discovery of the valuable properties of ferrosilicon, and the resulting demand for it, happened to coincide with the collapse of the "boom" in the manufacture of calcium carbide. For two or three years around 1900 the anticipations that acetylene would speedily replace coal gas and water-gas as an illuminant on a large as well as a small scale, had induced engineers to put up electrical furnaces, large and small, wherever cheap water power could be obtained. When the demand for calcium carbide suddenly dropped, a great number of the small electric plants all over Europe, in Savoy, Switzerland, the Tyrol, Norway, Sweden, and even in Bosnia, turned with eagerness to the new industry, and began to put ferrosilicon on the market in large quantities.

The price at first was high, $110 or so a ton (calculated on the 50% grade), and, encouraged by this and by the duty of $4 a ton, the Electro-Metallurgical Company, of Niagara Falls, started to manufacture it in 1907, and have continued ever since, making on an average not far from 15,000 tons a year. Works were also started by the same company at Kanawha Falls, West Virginia, but the drop in the price of ferrosilicon to less than $60 a ton in 1909, and to $51·50 (f.o.b. Pittsburg) in 1911, due to keen competition, made these works unnecessary. In 1908 the Electro Metals Company started their works at Welland, Ontario, obtaining their power from the Canadian Falls at Niagara, and producing some 7000 or 8000 tons a year. This is consumed largely in Canada, but considerable quantities are shipped from there into the United States to the almost complete exclusion of European ferrosilicon. At present it is estimated that the average consumption of ferrosilicon in the United States is from 18,000 to 20,000 tons a year, of which 3000 to 4000 tons are imported from Canada. Nine-tenths or more of this material is of the 50% grade, and during the past year, 1913 to 1914, the average price, at Pittsburg, was about $71 a ton.

Dangers connected with ferrosilicon.

A short time after the introduction of ferrosilicon into commerce it was reported as being distinctly dangerous, not so much to those engaged in manufacturing it, as to those employed in handling and transporting it.

A. Dangers of explosion.—In January, 1904, an explosion occurred, at Liverpool, in a cargo of ferrosilicon from Trieste which had been standing on the dock for some four weeks. The material had been shipped in iron drums and while these were being placed in a warehouse two of them exploded violently. It was supposed that the trouble was due to pent up gases, and so, to save further accidents, the ferrosilicon was transferred into wooden barrels with holes bored in the top. But, ten days afterward, when one of these was being handled, it also exploded, shattering the barrel and severely injuring the workmen. A very careful investigation of the whole matter was made by two Government officers, Dr. Dupré, Chemical Adviser to the Home Office, and Capt. Lloyd, His Majesty's Inspector of Explosives, and their report is given in full in the Journal of the Iron and Steel Institute for May 5th, 1904 (see this J., 1904, 622). They reported that the explosions, in their opinion, were due to the combustion of an inflammable gas, mainly consisting of phosphoretted hydrogen. At the end of their report they pointed out the possibility of very serious accidents resulting from this condition of affairs and urged everybody who had to store or handle ferrosilicon to be fully alive to its possible dangers, "and, by keeping it in a dry and thoroughly well-ventilated place, prevent the accumulation of inflammable gas as far as possible." At the same time analyses were published, made by W. Watson Gody, showing the percentage of silicon to be from 53·80 to 59·40, and proving the presence of small quantities of both calcium and phosphorus, 0·14% and 0·056% respectively, and also of 0·218% carbon. He said also, that besides phosphoretted hydrogen in the gases from the casks, he found acetylene and arseniuretted hydrogen in small quantities.

While these explosions were the only ones publicly mentioned at this time, it was found a few years later that at about this period, *i.e.*, 1903 to 1904, one of the great English steel companies had been getting 50% ferrosilicon from the Continent, in iron drums, and that when they were opened with crowbars, almost every other one produced an explosion. These, however, were not as a rule violent, and no workmen were injured.

The explanation was probably as follows. As previously mentioned, during the first few years the ferrosilicon industry was an after-growth of the declining calcium carbide trade. The factories were small, situated in the mountain districts of Europe, and the same furnaces were frequently used alternately for the one or the other product, according to the temporary demand, without any real pains being taken to clean out the hearths or to keep the raw materials distinct. Accordingly early analyses show the presence of calcium in quite large amounts (*e.g.*, in 6 samples of ferrosilicon analysed in 1901, the calcium ran from 0·79 to 14·4%), associated with both carbon and phosphorus. If the iron drums, in which the material was shipped, were perfectly tight, and if it were perfectly dry to start with, no damage would be done, but if the material were packed while wet, or if the drums were old and leaky, and the contents got damp, then enough acetylene and phosphoretted hydrogen would be produced to form an explosive mixture with the air, which might be ignited by sparks from tools, or even from friction of pieces of ferrosilicon on each other. Under ordinary conditions the amounts of this gas would not be enough to cause serious trouble. But in the Liverpool case enough moisture was absorbed through the packages by the three weeks' exposure on the docks, in December, to accumulate a bursting charge.

---

[*] Copeman's Report, p. 109.

Several suggestions were made in the report with a view to avoid further explosions, such as (1) to fill the drums with high flash-test paraffin oil, which would keep both air and moisture away from the ferrosilicon, and, at the same time not be liable, itself, to ignition; (2) to pack the ferrosilicon, dry, in watertight drums, free from any water: (3) to keep the material wet for several days before shipping it, so that any gases should escape before it was packed for transportation. As far as I can find not one of these suggestions was generally adopted. But very possibly owing to the wide interest excited by these explosions, the packing of ferrosilicon in tight iron drums seems to have been largely if not entirely abandoned, and, as the manufacturers, at the same time, have learned the importance of keeping their product free from calcium carbide, no further explosions have been reported.

B. Dangers from poisoning.—To this change in the methods of packing is perhaps due the fact that, not very long afterwards, cases began to be reported of serious illness and even of death, where people were exposed to fumes arising from wet ferrosilicon.

1. "*Vaderland.*"—The first of these to be reported occurred in January, 1905, on the S.S. Vaderland, bound from Antwerp to New York, with 72 cabin and 951 steerage passengers, and an assorted cargo. When New York was reached after a very rough voyage, the officers reported some 50 cases of illness in the steerage, and 10 deaths, while another died on board ship, two days after reaching port. The ship was sent back to Quarantine and held there, while the passengers were taken to Hoffman's Island, and kept under careful supervision. The ship's doctor reported the cause of deaths as "acute pulmonary congestion and pneumonia." Autopsy by the health officer of the port indicated "pneumonia complicated by nephritis." The passengers themselves made charges against the steamship company of bad food, improper sleeping accommodation, and insufficient ventilation. The officers, on the other hand, pointed out that the passengers, mostly Hungarian field hands, came on board in poor physical condition, underfed and very poorly clothed, and had suffered greatly from seasickness, while the sea had been so high that they had been kept below hatches almost all the way.

The symptoms, both at sea and in port, did not correspond exactly with those of pneumonia, and, after landing, the cases rapidly improved. But for the first few days additional interest was excited by the suggestion, widely spread by the press, that the trouble was due to an outbreak of "pneumonic plague," a rare and extremely deadly variety of the well-known bubonic plague, where the infection attacks the throat. Some 250 of the patients, who seemed to be perfectly well, and had not been in close quarters with the sick, had been allowed to land before this suggestion of "plague" had been made, and much trouble and annoyance resulted from trying to collect these all again, and get them back under observation. Finally, after some weeks of careful inquiry, it was decided that the trouble was caused by the evolution of poisonous gases from 591 barrels of high-grade ferrosilicon, stored in the hold immediately below the steerage quarters.

2. *Keadby canal boat.*—In October, 1905, an English doctor found a family on a canal boat seriously ill from some unknown cause. The two children died, and the parents suffered severely, but recovered. A peculiar and very pronounced smell was noticeable in the cabin, and, on examination, five tons of high grade ferrosilicon packed in boxes was found in the cargo. On analysis, the ferrosilicon showed the presence of 7% calcium and 1½% carbon (phosphorus not determined); and it was shown that the weather was wet, and that it had been necessary to cover the cargo with sail cloths, to protect it from the rain. The coroner's jury attributed the deaths to poisonous fumes arising from the ferrosilicon, and reported their conclusions to the Board of Trade.

3. *Rhine canal boat.*—In March, 1906, two children died on a German canal boat, and their parents, who stayed on deck most of the time, suffered severely from headache and giddiness. On investigation it was found that besides other cargo, the boat was carrying 750 tons of high grade ferrosilicon, which was being brought down the Rhine from Switzerland to go to Essen. The cabin occupied by this family was directly above the hold containing the ferrosilicon, and it was believed that the gases had been drawn up through the under deck, by an updraught caused by lighting a stove in the cabin. The case was carefully investigated by Dr. Lehnkening of Duisberg, where the family were treated, and in his report he refers to four other cases where illness and death had occurred on Rhine cargo boats, caused in each instance by fumes from ferrosilicon in the cargo.

4. *Swedish steamship "Olaf Wyjk."*—In February, 1907, a Swedish steamer from Gothenberg, with six passengers aboard, arrived at Antwerp after a three days' passage. Four of the passengers died on the way, and the captain, stewardess, some of the crew, and the two remaining passengers were made seriously ill, but recovered.

One of the passengers was a well-known Russian revolutionist, escaped from Russia, and ordered out of Sweden upon the demand of the Russian Government. His deat under these strange conditions created great excitement among the Socialists in Sweden and elsewhere, wh practically accused the two Governments of contriving a deliberate murder. A thorough investigation wa accordingly started in both Stockholm and Antwerp, an after several months' work the chemical and medical expert who were interested in the case showed conclusively tha the trouble was caused by the presence of 15 tons of 50 ferrosilicon, stored in the hold just underneath the sleepin quarters of passengers and crew.

They showed that under the influence of the damp air i the hold, aided by the friction due to the motion of th ship, this ferrosilicon produced large quantities of poisonou gases, composed of 95% phosphoretted hydrogen and 5 arseniuretted hydrogen.

5. *Swedish ship "Uleaborg."*—In May, 1908, whil this ship was sailing from Stockholm to St. Petersbur nearly all the crew and the second class passengers we taken seriously ill, and two of them died. The illness w traced to the gases evolved from some 45 tons of ferr silicon in the hold.

6. *English keel "Harry."*—In October, 1908, this bo was carrying goods on the canal to Sheffield, when th captain and mate died, and a woman was taken dangerous ill, but recovered. In the cargo was a shipment of barrels marked "scrap iron," which, on investigatio found to be high-grade ferrosilicon, on its way fro Antwerp to Sheffield. In a suit for damages brought lat by the widow against the shippers, it was proved in cou that this was the cause of death.

7. *Other English canal boats.*—About this time, appeared in a later investigation, other cases of poisoni took place on canal boats carrying ferrosilicon to Sheffiel In one of these two boys, and in another two children, we made seriously ill, but recovered, while a dog that was the same cabin for a greater length of time, died.

8. *English steamship "Ashton."*—The last of this seri of accidents, which impressed on the authorities all o the world the possible dangers of ferrosilicon, occurred December, 1908. On the 24 hours' trip of an Engli steamer from Antwerp to Grimsby, all the emigra passengers aboard, fortunately this time only five number, died some hours before reaching port.

The British authorities at once started a most ri investigation, and it was soon shown that the deat were caused by poisonous fumes, mainly consisting phosphoretted hydrogen, evolved from about nine t of high-grade ferrosilicon, stored in the hold immediat under the emigrants' quarters.

After this accident the British Government took up the matter seriously. A committee, consisting of Dr. Copeman, Medical Inspector of the Local Government Board, Mr. Bennett, a Government Inspector of Factories, and Dr. Hake, was appointed to make a thorough investigation of the whole subject, and in 1909 their report was printed, as a "Yellow Book" of 115 pages, forming a supplement to the 38th Annual Report of the Local Government Board.

British Government report on ferrosilicon.

This elaborate and carefully prepared report not only takes up the properties, uses and dangers of ferrosilicon, but gives the result of conferences with manufacturers of ferrosilicon on the Continent as well as with importers and users of it in Sheffield. It describes the action taken by manufacturers and transport companies in Europe to prevent accidents from it, as far as possible, and mentions the official orders and regulations on the subject in England and other countries.

For our purposes the most important part of the document is Dr. Wilson Hake's report on the chemical investigation of ferrosilicon, upon which are chiefly based the conclusions and recommendations with which the committee closes its investigation.

Chemical report on ferrosilicon.

This covers the physical as well as chemical examination of 64 samples of ferrosilicon obtained from English and foreign manufacturers, and varying in composition from 4 to 96% of silicon.

As impurities to be met with in commercial ferrosilicon the committee mentions *calcium phosphide*, due to the reduction of calcium phosphate (phosphate of lime) commonly present in the quartz and coal of the raw materials. This material is readily decomposed by moisture, forming lime and the extremely poisonous phosphoretted hydrogen, and it is mentioned as the source of the latter gas in the poisonous fumes.

Arsenic is sometimes present, probably derived from the same raw materials, in the form of calcium arsenide, which, when acted on by water, is the source of the arseniuretted hydrogen sometimes recognised in the fumes.

Calcium carbide was commonly found in the earlier specimens of ferrosilicon made in carelessly cleaned carbide furnaces, but is now rarely if ever found. In moisture this evolves acetylene, a gas which is not poisonous, but is inflammable, and, when mixed with air, is explosive. The whole report shows conclusively that the poisonous properties are due to the evolution of phosphoretted hydrogen by the action of water upon calcium phosphide, existing as an impurity in the ferrosilicon. Special apparatus was designed by Dr. Hake, for the purpose of determining the least amount of this gas that could be produced from these samples. And he makes careful mention on page 84 that, when any gas had been evolved by the action of water upon one of the samples, the contents of the flask were *invariably* alkaline to litmus, and that the water used contained *free lime.*

Influence of silicon percentage on evolution of poisonous gases.

While recognising that the dangers of ferrosilicon were due to the impurities present, and especially to phosphide of calcium, the committee seems to have made up its mind from the very beginning that these impurities were unavoidable, and they concentrated their efforts in attempting to trace a relationship between the percentage of silicon, in the different samples they examined, and the evolution of phosphoretted hydrogen.

In every case of poisoning that has been reported the ferrosilicon was high grade, and when analysis had been made, the amount of silicon had been reported as between 50 and 60%. This committee noticed that there was a great difference in the physical condition of the different samples which they examined. When freshly made, ferrosilicon is in the form of a solid mass, with metallic lustre, not very different from some varieties of cast iron, ferromanganese, and other iron alloys. This is particularly the case with the low-grade ferrosilicon, which is practically nothing more than a highly silicious pig iron. The very high grade material, 70, 80, and 90 or 95% of silicon, is also, while light, very dense and solid. But the intermediate grades, they found, are apt to be more or less porous and loose in structure, and on standing, show a marked tendency to disintegrate, and break down into powder.

With this disintegrating property, they also found an increased evolution of poisonous gas, which they attributed to the large surface of material exposed to dampness. And Dr. Hake gives as his general conclusion, based upon his examination of the 64 samples examined by him, "that these might be classified in three groups, viz. :—

"Class I., 10 to 30% silicon, containing practically no poisonous impurities, and not liable to spontaneous disintegration.

"Class II., 70 to 96% silicon, not entirely free from poisonous impurities, but also not liable to disintegrate spontaneously.

"Class III., 35 to 60% silicon, containing, in most instances, a considerable proportion of poisonous impurities, and in addition being more or less liable to spontaneous disintegration."

This conclusion about the dangerous influence of certain percentages of silicon was further emphasised in the elaborate and highly technical report, contained in the same "Yellow Book," upon the "composition and structure of ferrosilicon," by Mr. Bennett. He closed his paper with the following statement—"The amount of gases given off by different grades of ferrosilicon depends not only on the impurities present in the materials used in the electric furnaces, but also on the physical properties of the alloys, in consequence of which, in certain cases, access of moisture is afforded to a much larger extent of surface."

The final conclusion of the committee was that it was impossible to control the poisonous properties of ferrosilicon by any care with regard to pure raw materials: that practically all ferrosilicon of the 50% grade was liable to give off poisonous gases when exposed to moisture; that low grade ferrosilicon (10 to 15%) did not evolve these gases, even in the presence of moisture; that certain grades of electric furnace ferrosilicon were practically quite innocuous, these grades being 30% and under, and probably, though not so certainly, 70% and over.

Therefore, in view of the fact that the dangerous grades were apparently not essential in the iron and steel industry, except perhaps for making basic steel, they advised "that the production of this alloy of grades ranging between these percentages should be discontinued in the future."

They also urged the iron and steel men who used ferrosilicon to assist by limiting their orders to the safe grades, and they suggested the following regulations, which were officially adopted by the Board of Trade.

Board of Trade Regulations.

1. That the ferrosilicon should be broken into pieces of the size usually sold, and stored in the works, exposed to air, for at least a month before shipment.
2. Each package to be marked in bold letters, with the name and percentage grade of the material; the name of works where produced, the date manufactured, and the date of shipment.
3. Its carriage on passenger ships to be prohibited. On cargo vessels it should be stored on deck, or in well-ventilated holds, separated from quarters of the crew by air-tight bulkheads.
4. The same rules to apply to river and canal barges as to sea-going vessels.
5. Storage places for ferrosilicon at docks or at works where used, to have free access of air, and to be away from work-rooms, mess-rooms, offices, etc.

Further regulations with regard to ferrosilicon.

As a result of this very thorough and elaborate government investigation, the attention of iron and steel men and of shipping agents, all over the world, was called to the dangerous properties of ferrosilicon. In France a committee of manufacturers studied the whole matter very thoroughly and in their report, which appeared soon after the English "Yellow Book," they confirmed the conclusions reached in the latter. Everywhere in Europe it was conceded that the grades between 30 and 70% were dangerous, and must be manufactured, transported, and used as little as possible.

The United States still persisted in calling for these grades, and it was found very difficult to supply them. Some manufactures tried shipping it in lumps carefully coated with paraffin, to protect it from moisture, to the great annoyance of the steel workmen who had to shovel it into the melting pots. Others proposed using tight iron barrels filled in with low flash point paraffin oil.

Later Board of Trade Regulations.

In July, 1912, the British Board of Trade issued an order, which took the place of their previous orders on ferrosilicon, issued in September, 1907, March, 1909, and February, 1910, and which is still, I believe, in force. In this shippers were warned that the carriage of ferrosilicon between 30 and 70% was highly dangerous, and was prohibited on both cargo and passenger vessels. Above and below that grade, it could be carried on deck, on either passenger or cargo boats, if broken in pieces and stood for a month before shipment and packed in strong wooden cases pierced with holes on each side and properly labelled; when carried on a deck with sleeping accommodation it must be separated from the nearest cabin by clear space of at least six feet.

On cargo vessels it might also, after complying with the above conditions, be carried in adequately ventilated places under deck; but it must then be separated by air-tight bulkheads from any quarter occupied by crew and from any food-stuff or other cargo liable to be damaged by poisonous fumes.

United States Regulations.

In this country the government authorities issued much simpler orders on the subject. On February 24th, 1912, the Register of the Treasury Department at Washington, issued an order in which he "holds ferrosilicon to be a dangerous article, not transportable on passenger vessels."

A letter dated March 1st, 1912, received by one of the great trans-atlantic steamship companies, from the Department of Commerce and Labour, contains the following ruling. "The matter of whether ferrosilicon, packed in casks, may be transported on steamers carrying passengers, having been under consideration by the Department under date of February 24th, 1912, File No. 47911, this Bureau advised the Collector of Customs, at New York, that 'in the existing condition of the law, therefore, as I understand it, the transportation of ferrosilicon *in any form* on steamers carrying passengers is unauthorised.'"

Steamship companies' rulings.

Besides these government orders, the different transportation companies have adopted special rules and regulations of their own upon the subject of carrying ferrosilicon, these applying not only to the importation of it, but also to its exportation, and, in some cases at least, covering a strangely wide range of articles.

As far as can be learned by careful inquiry these rules have not been due to any action on the part of insurance agents. At the office of the Board of Marine Underwriters of New York, in the spring of 1914, neither the secretary nor any of his staff had ever heard of any danger of any sort connected with the transportation of ferrosilicon, and positively refused to believe that there was anything at all unusual connected with it. A few months earlier a friend in the office of a large underwriting house obtained, in a few minutes, over the telephone, an offer of insurance for a large lot of ferrosilicon, from Antwerp to New York, at the rate of 25 cents per $100.

It was a very different question, however, when it came to asking for transportation for this same material from the various steamship companies. All of them refused to take it, absolutely, on cargo as well as passenger vessels, and he was assured that the only way to bring it over would be by a special arrangement with some "tramp" cargo-boat.

At many of the offices reference was made to a book, "Dangerous Goods" published in Antwerp, 1910, by Dr. Julius Aeby, consulting chemist to one of the great trans-atlantic lines. On page 172 is the following:— "Ferrosilicon—solid—may give off poisonous and explosive gases (arseniuretted and phosphoretted hydrogen). Has been the cause of several accidents with mortal issue. It seems that the brands containing 15% silicon, or less, are not dangerous."

But, not content with this, on pages 166 to 171 inclusive, and 173 and 174, are the references to the following:— "Ferro-chrome-nickel; ferro-manganese-silicon; ferro-manganese; ferro-molybdenum; ferro-phosphorus; ferro-tungsten; and ferro-vanadium." Each one of these eight different alloys, produced in different parts of the word, and of great importance in many different branches of the steel and iron industry, is carefully included in this standard Reference Book on Dangerous Goods with one and the same statement made about each of them: "Ascertain if it does not show the same danger as ferrosilicon."

Silicon metal.

To show how far this scare, originating in the accidents caused by ferro-silicon, has spread so as to interfere with the ordinary rules governing transportation, the officers of one of the great transatlantic lines showed me some interesting correspondence on the subject of silicon metal.

In the autumn of 1909 the Carborundum Company of Niagara Falls had an order from the continent for some of this material, and wrote a careful letter to the steamship company to see if they would transport it for them. They explained that the material was made from pure glass sand and pure coke, was extremely resistant to all sorts of outside influences, such as air, heat, moisture, acids, etc., and they sent them samples, for examination, with the accompanying analysis, as follows: silicon, 92·56, iron, 3·09, aluminium, 2·75, carbon, 1·60.

This letter, with sample and analysis, was forwarded to Dr. Aeby, and in November, 1909, his answer arrived, as follows: "As in the case of all products manufacture by the electric current, this metal contains traces o carburet, phosphorus and arsenic, and in view of th accidents which this silicon metal has caused, you wil readily understand that I do not care to give you a *absolute guaranty* of this metal being 'not dangerous.'

"It is particularly impossible to base an opinion on few grams only, whether a quantity of several tons wil stand the movements of a vessel.

"As, however, the metal is very hard, and these trace are so small, I think there is no great risk in carryin it, especially if the manufacturer guarantees its inoffensiv ness.

"Yours truly," etc.

As a result of this report the shipment was refused.

What is the real cause of danger in ferrosilicon?

After studying carefully all the published informatio I could obtain on the subject of the poisonous properti of ferrosilicon, it seemed to me that one important par of the problem had not had sufficient attention given to i

The English investigators seem to have assumed th the dangerous constituents were a necessary part of a commercial ferrosilicon, and that the only thing th could do was to find out what were the conditions und which these supposedly necessary impurities could do t least harm.

This, however, is not the case. In perfectly pu ferrosilicon, consisting solely of iron and silicon, just in the silicon metal mentioned above, consisting solely silicon, iron, aluminium and carbon, there is absolute nothing which can give rise to any poisonous gases.

Surely, therefore, the simplest and most scienti way of attacking this problem is to find out first of a what the dangerous constituents really are—and then see if, by the natural laws of trade, if possible, and if no by regulations and legislation, these dangerous co stituents cannot be kept out of the commercial article.

The dangerous constituents.

There is no question, after looking over the evidence, that the poisonous gases evolved from ferrosilicon are composed always of phosphoretted hydrogen, with occasionally small amounts of arseniuretted hydrogen.

Now phosphoretted hydrogen can only be found in the presence of phosphorus; and, to give off this gas under the influence of moisture, the phosphorus must be combined with calcium in the form of *calcium phosphide*.

The presence of phosphorus, alone, in ferrosilicon would not be objectionable. Cast iron used for delicate casting, often contains 1% or more of phosphorus, and yet we do not hear of cooks being poisoned by sitting near the kitchen stoves on a damp day. Ferro-phosphorus is now being made with over 25% of phosphorus in it, and no reports have come in about its giving off poisonous fumes.

But every chemist knows that calcium phosphide in the presence of water gives off phosphoretted hydrogen. Even, as before mentioned, in the Yellow Book notice is taken of the presence of lime (calcium hydroxide) in the water in every experiment where this gas was evolved from a sample of ferrosilicon.

With regard to the arseniuretted hydrogen the case is much the same. Unless arsenic is present, and present in some combination, such as calcium arsenide, which will decompose when acted on by water, no arseniuretted hydrogen can be evolved. And the disintegration of the ferrosilicon, so strongly dwelt upon in the Yellow Book as a cause of danger, is probably due to the presence of these unstable calcium compounds in the impure ferrosilicon rather than to the particular percentage of silicon present.

If these suggestions are correct, it would naturally follow that, to prevent accidents from the shipment and use of ferrosilicon, the first thing to do is to keep out of the material the impurities—phosphorus, arsenic, and especially calcium—which are responsible for the evolution of the poisonous gases, and that only in case this is impossible is it important to pay attention to the question of the silicon content.

Experience of ferrosilicon manufacturers in the United States.

That this method of avoiding accidents is not impossible is shown by what has been thus far accomplished in America. In 1907, when the Electro-Metallurgical Company began to make ferrosilicon at Niagara Falls, they entered a market already controlled by cheap foreign competitors, who at once began to cut prices, so as to force them out of the business. Very sagaciously, they met this competition by supplying a particularly acceptable article, rather than by cheapening the price at the xpense of quality.

The steel people, as before stated, needed their ferrolicon in the form of solid lumps, of uniform composition, ontaining not very far from 50% silicon. It was of little r no importance to them if they got 60% or even higher, rovided the price per unit was the same, and the percentage d not vary more than 1 or 2% from one lot to another. ut it was of great importance to them to have it in lump rm, and they had been frequently bothered by the uropean ferrosilicon disintegrating, on the long journey, efore it reached them.

Influence of silicon percentage upon disintegration.

As a result of several years' close study of the disitegration problem from a practical standpoint, the iagara Falls people differ widely from the English comission as regards the importance of the percentage of licon. Their experience has shown them that there is n undoubted tendency to disintegrate in the grades pproaching 50%. This is most marked a little higher on e scale, the worst grade of all being, in their opinion, om 55 to 57% of silicon.

This disintegration does not take place at all, they clare, even at this point, without the presence of phosorus and calcium, as is shown by the perfect condition, ter months and years, of numerous samples of this oduct. But small amounts of impurities which would t affect the harder and more resistant grades, of, say, % and over, or 30% and under, would cause the 50% ade speedily to fall to pieces.

To avoid this disintegration, therefore, and without any particular thought of danger to workmen or handlers, a matter which at that time was barely coming into notice, the Niagara people decided to make the greatest efforts to use pure raw materials, and particularly to avoid the presence of phosphorus and later of lime. Instead of scrap iron or of iron ore, both of which are liable to contain much phosphorus, they used steel scrap, which is practically free from it. For fuel they used only the very best and purest metallurgical coke, and for the silicon they hunted far and near and finally bought a quarry for themselves, of an extremely pure grade of quartzite, instead of buying at much less expense in the open market.

Ever since they started they have kept the percentage of phosphorus in their product below 0·03%, with the most satisfactory results. I have been unable to find that a single case has ever been reported of poisoning or explosion, in connection with ferrosilicon in America, since the landing of the s.s. Vaderland, in 1905. Since they began to produce it in Niagara Falls, no case of poisoning, they declare, has occurred at the works; and careful inquiry from the offices of the United States Steel Company, and from freight agents connected with land and water transportation on and near the Great Lakes, has failed to disclose records of any trouble connected with its shipment or use.

Much the same record holds good with regard to the disintegration. For seven years the Electro-Metallurgical Company have been manufacturing and selling from 10,000 to 15,000 tons a year. This material has been stored in the open air for weeks, sometimes for months before shipment. It has been packed in packages not air-tight, and shipped, without special precaution to avoid dampness, for long distances on land and water, and stored for indefinite periods before using and yet, although of the particular 50% grade, which the European investigators have found so liable to disintegrate, this has remained in lump form until used.

Specimens of every batch have been kept at their office in Niagara from the time the Company started, and these, too, show no signs of disintegration.

On one occasion, however, they did have some trouble. They started to use a new brand of coke, equally low in phosphorus with that they had been in the habit of using, and, after standing for a few days in the open air, the ferrosilicon made with this began to crumble and break down. They at once investigated the matter, and found that while there was no increase in phosphorus, the ash of the new coke showed a much greater percentage of calcium than the former fuel, and on cutting this out the trouble was at once remedied.

As a rule the calcium in both ash and silicon, being due probably to the presence of calcium phosphate, had varied in proportion with the phosphorus present. But this case put them on their guard, and since then they guard against the presence of calcium even more carefully than phosphorus.

Similar experience of Canadian manufacturers.

The Electro-Metals Company, which started their works at Welland, Ontario, a couple of years after the Niagara Falls people began, were sufficiently intelligent to work out the problem in the same way. They could not find sufficient market for their output in Canada, and when shipping into the United States, had to compete with the United States product, and face the tariff, as well, at first of $4 a ton, then, in 1909, changed to 20% *ad valorem*, and later reduced to 15%.

They could not possibly compete by means of an inferior product. And so they, too, from the time they started, have taken the greatest pains to use pure raw materials, free from phosphorus and calcium. They use roasted Rio Tinto ore instead of the scrap steel successfully used by the Niagara people. But they take the same precautions with regard to their fuel and silica, and obtain equally satisfactory results, with a 50% product. They have never had any trouble with either poisonous gases or disintegration, and they ship their ferrosilicon, after standing in the factory yard, in loose barrels or even in burlap bags, without any danger of losing any in the form of dust or powder on the way, and without any complaints from their customers of its arrival in powdered form.

They informed me that the only experience of the action of phosphorus and calcium which they could report was that one of their customers, probably a cast iron man, wished his ferrosilicon in granules, not in lumps. And, to avoid the trouble of fitting up a crusher for his particular order they ran out a batch for him once or twice a year, containing some phosphide of calcium. This is stored, separately, in the yard, and wetted down or exposed to rain, with the result that in a few days' time it falls into powder.

I was interested to learn that the Canadians, too, had been touched by the attitude of the shipping authorities. A considerable order for ferrosilicon recently came to them from Japan, not only important in itself, but of considerable interest as possibly the starting point for a valuable export business. Unfortunately, on account of transportation restrictions, it proved to be impossible to ship it there, and the order had to be cancelled.

Conclusion.

As a result, therefore, of all the information that I have been able to gather, it seems to me that it would be a decided mistake for the United States to follow the foreign regulations with regard to the manufacture and shipment of ferrosilicon, based upon the supposition that the grades commonly used (containing between 30 and 70% of silicon) are necessarily dangerous. It seems to me that this supposition is distinctly erroneous, and that the danger attaching to much of the foreign ferrosilicon has been due, not to the percentage of silicon, but to the presence of avoidable impurities—phosphorus, arsenic, and especially calcium.

In the United States and Canada the natural laws o trade have in this particular instance brought about, a satisfactorily as government regulations could do, the us of pure materials and the production of a safe and stabl article. And, in my opinion, it is greatly to be regrette that the export of this pure ferrosilicon is hampered b foreign regulations based, I must conclude, upon insufficien investigation.

Patents.

Separation of liquid suspensions. The British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 13,465, June 10, 1913.

The liquid, *e.g.*, oil containing drops of water in suspension, is passed through a metal tube, provided on the outside with a number of discharge points, into the lower part of a cylinder of glass or other dielectric material coated on the outside with metal. The oil returns upwards through the annular space between the tube and the cylinder, and is subjected to electric discharges produced by connecting the metal tube and the outer metallic coating with a source of alternating current of about 15,000 volts. The separated water sinks to the bottom and is discharged, whilst the purified oil flows away from the top of the cylinder. —W. H. C.

Furnace; Regenerative ——. J. Reuleaux, Assignor to A. Laughlin, Pittsburgh, Pa. U.S. Pat. 1,098,171, May 26, 1914; date of appl., Oct. 23, 1913.

A descending flue from the furnace opens laterally into a slag and dust pocket in a regenerative chamber. A passage, which may be subdivided into narrow channels, rises from the pocket, and leads to chequer-work through which the waste gases then descend.—O. E. M.

Kiln and heater; Combination ——. C. D. Allan, Chicago, Ill. U.S. Pat 1,099,632, June 9, 1914; date of appl., Dec. 26, 1913.

The stack extending above the inner crown of the kiln, is surrounded by an enclosed tubular water heater, with which it communicates by adjustable openings, and has a damper at the top. A chamber in two compartments with an adjustable port between them and opening into the heater and the stack, which may be separated by annular space, may be placed at one end of the heater. —O. E. M.

Dryer; Rotary ——. W. E. Prindle, Manitowoc, Wi U.S. Pat. 1,098,402, June 2, 1914; date of appl., Ap 23, 1913.

Hot air is drawn from a chamber surrounding the fe end of an outer shell through a concentric inner shell the unenclosed end of the outer shell, and back throu the annulus, containing the material to be dried, betwe the shells.—O. E. M.

Dryer [for purified air]. J. C. Fleming, Boston, Ma U.S. Pat. 1,099,122, June 2, 1914; date of appl., Ja 22, 1913.

Air is passed through a purifying liquid, and through dryer containing animal charcoal packed between in and outer perforated walls within a casing. The charc may be heated.—O. E. M.

Clarifying liquids and thickening pulps; Apparatus ——. H. B. Lowden, Assignor to Colorado Iron Wo Co., Denver, Colo. U.S. Pat. 1,098,812, June 2, 191 date of appl., Dec. 27, 1912.

In a settling and separating tank the solids are moved t submerged outlet by a rake which is raised at the end a lowered at the beginning of its working stroke and actua from above by connections surrounded by partitions wh prevent agitation of the supernatant liquid.—O. E. M

Pulps; Apparatus for thickening ——. J. E. Rothw Butte, Mont., Assignor to Colorado Iron Works Denver, Colo. U.S Pat. 1,099,396, June 9, 1914; d of appl., Sept. 18, 1913.

The thickened pulp is raised by a pump or air lift from bottom of a tank to a receptacle which, through adjusta openings, delivers part of it for use and returns the ex to a space enclosed by a partition within the tank.—O. E

Evaporating and concentrating apparatus [for caustic liquors]. H. K. Moore, Berlin, N.H. U.S. Pat. 1,098,825, June 2, 1914; date of appl., Dec. 12, 1910.

THE caustic liquor is pumped through a series of exhausted evaporators, the lower ends of which are in the form of inverted cones and which have submerged vertical tubes passing through, and heated by, the condenser attached to the next evaporator. The last evaporator is steam-heated.—O. E. M.

Abrasives to grinding apparatus; Method of applying ——. H. K. Hitchcock, Tarentum, Pa. U.S. Pat. 1,099,366, June 9, 1914; date of appl., July 31, 1911. Renewed Mar. 27, 1914.

THE abrasive material for grinding machines is fed in a mass into the top of a hopper with sides converging downwards and provided with an outlet at the bottom. A stream of water is injected into the hopper from below and slowly and uniformly carries the abrading material in suspension from the hopper to the grinding machine. —W. C. H.

Filtering slimes; Process of and apparatus for ——. C. Butters, Oakland, Cal. U.S. Pats. 1,100,217, June 16, 1914; date of appl., May 26, 1913; 1,100,218 and 1,100,219, June 16, 1914; date of appl., June 11, 1913; 1,000,220, June 16, 1914; date of appl., June 14, 1913; 1,100,221 and 1,100,222, June 16, 1914; date of appl., Oct. 18, 1913 and 1,100,223, June 16, 1914; date of appl., Oct. 22, 1913.

A SUCTION filter-leaf is provided with an air-escape valve, a water-supply pipe and a liquid-pressure equalising valve, o that after the cake has been formed, water can be admitted into the interior of the filter-frame to saturate he filtering medium and discharge the cake.—W. H. C.

iltering slimes; Apparatus for ——. W. A. Stedman, Wonder, Nev., Assignor to The Butters Patent Vacuum Filter Co. U.S. Pat. 1,100,267, June 16, 1914; date of appl., Aug. 13, 1913.

HE fabric bag forming the filtering medium and stretched n the frame of a suction filtering leaf is made open cross the bottom and is closed by the suction during ltration.—W. H. C.

acuum: Producing and maintaining a high ——. F. M. Meyer, Osnabrück, Assignor to Sudfelt und Co., Melle, Germany. U.S. Pat. 1,100,694, June 16, 1914; date of appl., Dec. 16, 1913.

UCTION is induced by a jet of gas, which is not condensed, a pipe joining two vessels, the second of which is onnected with a suction exhaust.—O. E. M.

IIA.—FUEL; GAS; MINERAL OILS AND WAXES.

ethane; Inflammability of mixtures of —— and various gases. Leprince-Ringuet. Comptes rend., 1914, **158**, 1999—2001. (See this J., 1914, 737.)

HE upper and lower limits of inflammability were etermined for mixtures containing methane and oxygen the constant proportions, CH_4+2O_2, and also varying unts of nitrogen, carbon dioxide, and water vapour. he effect of added nitrogen was to lower the upper and ise the lower limit until the two coincided at a point rresponding to the composition: (CH_4+2O_2), 20·1, 79·9%. The effect of carbon dioxide was similar ut of different magnitude, 0·56 vol. of carbon dioxide ving an effect approximately equal to that of 1 vol. nitrogen. The effect of water vapour could also be presented in a similar manner, so that if the mixture, mperature, and humidity were known, all necessary cts as to the inflammability could be deduced from a gle diagram.—W. H. P.

Ammonia and hydrogen cyanide; Formation of —— in the distillation of coal. O. Simmersbach. Stahl und Eisen, 1914, **34**, 1153—1159 and 1209—1213.

USING different coals the author studied the distribution of nitrogen between coke, tar, ammonia, hydrogen cyanide and free nitrogen in the gas, at varying distillation temperatures. He also carried out experiments on the decomposition of ammonia in contact with coke at various temperatures, into its elements and to form hydrogen cyanide. In the distillation of coal the formation of ammonia occurs mainly at a temperature higher than that at which coking takes place. The temperature of maximum ammonia formation is not the same for all coals, but varies between 800° and 900° C. The thermal decomposition of ammonia, which in the case of the pure gas starts at about 750° and is very rapid at 800° C., is not appreciable below 900° C. in the conditions of dilution obtained during the distillation of coal. The hydrogen cyanide formed in distillation increases with the amount of ammonia and with rise of temperature, although when pure ammonia is heated with coke it reaches a maximum at 900° C. The hydrogen cyanide obtained is usually about 1·2% of the total nitrogen in the coal and 5% of the ammonia formed. Water vapour reduces the cyanide yield, and improves that of ammonia, while high velocity of the gas has the reverse effect. The degree of subdivision of the coal has not much effect on the ammonia yield or on the temperature at which the best yield is obtained.—W. H. P.

Naphthenic acids; Behaviour of —— in the refining of kerosene oil. E. Pyhälä. Petroleum, 1914, **9**, 1506—1507.

RUSSIAN kerosene distillates of various origin contained 0·2 to 0·9% naphthenic acids. On refining the distillates with sulphuric acid about 30% of the naphthenic acids were sulphonated and dissolved. Naphthenic acids separated from refined kerosene had neutralisation value 294·9 and contained 0·77% S, whilst those separated from the ordinary waste lyes had neutralisation value 260·6 and contained 0·31% S. Naphthenic acids from kerosene distillates which had not been chemically treated had neutralisation value 230 and contained 0·1% S. When these were sulphonated the neutralisation value was increased to 240 and the S-content to 3·64%, and they yielded metal salts of different character from those given by the other naphthenic acids. The disagreeable odour increased with the degree of sulphonation, and this supported the view (Z. angew. Chem., 1904, 616) that sulphur compounds are the cause of the bad odour. —C. A. M.

Gas analyses by fractional distillation at low temperatures. Burrell and Seibert. *See* XXIII.

PATENTS.

Fuel of high calorific value; Continuous process for treating by steam and converting moist organic matter of vegetable origin into ——. J. Anderson, Charkoff and J. Hippius, St. Petersburg, Russia. Eng. Pat. 13,924, June 16, 1913.

DISINTEGRATED peat, moist sawdust, etc., is heated to 160°—180° C. in a closed vessel by high-pressure steam, fresh material being continuously introduced at the top and treated material discharged from the bottom into a low-pressure cooler, where it is cooled by blowing air or any gas other than steam through it. From the cooler the treated material passes to the pressing and briquetting plant. The warm gases and the steam given off from the cooler are passed through the incoming raw material in a preheater.—W. H. C.

Coal-slimes; Drying ——. H. Brune and H. Horst, Assignors to E. Abresch, Neustadt-on-the-Hardt, Germany. U.S. Pat. 1,100,710, June 23, 1914; date of appl., Oct. 28, 1912.

COKE breeze is mixed with the coal slimes, and the mixture is briquetted without the use of a binder by a slowly increasing pressure.—A. T. L.

Waste from coal-mining and from coking installations; Utilisation of —— by mixing with coal sludge. C. Hilgenstock. Ger. Pat. 274,163, Nov. 6, 1913. Addition to Ger. Pat. 272,852.

In carrying out the process described in the chief patent (this J., 1914, 636), the heavier non-combustible material is deposited before the lighter coal dust, so that an upper layer suitable for gas-making and a lower worthless layer are obtained. According to the present patent, this separation into valuable and worthless products is aided by using waste poor in coal to form the lower, and waste rich in coal the upper part of the filtering bed.—A. S.

Coke; Process for the production of strong metallurgical —— as free as possible from sulphur. L. Franck. Ger. Pat. 274,853, April 12, 1912.

Phosphorite. phosphatic chalk, apatite, vivianite, or other form of calcium phosphate, is added to the coal before coking.—A. S.

Retort furnaces for the manufacture of coal gas, etc.; Heating of ——. Dessauer Vertikal-Ofen-Ges. m. b. H., Berlin. Eng. Pats. 7338 and 7466, Mar. 23 and Mar. 24, 1914. Under Int. Conv., April 14, and Nov. 1, 1913.

(1) In a furnace arranged for heating at will with coal-gas or producer-gas, a small quantity of producer-gas is always used with the coal-gas in order to keep the producer and the adjoining conduits hot enough to enable heating with producer-gas to be resumed without delay. To prevent an excessive production of gas when the doors of the producer are removed for clinkering, the supply of coal-gas may be reduced at the time, or the conduits leading producer-gas to the furnace may be throttled, or they may be always of a suitably restricted area. (2) To prevent the production of luminous flames while the furnace is being heated with coal-gas, the gas is passed through incandescent fuel in the producer, being admitted to the producer at a point above the grate.—A. T. L.

Coke-oven or gas-furnace. W. Feicks, Bloomfield, N.J. U.S. Pat. 1,098,374, June 2, 1914; date of appl., Jan. 3, 1912.

The charging orifice in the top of a coke-oven or furnace is surrounded by a seal, and a charging hopper adapted to be brought over the orifice, is lowered so as to make an air-tight joint in the seal, whereupon further movement of the lowering mechanism opens the hopper valve. —A. T. L.

Coal-gas; Apparatus for manufacture of ——. R. C. Congdon, Atlanta, Ga. U.S. Pat. 1,099,639, June 9, 1914; date of appl., March 14, 1914.

A number of superposed horizontal retorts are connected with a single vertical pipe leading to a seal-box above the setting. The retorts can be disconnected from the gas up-take by means of hinged valves within the pipe, and liquor is passed down the pipe and on to the valves in order to keep them clean.—A. T. L.

Gas producer. J. F. Guggolz, Teague, Tex. U.S. Pat. 1,097,715, May 26, 1914; date of appl., April 2, 1912.

The producer comprises an inclined cylindrical casing having a grate which is parallel with the axis and is supported on transverse partitions. These partitions divide the space beneath the grate into an air-supply chamber at the upper part and a gas-outlet chamber at the lower part of the length of the producer casing, so that the gases pass first upwards and then downwards through the fuel. The fuel enters the producer chamber from a vertical cylindrical extension at the upper end. —A. T. L.

Gas producer. E. A. W. Jefferies and J. R. George, Assignors to Morgan Construction Co., Worcester, Mass. U.S. Pat. 1,097,757, May 26, 1914; date of appl., Dec. 1, 1910.

The lower end of the producer casing is formed by a water-jacketed metal wall, which is sealed in water in the ash-pan. Radial stirring arms which rotate about a vertical axis are arranged within the lower end of the casing, and the outer ends of these arms are attached to an inclined annular band, the upper edge of which extends behind a conical shield attached to the inner metal wall of the producer casing.—A. T. L.

Gas producer. H. F. Smith, Lexington, Ohio. U.S. Pat. 1,098,059, May 26, 1914; date of appl., Sept. 20, 1912

The producer comprises a rectangular casing with an inclined grate arranged along each of the longer sides A gas-outlet chamber extends centrally across the top of the producer parallel with the longer sides, and fue is fed into the producer at both sides of this chamber The grate-bars run perpendicularly to the length of th grate and are oscillated by cams so as to work the fue towards the middle of the producer. A separate ash-pi with separate blast supply is arranged beneath eac grate.—A. T. L.

Gas: Apparatus for generating ——. F. D. Shaw Chicago, Ill.. Assignor to Shaw Kiln Co., Atlanta, Ga U.S. Pat. 1,098,412, June 2, 1914; date of appl Feb. 18, 1910.

Liquid fuel is burned in a pan arranged in a recess ope to the atmosphere in the outer wall of a kiln. A pe forated tubular member depending from the top of th recess and extending downwards into the pan, leads to combustion-chamber, from which the hot gases pass int the kiln.—A. T. L.

Gas producer. A. J. Bassett, Assignor to Sharp-Basse Gas Producer Co., Milwaukee, Wis. U.S. Pat. 1,098,8 June 2, 1914; date of appl., Sept. 29, 1913.

The producer casing forms a jacket which is divid into three superposed chambers by means of two pe forated rings. Air is admitted to the top chamber, mix with steam generated in an evaporating pan in the midd chamber, and is led from the bottom chamber to the spa beneath the grate.—A. T. L.

Gas-generator: Cupola ——. H. Koppers, Essen-on-th Ruhr, Germany, Assignor to H. Koppers Co., Chicag Ill. U.S. Pat. 1,099,257, June 9, 1914; date of app Oct. 28, 1913.

A rotating gas-outlet pipe, extending vertically dow wards and arranged axially within the upper part of t producer, is flared outwards at the lower end which provided with parabolic bars for levelling the fuel so to form a paraboloidal cavity beneath the mouth of t gas-outlet pipe.—A. T. L.

Gas washer. T. W. Stone, Assignor to The Western G Construction Co., Fort Wayne, Ind. U.S. Pat. 1,098,1 May 26, 1914; date of appl., Oct. 4, 1911.

The washer comprises a casing containing the washi liquor, and two or more fixed bells, the lower edges which are sealed in the liquor, the gas being introdu into these bells and bubbling beneath their lower ed and through the liquor. Perforated plates, incli downwards and outwards, are attached to the outer wa of the bells, so as to mix the gases more thoroughly w the liquor as they pass up through it. These plates successively wider and have finer perforations, from lowest to the uppermost.—A. T. L.

Motor spirit similar to petrol; Manufacture of ——. T. Franke, London. Eng. Pats. 13,261, June 7, 15,459, July 4, 1913.

Peat tar is fractionally distilled and the distillat treated with oxidising and condensing substances (peroxides, persulphates and zinc chloride, alumini choride, etc.) to resinfy and precipitate the homolog of phenol. The treated material is again fractionally tilled and the high-boiling residue is heated to 300 under a suitable pressure in the presence of catal agents (pyrophoric iron, nickel, chromium, or platin to crack the heavy oil and form more motor spiri —W. H. C.

Oily substances; Fractional distillation of ——. H. Koppers, Essen on the Ruhr, Germany, Assignor to H. Koppers Co., Chicago, Ill. U.S. Pat. 1,098,734, June 2, 1914; date of appl., July 8, 1913.

In a steam-heated still the steam-trap is controlled by the pressure of the oil-vapour.—O. E. M.

Aluminium chloride [from residues from the treatment of petroleum oils]; Manufacture of ——. A. M. McAfee, Bayonne, N.J. U.S. Pat. 1,099,096, June 2, 1914; date of appl., Feb. 12, 1914.

Residues obtained in the treatment of petroleum oils ith aluminium chloride, are heated to remove oil, then eated to a higher temperature to carbonise residual rganic matter, and treated with chlorine or a gas conaining chlorine.—A. S

Lighting and heating gas or hydrogen; Process and apparatus for the manufacture of ——. Berlin-Anhaltische Maschinenbau-Akt.-Ges., Berlin. Eng Pat. 2054, Jan. 26, 1914. Under Int. Conv., Jan. 27, 1913.

See Ger. Pat. 267,944 of 1913; this J., 1914, 190.—T. F. B.

etermination of inflammable (reactive) substances in gaseous mixtures. Ger. Pat. 273,980. *See* XXIII.

roducing acetic acid and alcohol from coal, lignite, etc. Ger. Pat. 275,049. *See* XX.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Patents.

eat; Utilisation of [removing moisture from] ——. T. Rigby and G. W. Andrew, Dumfries, and Wetcarbonizing Ltd., London. Eng. Pat. 5873, March 10, 1913.

mall quantities of acid are added to the peat before bmitting it to the processes described in Eng. Pats. 7,610 of 1911 (this J., 1912, 1171) and/or 17,427 of 1912 his J., 1913, 1099) in order to facilitate the separation the water and reduce the loss of nitrogen.—W. H. C.

istillation of carbonaceous substances. H. Clarke, London, and J. T. Carmichael, Barking. Eng. Pat. 29,714, July 24, 1913.

ow-grade coals are prevented from caking on dis-llation in vertical retorts, by being mixed with either e solid residue of the process or other infusible material non-caking coal. A heated current of steam or other s containing hydrogen is passed through the mass to crease the yield of oils.—W. H. C.

r from hot distillation gases; Process and apparatus for recovery of ——. W. Strommenger, Cologne, Germany. Eng. Pat. 19,955, Sept. 3, 1913. Under Int. Conv., Sept. 28, 1912.

e Fr. Pat. 461,956 of 1913; this J., 1914, 245.—T. F. B.

ducing acetic acid and alcohol from coal, lignite, etc. Ger. Pat. 275,049. *See* XX.

III.—TAR AND TAR PRODUCTS.

Patents.

Bromo-2-aminoanthraquinone; Process for preparing ——. W. Junghans. Ger. Pat. 273,809, Nov. 17, 1911.

Aminoanthraquinone is treated with one mol. of mine in presence of an organic diluent, with or without lition of water. The bromine atom enters the 3-ution.—T. F. B.

β-Bromo-aminoanthraquinones; Process for preparing ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 275,299, Feb. 24, 1912.

Bromo-aminoanthraquinones in which at least one β-position *ortho* to the amino group is unoccupied, are heated alone or with sulphuric acid, phosphoric acid, zinc chloride, etc., to a temperature favourable to the migration of the bromine atom (*e.g.*, 160° to 240° C.).—T. F. B.

Anthraquinone derivatives; Process for preparing ——. R. Scholl. Ger. Pat. 274,783, April 12, 1913.

Dianthraquinonyl derivatives which contain in each anthraquinone nucleus at least one hydroxyl group in an *o*-position to the dianthraquinonyl linkage, are heated to high temperatures alone or in presence of a condensing agent. One mol. of water is eliminated, with the formation of a furane derivative.—T. F. B.

Anthraquinone derivative; Process for preparing an ——. R. Scholl. Ger. Pat. 274,784, April 12, 1913.

Alizarin or one of its salts is dissolved in a solution of potassium hydroxide and treated with a hypochlorite or with chlorine. Two alizarin molecules are thus united, with the loss of two hydrogen atoms, to form tetrahydroxydianthraquinonyl.—T. F. B.

IV.—COLOURING MATTERS AND DYES.

Diphthalylacridone. A. Eckert and O. Halla. Monatsh. Chem., 1914, 35, 755—763.

On condensing 1-amino-2-carboxyanthraquinone with 2-chloroanthraquinone, water is eliminated and a diphthalylacridone is obtained. The product is the 1.2.5.6-derivative, since it can be synthesised from an anthraquinone 2-halogen derivative where the 3-position is already occupied. It is a red crystalline substance soluble in sulphuric acid. When reprecipitated by water it is deposited in the amorphous form, and then readily forms a vat from which cotton is dyed reddish-yellow, changing into bluish-violet on exposure to air. The 3.4.6.7-diphthalylacridone (see Ullmann and Dasgupta, this J., 1914, 305) can be prepared by a similar method, using 1- instead of 2-chloroanthraquinone. Using 1-amino-2-methylanthraquinone and 2-chloroanthraquinone the product is 2-methyl-1.2′-dianthrimide. When this is fused with lead oxide and potash as described in Ger. Pat. 192,436, a substance is obtained the properties of which are quite different from those of the 1.2.5.6-diphthalylacridone.
—W. H. P.

Patents.

[Azo] dyestuffs capable of being developed; Process for preparing ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pats. 273,280, Jan. 8, and 273,934, May 17, 1913.

(1) A diazo compound of an aminodiarylsulphone, aminodiarylsulphoxide, or aminodiaryl sulphide is combined with an alkylbenzylanilinesulphonic acid. The dyestuffs thus obtained dye wool level yellow to reddish-orange shades, which are faster to washing and to fulling than those produced by other dyestuffs derived from alkylbenzylanilinesulphonic acids. The aminodiarylsulphones are described in Fr. Pat. 441,044 (see this J., 1912, 809), whilst the aminosulphoxides and aminosulphides may be obtained by condensing aromatic sulphinic acids with aromatic bases. (2) A diazotised mononitro- or acidylamino-arylacidyl derivative of an aromatic diaminosulphonic acid is combined with a pyrazolone or pyrazolonecarboxylic acid derived from an aminothiazole derivative, and the nitro group is reduced or the acidylamino group saponified. Thus, the dyestuff obtained by reducing the compound formed by combining diazotised *m*-nitrobenzoyl-*p*-phenylenediaminesulphonic acid with the pyrazolone from a dehydrothiotoluidinesulphonic acid, is a yellow

product, distinguished by its affinity for cotton fibre ; when it is diazotised on the fibre and developed with β-naphthol, reddish-yellow shades are produced.—T. F. B.

Azo dyestuffs ; Process for preparing ——. Farbenfabr. vorm F. Bayer und Co. Ger. Pats. 274,081 and 274,082, March 12, 1913.

(1) DIAZO or tetrazo compounds, or the intermediate products obtained by combining a tetrazo compound with one mol. of an azo dyestuff component, are combined with aminonaphthols or their sulphonic acids in which the amino group has been substituted with a sulpho-*o*-hydroxycarboxyl group. These substances are obtained by condensing *o*-hydroxycarboxylic acid sulphochlorides with aminonaphthols or their sulphonic acids. (2) The products obtained by condensing the sulphochloride of 2-naphthol-1-carboxylic acid with ammonia, amines, phenols, aminophenols, aminonaphthols, or their sulphonic or carboxylic acids or other derivatives, are used as azo dyestuff components. The carboxyl group may be eliminated if desired.—T. F. B.

Quinizarin-β-carboxylic acid ; Process for preparing ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 273.341, April 20, 1913.

THE methyl group of β-methylquinizarin is oxidised to the carboxyl group by treatment with nitrosylsulphuric acid in sulphuric acid solution. preferably in presence of boric acid. The product may be used as a lake or mordant dyestuff.—T. F. B.

Indigoid dyestuffs ; Process for preparing ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 274,299, Feb. 19, 1910.

DERIVATIVES of 2.3-diketodihydro-1-thionaphthene or its products substituted in the benzene ring, in which the 2-keto-oxygen atom adjacent to the sulphur atom is replaced by an arylido group, are condensed with α-anthrol and its derivatives which are unsubstituted in the *o*-position to the hydroxyl group. The products dye full, clear, fast violet shades.—T. F. B.

Indigo, its homologues or substitution products ; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 273,340, June 11, 1913.

o-AMINOACETOPHENONE, or one of its homologues or nucleus-substitution products, is heated with sulphur, with or without addition of a solvent or diluent, such as a high-boiling hydrocarbon or quinoline.—T. F. B.

Gallocyanines and their leuco-derivatives ; Process for preparing condensation products of ——. Farbwerke vorm. L. Durand, Huguenin und Co. Ger. Pat. 273,685, June 11, 1913. Addition to Ger. Pat. 189,940.

GALLOCYANINES are intimately mixed with aromatic diamines which contain at least one free amino group, with or without addition of a diluent and at the ordinary temperature ; the resulting products may then be converted into their leuco-compounds. When the components are only allowed to react for a short time in presence of a diluent, products soluble in aqueous sodium carbonate are obtained, with the carboxyl group of the original gallocyanine intact ; a longer period of reaction results in the elimination of the carboxyl group, with the formation of products insoluble in sodium carbonate solution.—T. F. B

Basic dyestuffs ; Process for preparing ——. L. Cassella und Co. Ger. Pat. 274.358, Jan. 9, 1913.

TETRA-ALKYLDIAMINOXANTHONIUM chlorides are treated with cyanides, and the products, which have no tinctorial properties, are oxidised to produce basic dyestuffs.
—T. F. B.

[Azo] dyestuffs ; Manufacture of yellow ——. Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. Eng. Pat. 15,163, July 1, 1913. Under Int. Conv., July 1, 1912.

SEE Fr. Pat. 459,468 of 1913 ; this J., 1913, 1101.—T. F. B

Dyestuffs of the anthraquinone series ; Process for producing ——. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany Eng. Pat. 22,911, Oct. 10, 1913.

V.—FIBRES ; TEXTILES ; CELLULOSE ; PAPER.

Wood for pulp ; Chemical evaluation of ——. M. Griffin. J. Ind. Eng. Chem., 1914, 6, 560—561.

THE cellulose in 24 samples of mixed spruce and bals fir from Montmorency, Canada, was determined by Cr and Bevan's chlorination method. The samples were obtained by quarter-sawing the piece of wood to be tested and planing thin shavings from the face of the quarter. No relation could be detected between the lensity of annual ring growth (number of rings per inch) and the sp. gr., or between the sp. gr. and yield of pulp. The yields of pulp ranged from 41·6 to 59·0% on the wood lried at 100° C., or from 901 to 1533 lb. per cord. The sults show the advisability of valuing wood for pulp nanufacture on the basis of the yield actually obtainable n a representative sample.—A. S.

Mercerisation as judged by the action of caustic soda upon regenerated cellulose. Beadle and Stevens. *See* VI.

PATENTS.

abrics; Treatment of —— for imparting wear-resisting, abrading and the like qualities. E. R. S. Lloyd, Hove, Sussex. Eng. Pat. 17,643, Aug. 1, 1913.

HE fabric is impregnated with a compound of lime and asein preferably by immersing it first in a finely levigated ilk of lime and then in a solution of cheese or casein sodium bicarbonate.—J. F. B.

d [sulphite] lyes; Method of and apparatus for neutralising ——. P. G. Ekström, Harnäs, Sweden. U.S. Pats. 1,098,561 and 1,098,562, June 2, 1914; date of appl., Feb. 24, 1912.

ULPHITE lyes and other liquids obtained by boiling llulosic materials with acid liquids, are neutralised ith a heavy solid neutralising agent preparatory to rther treatment for the production of alcohol. The lid neutralising agent is added to the liquor in a vessel rovided with a conical bottom, at the apex of which is nozzle having helical passages. Air under pressure is pplied to the nozzle, whereby a spiral jet of air, entraining e solid reagent, is forced upwards through the liquor. he neutralised liquor is drawn off near the surface through phon-pipe supported by a float. Water under pressure ay be forced through the nozzle, when desired, to sh the bottom of the vessel, the flush water being drawn through a pipe in axial alignment with the nozzle.—A. S.

nts for cellulose; Process for preparing ——. M. Wassermann. Ger. Pat. 274,658, Jan. 10, 1913.

UPROUS oxide is mixed with ammonium chloride and solved in ammonia at a low temperature, and caustic tash or soda solution is added until a bright blue ecipitate forms; this dissolves comparatively slowly in cold, and is separated from the liquid, which is used a solvent for cellulose.—T. F. B.

stic masses for artificial silk and other shaped articles; Process for preparing ——. H. Timpe. Ger. Pat. 275,016, Oct. 5, 1913.

BOUT 2% of alkali (*e.g.*, sodium hydroxide) is added to lk, and the albumin is precipitated from the filtered lution by means of dilute acid, washed, and dissolved in alkali; this solution is allowed to stand for about hours at 18°—20° C., and dilute acid is added, whereupon viscous mass is precipitated, which becomes elastic hen heated and can be drawn out into long, thin filaments: these are finally rendered insoluble by treatment th formaldehyde, a chromium salt, etc. Especially d results are obtained if about ¼% of hydrogen peroxide lution is added to the alkaline solution before pretation.—T. F. B.

n-soap sizing composition. J. A. De Cew, Montreal. U.S. Pat. 1,099,168, June 9, 1914; date of appl., June 13, 1912.

OSIN is boiled with a proportion of alkali less than that quired for complete saponification (*e.g.*, less than 16% sodium carbonate) and tannin is added to the product. —J. F. B.

Paper; Method and apparatus for making ——. L. B. Buchanan, Woburn, Mass. U.S. Pat. 1,101,725, June 30, 1914; date of appl., May 1, 1913.

ON a Fourdrinier machine the wire is held slack and deflected downwards to form a curved surface. Immediately in front of the breast-roll, it is deflected with a steep inclination so that the stuff on the wire acquires a rapid acceleration under the influence of gravity as it moves forward. Further on, when the velocity of the stuff approximates that of the moving wire, the angle of curvature is gradually diminished and ultimately motion is imparted to the stuff wholly by the wire.—J. F. B.

Cork-substitutes; Method of making ——. W. Sanger, Orange, N.J. U.S. Pat. 1,101,965, June 30, 1914; date of appl., April 26, 1912.

A SUBSTITUTE for cork is made by soaking wood in hot water, impregnating it with concentrated hydrochloric acid heated at successively higher temperatures, removing all the acid and boiling the product in a solution of glycerin. —J. F. B.

Process of and apparatus for making sulphite liquor and for blowing acid gases. U.S. Pats. 1,097,781 to 1,097,785. *See* VII.

Process of making sulphite liquor. U.S. Pat. 1,099,565. *See* VII.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Bleaching; Theory of ——. S. H. Higgins. J. Soc. Dyers and Col., 1914, 30, 257—261. (See also this J., 1913, 350, 359, 1064, 1153.)

BROWN linen cloth was submitted to the action of a dilute solution of bleaching powder and the rate of reaction determined by periodic titration of the liquor. The reaction was found to be unimolecular, the speed of reaction being proportional to the active mass of hypochlorite present. The same mathematical relationship held good when either lime water or a small quantity of hydrochloric acid was added to the bath, and again when the experiments were made on indigo dyed on bleached cotton. The difference between chlorine and hypochlorous acid was strikingly shown by the strong bleaching action of a solution of bleaching powder to which boric acid had been added in order to form free hypochlorous acid and the comparatively weak effect of a solution to which the corresponding amount of hydrochloric acid had been added, in which case free chlorine was present. The author concludes that bleaching powder owes its action to the hypochlorous acid in solution, formed by hydrolysis of the hypochlorite, the bleaching being a process of direct oxidation due to the easily removable oxygen of the hypochlorous acid. Hydrolysis would be hindered by addition of hydroxyl ions to the solution, and in agreement with this, addition of sodium carbonate or bicarbonate, lime or caustic soda had the effect of diminishing the bleaching power. The gradual addition of hydrochloric acid on the other hand caused a gradual increase in bleaching power owing to the added hydrions aiding hydrolysis of the hypochlorite. The addition of an excess of caustic soda did not entirely inhibit bleaching action, and it is concluded that there is still an appreciable amount of hydrolysis to free hypochlorous acid even when excess of alkali is present.—J. B.

Mercerisation as judged by the action of caustic soda upon regenerated cellulose. C. Beadle and H. P. Stevens. J. Soc. Dyers and Col., 1914, 30, 244—249.

UP to a certain point increasing concentration of caustic soda causes a gradual increase in the hydration of regenerated cellulose, and after this point a gradual decrease. This maximum advances as the temperature is increased.

The addition of sodium chloride to the lye suppresses these variations. The maximum absorption of caustic soda by the fibre varies in a similar way, taking place at increasing concentrations as the temperature advances. Here the addition of salt causes a general advance in the absorption for each temperature as the concentration increases. Curves for constant concentration and varying temperature show that hydration increases as the temperature decreases, *i.e.*, raising the temperature causes dehydration. This effect is noticed also when caustic soda is added to viscose solutions, small quantities of alkali causing the solution to become thinner whilst stronger alkali salts out the viscose. At 5° C. the maximum hydration of regenerated cellulose is effected by a lye containing 9% NaOH, whilst for the maximum (chemical) mercerisation of cotton, a concentration of 17½% NaOH is required. The difference between the two materials is rather of degree than of kind, however, and may be ascribed to the protecting cuticle of the cotton, which resists the natural swelling of the cellulose substance until the pressure is sufficient to burst the covering. The two materials are alike in that maximum mercerisation corresponds with maximum absorption of alkali; within certain limits the absorption of alkali increases as the temperature decreases; brine has a retarding effect; mercerisation reaches a maximum with a definite concentration of lye; and there is no evidence of a definite sodium-cellulose compound as suggested by Gladstone.—J. B.

Perborate of sodium; Application of —— [in printing]. E. Trepka. Rev. Gén. Mat. Col., 1914, **18**, 193.

THE streaks, produced in printing Logwood Black on tissues, may be completely removed by the use of sodium perborate, without injury to the other colours. The activity of the perborate may be increased by the addition of alkali compounds, preferably sodium phosphate.—B. N.

Malt extract; Determination of ——. W. P. Dreaper. J. Soc Dyers and Col., 1914, **30**, 255—257.

A MODIFICATION of the original method (this J., 1913, 598), the farina solution being padded into the cloth by passing through rollers, and the solution being of such strength that the cloth contains only 2·5% of starch (dry). Errors due to the presence of moisture are avoided by estimating the moisture in the cloth at the time of the assay by drying at 100°—102° C. The treated samples are also dried at this temperature. The treated samples are preferably wrung by hand and not in a cloth. Drying is effected first in a porcelain dish, then in a weighing tube. Blank experiments under these conditions showed no loss of starch. The present procedure is as follows: Pieces of starched cloth (2—3 grms.) are immersed in the malt extract solution of standard strength. The ratio of cloth to solution should be 1 : 200. The time of immersion may vary from 5 to 10 mins., provided it is the same in all cases. The temperature may be the standard one of 40° C. or that used in practice. If the amount of starch removed varies greatly from 1·5—1·8% it will be better to vary the strength of the solution in a second assay. A correction of 0·2% may be made on account of loss of starch due to water alone. The total starch on the cloth is determined by treating it with malt extract at 40° C. for one hour with constant stirring, drying at 100°—102° C. and weighing. Objections to this method on the grounds of variations in conditions, etc., due to the "personal equation," were shown to be invalid, since what is required in the textile industry is simply a comparison of value for starch-removing purposes. Such minor differences were insignificant in view of the extraordinary variations observed between the different extracts at present on the market. It was stated that two samples of extract might easily vary as much as 50% in their rate of action on gelatinised starch in solution or on a fabric.—J. B.

PATENTS.

Bleaching [straw, fibres, etc.]. J. L. Frenay, Luton, Beds. Eng. Pat. 13,753, June 13, 1913.

As a preliminary to bleaching, the material is steeped in a bath containing about 3 lb. of a hydrosulphite compound *e.g.*, "blankit B.A.S.F." and 9 lb. of sodium pyrophosphate per 140 galls. The material is then "cleared" in a bath of dilute sulphuric acid and bleached in the usual manner. —J. F. B.

Posser machines for disinfecting, washing, starching, dyeing, etc. R. C. Fritz, Liverpool. Eng. Pat. 21,979, Sept. 30, 1913.

IN a washing or laundering machine a perforated posser is reciprocated within a vessel so as to compress and release alternately the articles under treatment. A smaller non-perforated element acts on the more central perforations of the posser as an opening and closing disc-valve. The vessel is provided with a curved perforated false-bottom to afford flexibility in the compression-stroke. The posser is operated by a cranked shaft and connecting rods passing through glands in the cover and is connected with the operating rod by a hinge and locking sleeve, so that it may be deflected to give access to the vessel.—J. F. B.

Dyeings; Process for producing fast ——. L. Cassella un Co. G. m. b. H. Ger. Pat. 273,312, March 19, 1913.

FIBRES are dyed, padded, or printed with diazotisabl dyestuffs or with suitable colourless amino-compound which are then diazotised and combined with *m*-diamino benzidine. The dyeings produced are faster to light tha those obtained when β-naphthol, *m*-toluylenediamine, an similar "developers" are used.—T. F. B.

Turkey-red dyeing; Process for ——. J. Graf. Ger. Pa 274,867, Sept. 13, 1912.

THE raw or boiled out goods are passed through a bat of soluble oil or soap and treated with a salt such as a acetate, formate, or lactate, especially of an alkali, alkalin earth, or tin, as well as with a chlorine compound of ti which will fix the soluble fat on the fibre and act as fixing agent for the mordant; the goods are now wrur out and mordanted, without drying, in a strongly bas solution of alum or an aluminium salt, and, again witho drying, dyed and finished in the usual manner. Th process reduces considerably the time necessary for tl treatment, without prejudice to the fastness or beauty the shade.—T. F. B.

Yarn; Arrangement for treating ropes of —— with a liqu contained in a trough. H. Hablützel, Zürich, Switz land. U.S. Pat. 1,100,729, June 23, 1914. Date appl., July 28, 1913.

SEE Fr. Pat. 460,829 of 1913; this J., 1914, 73.—T. F.

Printing plate. J. W. Aylsworth, East Orange, Assig to Condensite Co. of America, Glen Ridge, N.J. U Pat. 1,098,610, June 2, 1914. Date of appl., Oct. 1913.

SEE Eng. Pat. 12,659 of 1911; this J., 1912, 918.—T. F.

Pile-yarn for coloured velvets; Process for produc weighted ——. P. Schmid, Basle, Switzerland. U Pat. 1,102,088, June 30, 1914. Date of appl., Dec. 1911.

SEE Fr. Pat. 435,155 of 1910; this J., 1912, 330.—T. F.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphur in soluble sulphates; An improvement of the bar sulphate determination of —— when sodium salts present. W. A. Turner. Amer. J. Sci., 1914, **38**, 41—

ERROR due to the inclusion of unconverted alkali sulp and of barium chloride in the barium sulphate precipit may be obviated in the case of sodium salts by the previous precipitation of the metal as chloride from a concentrated aqueous solution by the addition of 5 vols. of concentrated hydrochloric acid, and filtration through asbestos. The precipitate is washed with the concentrated acid, the filtrate and washings are evaporated to dryness, dissolved in a small quantity of dilute hydrochloric acid, again filtered to remove traces of silica, then diluted to 350 c.c., and precipitated with barium chloride in the usual way. Since the method is not so successful in presence of potassium salts, sodium peroxide should be substituted for potassium nitrate in those sulphur determinations where a preliminary fusion is necessary.—G. F. M.

Cobalt and nickel; Bromination of —— in the presence of ethyl ether. F. Ducelliez and A. Raynaud. Comptes rend., 1914 **158**, 2002—2003.

Nickel and cobalt both combine readily at the ordinary temperature with dry bromine in the presence of ether, forming $NiBr_2.C_4H_{10}O$ (yellow) and $CoBr_2.C_4H_{10}O$ (green) respectively. These products are readily decomposed by heat yielding the anhydrous bromides.—W. H. P.

Yttrium from yttrium earths; Separation of ——. II. H. C. Holden and C. James. J. Amer. Chem. Soc., 1914, **36**, 1418—1423. (See this J., 1914, 482.)

Fractional precipitation with sodium nitrite is more efficient and cheaper than the phosphate or chromate method for separating yttrium from other rare earth metals, though it is not very effective for separating erbium from yttrium.—L. E.

opper oxide; Catalytic influence of —— on the combination of oxygen and hydrogen. J. Joannis. Comptes rend., 1914, **159**, 64—67. (See also this J., 1914, 254.)

At 300° C. iron does not act as a catalyst towards hydrogen nd oxygen, being simply oxidised. Copper at 200° C. as t 300° C. is first oxidised, the oxide then acting as catalyst. opper oxide at 300° C. brings about practically complete ombination. The tension of the water vapour produced ppears to play an important part in the catalysis.—T. St.

rconium hydroxide; Adsorption by ——. E. Wedekind and H. Rheinboldt. Ber., 1914, **47**, 2142—2150.

elatinous zirconium hydroxide was prepared by treating cold saturated solution of zirconium oxychloride with mmonia, and purifying the precipitate by washing and alysing. The product in the form of a paste possessed nsiderable adsorptive power. Boric and phosphoric ids were adsorbed in accordance with the general lsorption equation, the quantity adsorbed at first increasing with the concentration, but later tending to proach a constant value. In the cases of iodine (in tassium iodide solution) and ammonia, also, the amount sorbed increased with the concentration of the solution, it no indication of approximation to a constant value as observed even when a large excess was used. Coloured lloidal solutions, *e.g.* of ferric hydroxide, molybdenum ue, etc., were rapidly decolorised when shaken with the conium hydroxide paste. Iodine-starch solution was so immediately decolorised; the zirconium hydroxide was loured a deep blue, which was destroyed on heating but -appeared on cooling. Congo Red—a typical colloid estuff—was readily adsorbed by zirconium hydroxide, t Safranine, which is a true salt, was not adsorbed. The ie "Congo-acid" formed a blue adsorption-compound th zirconium hydroxide; on warming, this was converted o the red salt, thus furnishing a case of chemical comation preceded by adsorption (compare Bayliss, this J., 11, 1093).—A. S.

dal cuprous oxide. C. Paal and A. Dexheimer. Ber., 1914, **47**, 2195—2199.

olloidal cupric oxide solution, prepared as described viously (this J., 1906, 534), was converted quantitatively into cuprous oxide on warming with an aqueous solution of hydroxylamine. The cuprous oxide sol was a clear orange to yellowish red liquid when viewed by transmitted light and on exposure to air was oxidised to cupric oxide. When evaporated rapidly in a vacuum it yielded a brittle greenish-yellow to greenish-black solid, much less easily oxidised than the liquid hydrosol, and capable of again yielding the latter on treatment with water. Products containing from 7·58 to 34·17 % Cu_2O were prepared. The cuprous oxide sol was relatively stable towards electrolytes. A solution of the solid product in a small quantity of water remained clear on mixing with several times its volume of alcohol.—A. S.

Colloidal nickelous hydroxide. C. Paal and G. Brunjes. Ber., 1914, **47**, 2200—2202.

Nickelous hydroxide sols were prepared by a method used previously (this J., 1902, 994, 995; 1906, 534) for the preparation of other colloidal hydroxides and oxides of heavy metals, nickel sulphate solution being added to a solution of sodium protalbinate or lysalbinate and the precipitate produced dissolved in dilute sodium hydroxide solution.—A. S.

Reduction of oxides of heavy metals. Catalytic actions of colloidal metals of the platinum group. X. C. Paal. Ber., 1914, **47**, 2202—2216.

Colloidal cupric hydroxide and nickelous hydroxide (see preceding abstract) can be reduced to the corresponding colloidal metals by hydrogen in presence of colloidal palladium as catalyst. Freshly precipitated hydroxides of copper and nickel, suspended in water, can be reduced in a similar manner, but not the hydroxides of cobalt and lead. It is advantageous to add sodium protalbinate to the mixture before reduction, in order to increase the stability of the metal hydrosols produced. When treated in a similar manner ammonium chromate was reduced to colloidal chromium hydroxide, ammonium vanadate to colloidal vanadium trihydroxide, and ammonium molybdate to colloidal molybdenum tetrahydroxide, whilst ammonium tungstate remained unaffected.—A. S.

Non-metallic elements; Positive ions from ——. I. Precipitation of metals from solutions of their salts by yellow phosphorus. R. M. Bird and S. H. Diggs. J. Amer. Chem. Soc., 1914, **36**, 1382—1392.

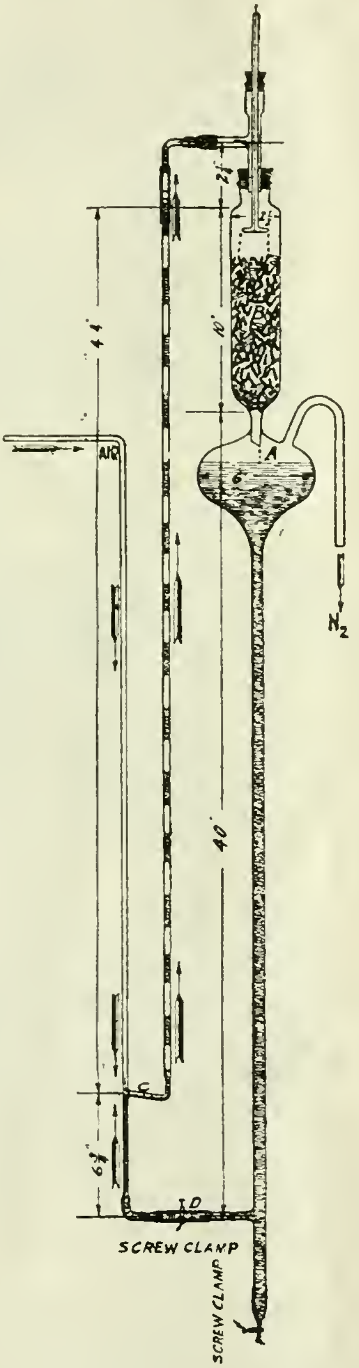
The essential reaction that occurs when phosphorus is immersed in a solution of copper sulphate (cp. Straub, this J., 1903, 1045; Tauchert, this J., 1913, 139) is as follows:— $5CuSO_4+2P+8H_2O=5Cu+5H_2SO_4+2H_3PO_4$. In displacing copper and certain other metals from their salts, phosphorus, like the metallic elements, first passes into solution as a positively charged ion, and the chief distinction between the metals and the so-called non-metals is considered to consist in the tendency of the compounds of the non-metals to be hydrolysed, and ionisation of the products. The E.M.F. between phosphorus and copper appears to be at least 0·35 volt. Amorphous carbon, amorphous boron, crystalline silicon, antimony and arsenic displace silver from solution.—L. E.

Phosphorus; Two new modifications of ——. P. W. Bridgman. J. Amer. Chem. Soc., 1914, **36**, 1344—1363.

Ordinary white phosphorus is converted into another modification—white phosphorus II.—at about —76·9° C. under atmospheric pressure, the change being reversible; the crystalline form of the product is probably hexagonal. A second modification—black phosphorus—is irreversibly formed by heating white phosphorus to 200° C. under a pressure of 12,000 kilos. per sq. cm. Black phosphorus has a density of 2·691, is not spontaneously inflammable, and is a fairly good conductor of heat and electricity. It has a lower vapour pressure and probably a somewhat higher melting point than red phosphorus; red and black phosphorus appear to yield identical liquids when melted. —L. E.

Nitrogen-generator. C. Van Brunt. J. Amer. Chem. Soc., 1914, **36**, 1448—1450.

An apparatus (see fig.) for producing oxygen-free nitrogen from air comprises a reservoir, A, containing a mixture of equal volumes of a saturated solution of commercial ammonium carbonate and ammonia of sp. gr. 0·93. The liquid flows from A at a rate controlled by the screw-clamp, D, and encounters a current of air at the branch, C, which should slope as shown. The fall-tube from A must be long enough to give a pressure at C such that the volume of solution carried up is at least equal to that of the accompanying air without danger of the latter backing up into A. The air-liquid mixture is discharged over the glass bell in the top of B and descends through the column of copper clippings in B. The air now freed from oxygen is dried and freed from ammonia with dilute sulphuric acid. The air current serves to insure the continuous circulation of the liquid through the apparatus.—L. E.



Manganese sulphide and the determination of manganese. Villiers. *See* XXIII.

Patents.

Sulphuric anhydride; Manufacture of——by the contact process.—A. Classen. Ger. Pat. 274,345, Feb. 14, 1913.

Metallic chromium or Cr-Fe, V-Fe, Mo-Fe (50—60% Mo), Si-Mn-Fe, or Si-Al-Mn-Fe alloys, which are resistant to contact-poisons, are used as catalysts at 400°—550° C. —A. S.

Sulphuric acid; Process for obtaining normal sulphate and —— from bisulphate. Metallbank und Metallurgische Ges. A.-G. and H. Klencke. Ger. Pat. 274,873, Aug. 20, 1912.

The bisulphate is decomposed and the resulting normal sulphate melted by the direct action of fire-gases flowing in a direction opposite to that of the charge. The hearth of the reaction chamber is cooled externally so that a relatively thick layer of the charge is solidified thereon, and at one end tap-holes are provided at different heights for drawing off the fused sulphate. The fire-gases enter the chamber at this end, through a vertical channel and strike directly downwards on to the charge; the outlet channel for the highly concentrated sulphuric acid vapours is at the opposite end. The roof of the reaction chamber is provided with longitudinal and transverse projecting ribs to divert the fire-gases from the sides of the chamber towards the middle.—A. S.

Ammonia; Production of mixtures of nitrogen and hydrogen suitable for the manufacture of——. J. Weise. Wiesbaden, and F. Rieche, Oestrich, Assignors to R. Koepp und Co., Chem. Fabr., Oestrich-on-Rhine, Germany. U.S. Pat. 1,098,139, May 26, 1914; date of appl., Jan. 26, 1914.

An alkali, such as caustic soda, is treated with a compressed gaseous mixture containing nitrogen and carbon monoxide, the latter reacting with the alkali to yield formate. The residual nitrogen is maintained unde pressure and is mixed with hydrogen obtained by heatin the formate.—A. S.

Chemical reactions between solid substances and gases high temperatures; Effecting ——. [Production calcium cyanamide or cyanides.] W. P. Dreaper, Londo Eng. Pat. 12,927, June 4, 1913.

In the manufacture of calcium cyanamide or of cyanid by passing nitrogen or ammonia over suitable soli materials, gaseous fuel is burned in surface combustic apparatus, and the heat communicated indirectly, radiation or otherwise, to the solid material. The was combustion gases are utilised as a source of nitrog or for heating boilers.—W. H. C.

Calcium carbide; Process of crushing and grinding —— W. S. Landis, Niagara Falls, Ontario, Assignor American Cyanamid Co., Nashville, Tenn. U.S. P 1,100,582, June 16, 1914; date of appl., June 7, 1913.

To prevent explosions and lessen the "weathering" calcium carbide and the losses incidental thereto, t material is crushed, ground, conveyed, and stored in atmosphere of pure nitrogen at a pressure above that the atmosphere.—A. S.

Magnesium carbonate; Manufacture of basic ——. Silbermann, Rähnitz, Saxony. Eng. Pat. 18,594, A 15, 1913. Under Int. Conv., Aug. 15, 1912.

Solutions of magnesium salts, such as the waste liqu from the manufacture of potassium salts, are precipita at a high temperature (above 40° C.), by solutions of pa carbonated ammonia or of ammonia and ammoni carbonate, the density of the product being regula by adjusting the ratio between free hydroxyl and carb acid of the precipitating medium and by varying temperature and dilution of the solution. The reac products should not remain in contact longer tha necessary.—F. Sodn.

Magnesium chloride present in potash salts; Process removing —— by lixiviation with alcohols. E. Kr geb. Köwing. Ger. Pat. 273,890, April 16, 1 Addition to Ger. Pat. 260,141.

The residue left after removal of the magnesium chlo as described in the chief patent (this J., 1913, 69 heated in a suitable apparatus so as to distil off adh alcohol. The hot material is then transferred dir to the apparatus in which the potassium salts are diss from it.—A. S.

Sulphite liquor ; (1) *Process of and* (2 *and* 5) *apparatus for making* ——. (3) *Process of and* (4) *apparatus for blowing acid gases.* R. B. Wolf, Berlin, N.H., Assignor to Burgess Sulphite Fibre Co., Portland, Me. U.S. Pats. 1,097,781 to 1,097,785, May 26, 1914 ; dates of appl., (1 and 2) Nov. 17, 1909, (3) Jan. 28, 1911, and (4 and 5) July 13, 1911.

(1) GAS containing sulphur dioxide is forced into absorption apparatus in which it is treated on the counter-current principle with a basic liquid, and unabsorbed gas is exposed to an absorbing liquid in the presence of a carbonate, such as limestone. Liquid carrying a base partly in solution, (*e.g.*, milk of lime) is added to the gas as it enters the blower and is subsequently allowed to separate from the gas and passed to the main body of basic liquid, as is also the liquor from the carbonate treatment. (2) Apparatus for producing sulphur dioxide is connected with a cooler and series of absorption tanks fitted with agitators and communicating with a tank for the supply of lime-water to the system on the counter-current principle. A gas blower into which alkali may be introduced is located between the cooler and the absorption system, and means are provided for the production of bisulphite and sulphurous acid by absorption of sulphur dioxide from the excess gas and for conducting the liquors and those separating in the blower, to the lime tank. (3) A neutralising agent added to the gas as it enters the blower, causes an inactive coating to be deposited on the parts of the blower. (4) A blower containing impellers and connected with a tank from which it receives a supply of neutralising agent, is provided with means for the separation of liquid and gas, including a trap with bent foot having an agitator therein. Means are also provided for conducting the liquor to a tank, from which it is pumped back into the trap to secure circulation. (5) Apparatus f the type described under 2 above, includes a tower having a carbonated basic filling, means for introducing absorbing iquid for sulphur dioxide at the top and excess of gas from he absorption system at the bottom of the tower, and or delivering liquor from the tower to the basic liquor tank. —F. SODN.

Sulphite liquor ; Process of making ——. H. K. Moore and R. B. Wolf, Berlin, N.H. U.S. Pat. 1,099,565, June 9, 1914 ; date of appl., Dec. 31, 1913.

HE products of combustion of a sulphur-bearing substance re cooled so as to condense products less volatile than ulphur dioxide, and the residual sulphur dioxide is passed ontinuously through a mixing apparatus, milk of lime, ooled to about 32° F. (0° C.) being passed through the pparatus in the opposite direction. The mixer is cooled o a constant predetermined temperature, and calcium sulphite solution containing a constant proportion f free sulphurous acid, is withdrawn continuously as it rms.—A. S.

odium bisulphite ; Stable crystalline —— *and process of producing same.* H. Howard, Boston, Mass. U.S. Pat. 1,099,177, June 9, 1914 ; date of appl., Sept. 6, 1912.

ULPHUR dioxide is passed through a heated solution ontaining sodium bisulphite until crystals separate. he crystals are removed, dried and cooled. They are e from water of crystallisation, stable, and non-liquescent. The unabsorbed sulphur dioxide is absorbed an alkaline solution, which is subsequently mixed with e mother liquor from the crystals, and the whole again ated with sulphur dioxide.—A. S.

rborates ; Process of dehydrating ——. O. Liebknecht, Frankfort-on-Maine, Germany, Assignor to Roessler and Hasslacher Chem. Co., New York. U.S. Pat. 1,098,740, June 2, 1914 ; date of appl., Nov. 15, 1912.

CRYSTALLISED perborate (such as sodium perborate) heated, preferably at 50°—70° C., in the presence of an ohol.—F. SODN.

Oxidising agents [*sodium perborate*] ; *Stabilised* —— W. E. Kemmerich, Mulheim-on-Rhine, Germany. U.S. Pat. 1,101,449, June 23, 1914 ; date of appl., Jan. 16, 1914.

A SOLUTION containing about 2% of sodium perborate and a small quantity of a stabilising colloid, *e.g.*, 0·1% of gelatin.—A. S.

Perborates ; Manufacture of ——. G. A. Hempel, Ger. Pat. 274,347, April 19, 1913.

SOLUTIONS of borates, such as are obtained for example in the manufacture of borax or boric acid, are treated with gaseous hydrogen peroxide, *e.g.*, with the vapours evolved on distilling per-acids.—A. S.

Phosphoric acid and compounds of the same ; Process of and apparatus for making ——. F. S. Washburn, Nashville, Tenn. U.S. Pat. 1,100,639, June 16, 1914 ; date of appl., Feb. 17, 1914.

A MIXTURE of phosphate rock with silicious and carbonaceous materials is treated in a shaft furnace with a blast of hot air or of enriched air or oxygen, whereby the carbonaceous material is burnt and part of the phosphorus is eliminated. The charge is then transferred to an electric furnace, with addition of a further quantity of silicious and carbonaceous materials, if necessary, and heated to a higher temperature to eliminate the remainder of the phosphorus. The volatilised phosphoric anhydride is condensed.—A. S.

Phosphates, silicates (monazite sand), etc. ; Process for the decomposition of radioactive ——. E. Ebler. Ger. Pat. 274,781, Feb. 28, 1913.

THE phosphate, silicate, or the like is mixed with a metallic reducing agent, *e.g.*, magnesium, calcium, or aluminium, which when ignited, will reduce the substance, without application of external heat. Phosphides, silicides, or the like, readily soluble in dilute acid, are formed, and on treatment with acid most of the phosphorus is removed in the form of hydrogen phosphides, whereby the subsequent extraction of the thorium is greatly facilitated.—A. S.

Arsenate of lead ; Process of making ——. H. H. Dow and E. O. Barstow, Assignors to The Dow Chem. Co., Midland, Mich. U.S. Pat. 1,100,673, June 16, 1914 ; date of appl., June 10, 1911.

A SOLUTION of a soluble acid arsenate (of sodium, for example), to which sodium carbonate or other alkali is added, in amount preferably equivalent to the hydrogen present in the arsenate, is treated with a solution of lead chloride, and the precipitate formed is separated, to obtain a paste of the desired consistence.—F. SODN.

Arsenate of lead ; Method of manufacturing ——. E. O. Barstow, Assignor to The Dow Chem. Co., Midland, Mich. U.S. Pat. 1,100,686, June 16, 1914 ; date of appl., June 10, 1911.

A SOLUBLE arsenate is treated with an acid (such as hydrochloric acid) forming with lead, or other metal concerned, a salt more soluble than the arsenate, and the resulting solution is mixed with lead oxide or other suitable compound.—F. SODN.

Mesothorium and radium ; Process of obtaining salts of —— *from thorium-bearing minerals.* B. Keetman and F. Jost, Assignors to Deutsche Gasglühlicht Akt.-Ges. (Auerges), Berlin, Germany. U.S. Pat. 1,100,743 June 23, 1914 ; date of appl., Feb. 15, 1912.

IN the production of thorium from thorium-bearing minerals, the latter are treated with barium salts and with concentrated sulphuric acid, water is added to form a slimy or muddy product, and this is treated with a further large quantity of water to which is added a quantity of barium salts sufficient to render the radioactive substances (mesothorium and radium) quite insoluble —A. S.

Radium, mesothorium, thorium, and other radioactive substances ; Method of treating sulphates, especially sulphate mixtures containing ——. E. Ebler. Ger. Pat. 274,874, Feb. 28, 1913.

The mixture of sulphates is mixed with calcium hydride, and ignited at one spot, without external application of heat. The reaction proceeds throughout the mass, the sulphates being reduced to sulphides. The reaction product is lixiviated with weak acid solutions, especially dilute hydrochloric acid. The hydrogen produced in the reaction burns outside the mass and protects the sulphides from oxidation.—A. S.

Hypochlorite bleaching liquors from chlorine and alkali solutions ; Continuous production of ——. Deutsche Solvaywerke A.-G. Ger. Pats. 273,795, Jan. 28, 1912, and 274,871, March 16, 1913.

(1) Chlorine gas and alkali solution are introduced continuously into a quantity of hypochlorite bleaching solution, and a corresponding quantity of the solution is continuously withdrawn. (2) An apparatus for carrying out the process consists of a coil of tubing placed in a cooling vessel, chlorine and alkali being introduced to the coil at the lower end and hypochlorite solution withdrawn at the upper end.—A. S.

Oxides and similar compounds of tin ; Process for converting —— into soluble compounds. Chem. Fabr. von der Linde m. b. H. and G. von der Linde. Ger. Pat. 274,045, Oct. 5, 1912.

Oxides or hydroxides of tin are converted into soluble compounds by treatment with stannic or stannous chloride or mixtures of the same. The method is especially suitable for the treatment of so-called "tin pastes" (chiefly oxides and hydroxides of tin) obtained as a by-product in silk weighting processes. For example, 10 kilos. of "tin paste" are heated to 70°—80° C. with 20 kilos. of stannic chloride, an excess of tin added, and the whole evaporated in presence of hydrochloric acid. Impurities are precipitated, and the resulting stannous chloride may be separated from any ferric chloride also present by crystallisation.—A. S.

Chlorate ; Process for removing bromate from ——. Chem. Fabr. Griesheim-Elektron. Ger. Pat. 274,471, March 18, 1913.

A solution of the chlorate is treated with a sulphide of an alkali or alkaline-earth metal, whereby bromate is rapidly decomposed, whilst the chlorate is practically unaffected. The stability of the chlorate is increased by the removal of bromate.—A. S.

Dissolving apparatus for potassium chloride. C. Lührig's Nachf. F. Gröppel. Ger. Pat. 274,473, Dec. 20, 1912.

A tubular filter is suspended in the dissolving vessel so that it is surrounded by the material which is being dissolved ; the latter moves gradually downwards, whilst the solution flows upwards. The filter can be moved vertically up and down, so as to regulate the concentration of the filtered solution drawn off. Or, the filter may be in the form of a jacket enclosing the dissolving vessel.—A.S.

Ozone ; Process for the construction or lining of apparatus, vessels, etc., resistant to ——. Chem. Fabr. Griesheim-Elektron. Ger. Pat. 274,872, June 17, 1913.

Ferrochrome containing at least 25% Cr and little or no carbon is used. It resists the action of ozone and of nitric oxide and peroxide.—A. S.

Nitric acid ; Process of concentrating dilute ——. Salpetersäure-Industrie-Ges. m. b. H., Cologne, Germany. Eng. Pat. 18,113, Aug. 8, 1913. Under Int. Conv., Aug. 24, 1912.

See U.S. Pat. 1,074,287 of 1913; this J., 1913, 1009.—T.F.B.

Distilling acids ; Means for ——. W. Hof, Frankfort on Maine, Germany. U.S. Pat. 1,099,368, June 9, 1914. Date of appl., Sept. 29, 1913.

See Fr. Pat. 463,208 of 1913 ; this J., 1914, 421.—T. F. B.

Hydrosulphites ; Production of anhydrous —— from aqueous hydrosulphite solutions. G. W. Johnson, London. From Chem. Fabr. Griesheim-Elektron, Frankfort on Maine, Germany. Eng. Pat. 14,424, June 21, 1913.

See Fr. Pat. 460,610 of 1913 ; this J., 1914, 76.—T. F. B.

Sulphur and sulphates from sulphites ; Process of producing ——. C. Hanson, Wiesdorf, Assignor to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 1,101,740, June 30, 1914. Date of appl., Jan. 17, 1913.

See Ger. Pat. 264,920 of 1912 ; this J., 1913, 1068.—T. F. B.

Method of and apparatus for electrolysing liquids [brine]. U.S. Pat. 1,100,290. *See* XI.

Gas-analysis apparatus for the treatment of gases with measured quantities of a liquid reagent. Ger. Pat. 273,726. *See* XXIII.

VIII.—GLASS ; CERAMICS.

Tellurium as colouring agent in soda-lime silicate glass P. Fenaroli. Chem.-Zeit., 1914, **38**, 873—874.

Tellurium, like sulphur and selenium (see this J., 1912 1033 ; 1914, 201), acts as a colouring agent in glass onl under reducing conditions, in which case it may be presen as a colloidal solution of the element, causing blue o brown colorations, or as a polytelluride which yields a re glass. In the blue glasses the colloidal particles ar larger than in the brown. The absorption spectrum of th red glasses corresponds to that of aqueous solutions polytellurides, with a characteristic maximum betwee 480 and 490 μμ. Comparing the members of the sulphu family, the author concludes that in combination with a alkali metal their staining power tends from yellow to re with increasing atomic weight ; that they form colloid solutions in glass more easily as the metallic character the element increases, the analogy between selenium ar tellurium being greater in this than between sulphur ar either ; and that none of them colour glass under oxidisi conditions.—H. H. S.

Selenium glasses. O. N. Witt and Fränkel. Sprechsa 1914, **47**, 444—445.

Referring to Fenaroli's work (this J., 1912, 1033 ; 191 201 ; and preceding abstract), a knowledge of the colloid nature of the colouring agent is regarded as less importa than the proportion of selenium introduced to that whi actually stains. The total selenium present was estimat by the amount of iodine it liberated from potassium iodi after the glass had been treated with hydrofluoric ac The chromogenic selenium was estimated colorimetrica by comparison with a colloidal solution obtained reducing selenium dioxide with gelatin and phospho acid. The figures obtained were : selenium introduc 0·0262 ; Se found, 0·021 ; chromogenic Se, 0·0016%- proportion of 100 : 8. Temperature influences the col obtained ; at 620° C. a selenium glass was rendered colo less, but returned to its original tint on cooling. In glas containing potash, the colour tends to brown the m basic the composition. If potash be completely repla by soda, a selenium glass is colourless. The maxim content of selenium in alkali-lime glasses is said to 0·06%, volatilisation taking place above this limit. alkali-lead glasses a much higher content is possible ow to the formation of lead selenide which colours the g dark brown. As selenium in the free state begins volatilise at 120° C. it should be introduced as selenite selenate. In the subsequent discussion, the use of selen as a colouring agent in the ceramic industry was rec mended.—H. H. S.

IX.—BUILDING MATERIALS.

Gypsum ; Dehydration of ——. C. Gaudefroy. Comptes rend., 1914, **158**, 2006—2008.

The second stage in the dehydration of gypsum, viz., the formation of soluble anhydrite from the hemihydrate, $2CaSO_4.H_2O$, is reversible and the reason why widely varying temperatures have been given for the complete dehydration of gypsum, is that the results vary according to the amount of water vapour in the oven. The anhydride can be obtained readily at 110° C. under suitable conditions, but cannot be obtained directly from gypsum without the intermediate formation of hemihydrate. (See also Gallo, this J., 1914, 694).—W. H. P.

Patents.

Brick ; Process for the burning of ——. G. D. Herrold, Fresno, Cal. U.S. Pat. 1,098,625, June 2, 1914 ; date of appl., Oct. 13, 1913.

Bricks, arranged in rows, are subjected to a burning heat, confined by the rows, and the exposed faces of the bricks are glazed by means of a flame which is moved across the faces of the bricks.—W. C. H.

[Refractory] Protective coating ; Article with ——. S. H. Fleming, Assignor to National Carbon Co., Cleveland, Ohio. U.S. Pat. 1,098,794, June 2, 1914 ; date of appl., Oct. 29, 1912.

Refractory articles are coated with a layer of rutile and carbon and heated in the absence of air to change the ayer into titanium carbide and then heated in an atmosphere of nitrogen to form titanium nitride.—W. C. H.

ement-waterproofing compound ; Set-adjusting ——. C. Ellis, Montclair, N.J. U.S. Pat. 1,099,974, June 16, 1914 ; date of appl., Aug. 6, 1912.

A mixture of basic calcium stearate and sodium aluminate n such proportions that the set-retarding effect of the ormer is equalled by the set-accelerating effect of the atter. The stearic acid is approximately 25% of the otal lime content. The composition is substantially free rom fatty grease, excess fat, glycerin and other hygroscopic ubstances ; it can be ground to a fine powder, and when xposed to atmospheric moisture remains in the form of a ne non-caking powder which can be readily mixed with ry cement.—W. C. H.

oloured-cement product and process of producing the same. H. A. Gardner, Washington, D.C. U.S. Pat. 1,100,129, June 16, 1914 ; date of appl., Feb. 18, 1913.

non-hydrous paste consisting of a pigment and an asaponifiable oil, which serves as a protective vehicle, mixed with Portland cement or the like to colour it. —W. C. H.

ement goods ; Process for producing smooth, glossy, or glazed coating on ——. A. Weithaler, Karlsruhe, Germany. U.S. Pat. 1,101,823, June 30, 1914. Date of appl., April 11, 1910.

ee Eng. Pat. 3423 of 1910 ; this J., 1910, 1159.—T. F. B.

X.—METALS ; METALLURGY, INCLUDING ELECTRO-METALLURGY.

on: Effect of titanium on the magnetic properties of ——. K. P. Applegate. Rensselaer Polytech. Inst., New York. Eng. and Sci. Series, No. 5.

he permeability of pure Swedish charcoal iron was creased, and the hysteresis slightly diminished, by small ounts (less than 1%) of titanium ; larger quantities reased the hysteresis loss. When commercial titanium alloys were used in place of pure titanium, metal of inferior magnetic quality was produced. The hysteresis losses of titanium steels were higher than those of the present standard steels, and the maximum induction and the permeability were considerably higher than those of silicon steel (Si 3·5—4·5%) or pure iron.—W. E. F. P.

Steels ; The speed of transformation of —— when heated, and the specific electrical resistance of iron. A. Portevin. Comptes rend., 1914, **159**, 51—53.

Steel bars were heated in salt baths at 750° C. and 900° C. for varying lengths of time, quenched, and the increase in resistance measured. The passing of carbon into solid solution was not instantaneous but took 10 to 20 mins. after the steel had acquired the requisite temperature. Steel with C 0·88% gave a greater increase in resistance on quenching from 900° C. than from 750° C. The specific resistance of pure iron obtained by extrapolation was 9·3 microhms at 20° C.—T. St.

[Steel] Neumann lines ; Formation of ——. (1) Matweieff, (2) A. Portevin and J. Durand. Rev. Mét., 1914, **11**, 766—779.

(1) The formation of "Neumann lines" is considered to be due to twinning induced by friction (scratching) of emery grains along the edges of cleavage planes of crystals during the polishing of the metal. The lines indicate the orientation of the grains and the direction of corrosion, and occur in relief upon the surface of the metal, forming Widmanstaettian figures upon individual grains. (2) The lines are regarded as the result of twinning due to pressure. Micrographic evidence is given to show that, as indicated by Osmond and Cartaud (this J., 1906, 761) the Neumann lamellæ occurring in any given grain are parallel to not more than 6 planes corresponding to the crystalline orientation of the grain itself ; and that the lines are hollows and not ridges as stated by Matweieff.—W. E. F. P.

Nickel steels ; Specific volumes of ——. P. Chevenard. Comptes rend., 1914, **159**, 53—56.

The specific volumes of iron-nickel alloys at 750° C., 0° C. and —273° C. were calculated from dilatation curves obtained for the range —195° C. to 750° C., and the densities determined at the ordinary temperature. The amplitude of the irreversible transformation (peculiar to the alloys with a nickel content lower than that of Fe_2Ni) is proportional to the content of free iron in the alloy.—T. St.

Alloys ; Electrolytic separation of —— and their metallographic and mechanical investigation. V. Iron-nickel alloys deposited at high temperatures from sulphate baths. R. Kremann and R. Maas. Monatsh. Chem., 1914, **35**, 731—753. (See also this J., 1914, 553, 752.)

Experiments were carried out at 75° C. and the results compared with those obtained at ordinary temperatures (this J., 1914, 28). The higher temperature caused an enormous increase in the nickel content of the deposit when the other conditions were not varied. As at ordinary temperature the effect of increasing the nickel content of the electrolyte was first rapidly to increase that of the deposit and then, after a maximum, slowly to diminish it. Potassium oxalate and citric acid both increased the percentage of nickel in the deposit. The effect of citric acid was similar to that of increasing nickel concentration, *i.e.*, it was reversed after a certain point where a maximum was reached. A disadvantage of the higher temperature was that to obtain alloys with less than 70—80% Ni, it was necessary to work with such low Ni concentrations in the electrolyte, that the composition of the deposit was abnormally sensitive to slight variations in the composition of the electrolyte. The high temperature deposits were in general harder and it is concluded that solid solutions were formed to a greater extent, and that hydrogen content is not the predominating factor in the production of hardness. The metallographic investigation again revealed the concentric structure observed with the low-temperature deposits. Electromotive study of the deposits showed that the alloys, when first produced, were in a passive condition; they reached the normal potential only after long immersion in ferrous sulphate solution.—W. H. P.

Alloys; Electrolytic separation of —— and their mechanical and metallographic investigation. IV. The separation of iron-magnesium alloys from aqueous solution. R. Kremann and J. Lorher. Monatsh. Chem., 1914, **35**, 603—634. (See also this J., 1914, 28, 553, 752.)

The electrolytes used contained ferrous sulphate and magnesium chloride in varying concentrations, with in some instances the addition of potassium chloride. The cathode deposit at various current densities from various electrolytes was analysed for iron and magnesium, the difference being attributed to oxygen. The deposits consisted of metallic iron and in certain cases of a solid solution or compound of iron and magnesium, together with ferrous hydroxide and possibly magnesium hydroxide. The evidence for the existence of the combination of iron and magnesium was strengthened by the results of the metallographic investigations and by the measurements of hardness and E.M.F.'s against ferrous and magnesium sulphates. The existence of hydroxides, especially in the deposits from electrolytes poor in magnesium was evident, because the current yield would frequently have been over 100%, if the deposit were assumed to be entirely metallic. In certain cases the deposits were readily oxidised in air with evolution of heat, and were pyrophoric at slightly elevated temperatures. This phenomenon was probably due to the combined effects of ferrous hydroxide, finely divided iron and the iron-magnesium alloy.—W. H. P.

Gold; Contribution to the chemistry of ——. II. Auto-reduction as a factor in the precipitation of metallic gold. V. Lenher. J. Amer. Chem. Soc., 1914, **36**, 1423—1426. (See this J., 1913, 599.)

Gold salts undergo auto-reduction to metallic gold in presence of various metallic peroxides; the metal is also precipitated by manganous salts in neutral or alkaline solution and by cerous hydroxide in alkaline solution, manganese and cerium dioxides being formed in the respective cases. The presence of gold in manganese deposits may be due to two different reactions. In one case free chlorine, produced by the action of an oxidised manganese deposit on a chloride solution containing free acid, dissolves gold; the solution of gold and manganese is stable, whilst acid, but deposits gold and manganese dioxide when neutralised, *e.g.*, with limestone. Or, again, the gold in manganese deposits adjacent to other gold deposits may be formed entirely by auto-reduction of gold from solution by manganese dioxide.—L. E.

Silver; Electrical resistance of pure ——; molten and solid. E. F. Northrup. J. Franklin Inst., 1914, **178**, 85—87. (See also this J., 1914, 141, 264, 357 and 358.)

The curve showing the change of resistance with temperature is very slightly convex toward the temperature axis from 20° C. to the m. pt. In the process of melting the resistance is approximately doubled and then increases in a perfectly linear manner with rise of temperature. The following values may be quoted (microhms per cm^3.): 20° C., 1·659; 60°, 1·900; 960·5° (solid), 8·4; 960·5° (liquid), 16·6; 1340°, 21·01.—W. H. P.

Copper-nickel-manganese alloys. Electrical resistance and temperature coefficient of ——. G. L. Gray. Rensselaer Polytech. Inst., Eng. and Sci. Series No. 4.

The addition of manganese to an alloy of copper and nickel at any concentration usually increases the electrical resistance. The curve of temperature coefficients for these alloys is of the same general shape as the curve of conductivities, and an increase of resistance is usually accompanied by a decrease of temperature coefficient. The curves indicate that the alloy composed of Cu 55, Ni 45, and Mn 15 parts has a specific resistance of about 70 microhms per c.c., and practically no temperature coefficient at 20° C. It is thus a much better resistor than any of those usually employed in precision apparatus.—W. H. P.

Type-metal; Cause of the oxidation of ——. S. Zinberg. Z. angew. Chem., 1914, **27**, 436—437. (See also this J., 1914, 317.)

A type metal containing Pb 80·3, Sb 19·21 and As 0·39%, when placed in river water, was unacted on, but was rapidly attacked by distilled water; after three days 0·6% had been oxidised and corresponding amounts of lead and antimony were found in the water. Experiments with lead shavings gave similar results. It is concluded that water or water vapour is the active agent in the oxidation of type-metal which contains about 80% Pb. Metal containing only about 72% Pb was quite unacted on under the experimental conditions.—J. H. J.

Metals; Influence of time in rapid deformations of ——. G. Charpy and A. Cornu. Comptes rend., 1914, **158**, 1969—1973.

In testing metals by shock, variation in the time of deformation from $\frac{1}{1000}$ to $\frac{1}{100}$ of a second did not produce any appreciable variation in the work absorbed by the rupture.—W. H. P.

Reduction of oxides of heavy metals. Catalytic actions of colloidal metals of the platinum group. X. Paal. *See* VII.

Patents.

[*Iron and steel*]. *Ingots and other castings; Process for casting ——.* F. Melaun, Berlin. Eng. Pat. 8490, Apr. 10, 1913.

Compound ingots are cast by pouring, one after the other, two (or more) different kinds of metal into one vertical mould, the second metal being added before the upper portion of the first has solidified.—W. E. F. P.

Iron and other metals; Manufacture of ——. A. E. Bourcoud, London. Eng. Pat. 12,960, June 4, 1913.

In cyclic processes for the manufacture of iron and other metals (see Eng. Pats. 21,069 of 1905, 21,770 of 1906, and 676 of 1910; this J., 1906, 1152; 1907, 928; 1911, 629), leakage of gas at the heating stoves is obviated by placing the circulator together with the regenerator and desulphuriser entirely between the outlet of the heating stov corresponding to the regenerator and the inlet of th heating stove corresponding to the metallurgical furnace By this arrangement the pressure in the stoves may b kept approximately atmospheric whatever the position o the circulator relatively to the regenerator an desulphuriser.—T. St.

Case-hardening compound. A. O. Blaich, Chicago, Il U.S. Pat. 1,100,008, June 16, 1914; date of app Oct. 18, 1913.

An intimate mixture of charred tan bark 85, a sodiu salt 5, and calcium carbonate 10 parts, obtained b impregnating the bark with an infusion of the oth materials.—T. St.

Armour-plates; Process of treating ——. A. F. Mitche Pittsburgh, and W. H. Jones, Munhall, Pa., Assigno to Carnegie Steel Co., Pittsburgh, Pa. U.S. Pa 1,100,193, June 16, 1914; date of appl., March 2 1910.

The high-carbon surface of a plate in which the carb gradually diminishes from one face, is decarburised to point sufficient to cause it to retain a certain hardne when the plate is hardened. In an example illustrat the carbon content in a 6 in. plate starts from 0·10% the face to a maximum of 0·85% at a depth of ¾ in., fa to 0·41% at 2 in. depth, and then remains constant. —T. St.

[*Manganese-*] *Steel; Method of making ——.* W. Nichols, Chicago Heights, Ill. U.S. Pat. 1,100,9 June 23, 1914; date of appl., Feb. 25, 1914.

Manganese-steel is made by mixing in a comm receptacle decarbonised iron 55, manganese steel scr containing Mn about 12%, 37, and 80% ferromanganese 8 parts. The components are melted separately, and heated, the iron to about 1650° C., the steel scrap to about 1400° C., and the ferromanganese to about 1350° C., just prior to mixing.—T. St.

Ferromanganese; Melting ——. E. Humbert, Chicago, Ill. U.S. Pat. 1,101,551, June 30, 1914; date of appl., July 18, 1913.

Ferromanganese is maintained molten in an electric furnace of the electrode type, solid alloy being added to replace metal, as this is tapped. A comparatively thick layer of carbonaceous material on the bath and surrounding the ends of the electrodes, serves to avoid excessive variations in voltage when the surface is agitated, to protect the metal from the air, and, by its partial consumption, keep up the temperature of the bath.—T. St.

[*Iron*]. *Metal alloys; Producing* ——. L. Goldmerstein, New York. U.S. Pat. 1,098,346, May 26, 1914; date of appl., Jan. 17, 1913.

To a bath of molten metal (iron) containing an impurity, a metallic fluoride is added which is dissociated at the temperature of the bath; the impurity is thus removed (as fluoride) and an alloy of the two metals produced.
—W. E. F. P.

Copper; Process for obaining adhesive coatings of —— upon iron and steel. S. O. Cowper-Coles, London. Eng. Pat. 25,393, Nov. 6, 1913.

Iron or steel is cleansed, rendered passive by dipping in oncentrated nitric acid or by other means, washed, and ransferred to an electrolytic copper-depositing tank in which the anode and cathode are already connected up in the electric circuit. The electrolyte is prepared by heating an aqueous solution of potassium cyanide nearly to boiling, dding copper sulphite, heating the solution to boiling, llowing to cool, filtering and diluting. An alternative lectrolyte is composed of copper carbonate dissolved n potassium cyanide solution to which sodium bisulphite s added. The copper is deposited at about 60° C., with a current density of about 3 amps. per sq. ft. of cathode urface, and the steel or iron is subsequently removed, horoughly washed, and immediately transferred to a opper sulphate depositing tank in which it is allowed to emain until the copper coating has attained the desired hickness.—T. St.

Zinc-lead ores; Treatment of ——.] *Solutions; Apparatus for making and filtering* ——, *applicable in the extraction of metals from ores and for like purposes.* P. C. C. Isherwood, Bushey Heath, Herts. Eng. Pat. 6413, Mar. 15, 1913.

A closed, rotary cylinder is divided by a longitudinal artition into two similar compartments each having a lter-plate parallel to the partition. Openings are proided in the cylinder wall for charging and discharging each ompartment, and for removing the solution from the paces between the filter-plates; and provision is made or introducing high-pressure steam into each compartment.—W. E. F. P.

inc blende and other metalliferous constituents; Separation of —— from ore concentrates and slimes by flotation or granulation. E. J. Horwood, Broken Hill, New South Wales. Eng. Pat. 28,604, Dec. 11, 1913. Under Int. Conv., Dec. 12, 1912.

RE or sulphide material is prepared for the roasting peration which renders sulphides other than zinc sulphide ncapable of flotation (Eng. Pat. 1789 of 1909; this J., 910, 285, and Fr. Pat. 399,272 of 1909; this J., 1909, 2) by washing thoroughly with clean water to remove l soluble salts. This treatment results in reduced xidation of zinc during roasting, the possibility of otation at a lower temperature, and cleaner separation zinc from the other minerals present.—T. St.

Sulphides; Process for the separation of metallic —— from gangue and apparatus therefor. L. Bradford, Broken Hill, New South Wales, Assignor to Minerals Separation Ltd., London. U.S. Pat. 1,101,506, June 23, 1914; date of appl., March 11, 1912.

The ground ore is mixed with slightly acidulated water to form a flowing pulp, heated, and treated with a further quantity of acid to cause gas to be evolved. Air is then introduced and the whole subjected to violent agitation; the pulp is run off and the floating material separated.
—T. St.

Sulphide ores; Flotation process for the concentration of —— by means of oil and nascent gases. Tellus A.-G. für Bergbau und Hüttenindustrie. Ger. Pat. 274,002, March 2, 1913. Addition to Ger. Pat 273,266 (this J., 1914, 698).

The mixture of ore pulp and oil, etc., is fed on to a distributing cone which delivers it on to the surface of a mass of water. The distributor is in the form of a double cone, the portion tapering downwards being below the surface of the water and having a central opening communicating with radial passages through which dilute acid is delivered under pressure just below the surface of the water. In a modified form the acid-distributing device is separate from the distributing cone for the ore pulp.—A. S.

Lead, zinc, and copper ores; Preparation of very finely-divided —— for an oil-flotation process. K. A. H. Wolf. Ger. Pat. 274,530, Nov. 5, 1911.

The very finely ground ore is intimately mixed with an equal weight of water in a vessel provided with a mechanical agitator to which also compressed air is supplied. The ore pulp is treated with dilute sulphuric acid in the known manner, then intimately mixed with oil, and transferred to spitzkasten.—A. S.

Tungsten metal bodies; Manufacture of ——. C. Gladitz, London. Eng. Pat. 12,421, May 28, 1913.

Fluffy tungsten powder (see Eng. Pat. 27,859 of 1912; this J., 1914, 204) is mixed with a small quantity (5% to 25%) of tungsten powder of larger grain, and the mixture compressed into bars which are heated to 2650° C. by an alternating current, a liquid resistance being used so that the temperature can be raised and lowered gradually. The bars so formed are extremely ductile and can, by cold hammering, be reduced by 10% of their section. The larger crystalline variety of tungsten, the function of which is to provide nuclei for the growth of larger crystals in the compressed bar, is formed from the fluffy variety by heating or compressing or by simultaneously compressing and heating, then grinding and sifting to obtain clusters of a size suitable for use as nuclei.—T. St.

Ores; Dressing of ——. C. Vautin, London. Eng. Pats. 14,428 and 15,304, June 21, and July 2, 1913.

Crushed ore having particles of substantially uniform size is fed into a vertical cylindrical vessel with a conical bottom. Fluid such as air or water is introduced by tangential injectors so that it rotates rapidly within the cylinder about the vertical axis. The heavier particles of the ore are thus caused to move towards the centre, and are run off by a pipe at the bottom. The lighter particles are drawn off by suction through a number of vertical tubes arranged concentrically with and near the cylinder wall.—T. St.

Copper or nickel; Compound for use in welding joints in ——. C. Canzler and R. Samesreuther, Düren, Germany. Eng. Pat. 21,012, Sept. 17, 1913. Under Int. Conv., Sept. 30, 1912.

Copper containing P 0·04 to 0·5% is combined with 2 to 5% of Ag, Cd, or Bi, or more than one of these metals, and the compound in the form of wire is used for welding copper or nickel joints.—T. St

Copper ; Method of welding ——. E. E. Reigle. Assignor to J. Zajic, Baltimore, Md. U.S. Pat. 1,098,404, June 2, 1914 ; date of appl., March 10, 1914.

The metal is kept for 2 hours in a boiling solution of potassium chlorate and then welded as usual.—W. E. F. P.

Copper ; Process for separating —— from nickel and cobalt. V. Hybinette, Fredericktown, Mo. U.S. Pat. 1,098,443, June 2, 1914 ; date of appl., July 11, 1907. Renewed Nov. 2, 1911.

Sulphide ores or concentration products are roasted and subjected to magnetic separation. The concentrates, after having part of the sulphur removed, if necessary, by roasting, are smelted into a matte, which is then roasted, and leached with dilute sulphuric acid, whereby a solution is obtained containing principally copper.—T. St.

[*Copper*] *Metalliferous materials ; Art of treating* ——. H. B. Hovland, Duluth, and G. B. Frankforter, Minneapolis, Minn. U.S. Pat. 1,098,668, June 2, 1914 ; date of appl., Dec. 12, 1913.

Dry copper-containing material is treated with dry hydrogen sulphide without the application of heat.—T. St.

[*Copper*] *Smelting and briquetting process.* B. T. Colley, Raneagua, Chile. U.S. Pat. 1,098,883, June 2, 1914 ; date of appl., Dec. 15, 1911.

Finely-divided, pyritic copper ore is roasted to convert FeS_2 into FeS, mixed with plaster of Paris (5%), and the mixture briquetted and smelted as usual.—W. E. F. P.

Bismuth ; Proces for separating —— from copper. W. Thum, Hammond, Ind., Assignor to United States Metals Refining Co., New York. U.S. Pat. 1,098,854, June 2, 1914 ; date of appl., Sept. 17, 1910.

The mixture of bismuth and copper is oxidised, reduced to a fine state, and smelted with an excess of carbon and sodium sulphate. The resulting crude bismuth and copper matte are separated, and the former oxidised and again smelted with a suitable sulphur compound.—T. St.

Furnace for treating molten metals ; Single- or multi-phase electric [*induction*] ——. P. Lescure, Dombrowa, Russia. Eng. Pat. 3291, Feb. 7, 1914. Under Int. Conv., Feb. 7, 1913.

The secondary winding, constituted by the metal to be treated, is formed of several spirals surrounding the magnetic current circuit, and is also prolonged as an outer circuit in the form of a vertical passage, the latter being provided with a tapping hole. Each of the phases has a superposed chamber containing the metal, one end of the spiral and the vertical passage being in communication with the chamber, and the latter is furnished with a cover so that the furnace may be fed and the contents stirred. The secondary channel is arranged in the refractory material of the furnace, one half of the channel being formed of easily replaced tiles, which may or may not be provided with ribs for dividing the channel forming the winding into one or several longitudinal channels.—B. N.

Furnace ; Electrical —— for the reduction of copper and other ores. W. H. Hampton, New York, Assignor to The Conley Electric Furnace Co., Wilmington, Del. U.S. Pat. 1,100,972, June 23, 1914 ; date of appl., Oct. 7, 1913.

The furnace comprises an upper shaft portion and a hearth, and between the two are several small circular shafts having hopper-like entrances ; the combined area of these shafts is materially smaller than that of the common shaft above. Electrical resistance heaters are disposed in the walls of the large and smaller shafts.—B. N.

Furnace ; Ore-roasting ——. W. F. Murphy, Iowa City. U.S. Pat. 1,099,309, June 9, 1914 ; date of appl., Feb. 11, 1911.

The base or hearth of the roasting chamber is formed by the upper part of an endless conveyor to which the ore is supplied by a similar device disposed at a higher level in the apparatus.—W. E. F. P.

Rabbles and rabble-arm for metallurgical furnaces. U. Wedge, Ardmore, Pa. U.S. Pat. 1,100,461, June 16, 1914, date of appl., Dec. 27, 1912.

A series of chambered rabbles project from the under side of a hollow rabble arm, and are connected by a series of chambered ribs crossing over the back of the arm. The outermost rabble communicates with the interior of the arm, and the innermost rabble with a discharge outlet. Circulating water thus passes outwards through the arm and back through the rabbles.—T. St.

Stirring device for mechanical roasting furnaces. Metallbank und Metallurgische Ges. A.-G. Ger. Pat. 273,942, April 8, 1913. Addition to Ger Pat. 268,602.

The stirrer-arms are fixed to the axis by bolts. The bolt passes through a tubular member fixed inside the arm and is provided with a collar fitting in an enlarged portion of the tube, and held therein by a cap screwed on over the open end of the tube. When the bolt is screwed in one direction, the collar presses against this cap and holds the stirrer-arm in place, whilst when screwed in the other direction, the collar presses against the opposite end of the enlarged portion of the tube and forces the stirrer-arm off its seating.—A. S.

Alkali metals and alkali metal compounds ; Electrolytic manufacture of ——. E. A. Ashcroft, London. Eng. Pat. 10,980, May 4, 1914.

The electrolyte in the second cell consists of a fused mixture of alkali hydroxide and alkali cyanide, with o without other salts (see Eng. Pats. 1001, 1002, 1003, 100 of 1912 and 25,144 of 1913 ; this J., 1913, 199).—B. N.

[*Gold and silver*]. *Ores ; Process for treating cyanidabl —— containing deleterious slimes.* W. E. Darrew Sutter Creek, Cal. U.S. Pat. 1,098,020, May 26, 1914 date of appl., Mar. 11, 1914.

The slimes are separated from the ore and "treated t remove graphite and other deleterious colloidal sub stances."—W. E. F. P.

Alloy. C. P. Van Gundy, Catonsville. Md. U.S. Pat 1,098,137, May 26, 1914 ; date of appl., Dec. 8, 1913.

An alloy of Al 85—87 (preferably 86·5), Zn 9—11 (9·7 Pb 2—4 (2·5), and Cu 1—3 (1·3)%.—A. S.

Aluminium alloy. W. A. McAdams, Bay Shore, N.Y U.S. Pat. 1,099,561, June 9, 1914 ; date of appl Feb. 11, 1913.

An alloy of Al 100, Cu 5, and Ag 2 parts.—A. S.

Alloy. R. R. Graf, Highlandtown, Md., Assignor t F. E. Welsh, jun., Baltimore, Md. U.S. Pat. 1,101,53 June 30, 1914 ; date of appl., Nov. 5, 1913.

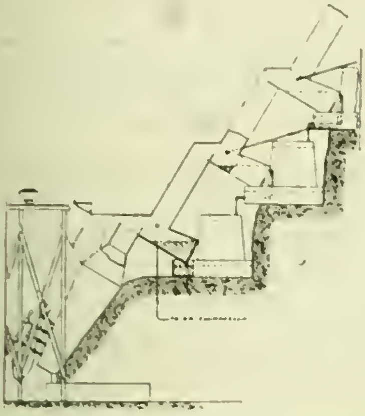
An alloy of Pt 45, Au 15, Ag 25, and Cu 15%.—T. St.

Vanadium and uranium minerals ; Process for treati so-called carnotite and associated and similar —— H. N. McCoy, Chicago, Ill. U.S. Pat. 1,098,28 May 26, 1914 ; date of appl., Mar. 16, 1914.

The finely divided ore is heated with sulphuric ac to about 300° C. to produce a mass which solidifies cooling ; the latter is leached with water to recov vanadium and uranium, and the insoluble resid "treated for the concentration of its radium content."
—W. E. F. P.

Smelter-fumes ; Device for treating ——. O. V. Blom, Fresno, Cal. U.S. Pat. 1,098,611, June 2, 1914 ; date of appl., Apr. 7, 1913.

An inclined conduit (see fig.) arranged in steps, and having upon its under side a number of projecting receptacles one at the base of each step). each of which communicates ith a separate adjacent vessel by means of a door in the ower, and a pipe at the upper, part of the end wall. —W. E. F. P.



letals ; Process of reducing and separating —— from their ores. J. M. McCormack, Assignor to G. A. McCormack, D. R. Williams, J. Constable, and F. L. Brown, Reno, Nev. U.S. Pat. 1,099,388, June 9, 1914 ; date of appl., April 22, 1913.

ARBONATE, oxide and sulphide ores are broken up and bjected to the direct contact of a single flame of a mperature sufficient to reduce and cause incipient sion of the ores, whereby the contained metals are mpletely reduced to commercially pure metal.—T. St.

lectrometallurgical products : Treating ——. F. J. Tone, Assignor to The Carborundum Co., Niagara Falls, N.Y. U.S. Pat. 1,099,674, June 9, 1914 ; date of appl., Sept. 17, 1910.

HE carbides and silicides, existing as impurities in elecometallurgical products used for abrasive or refractory rposes, are removed by treating the products with lorine under the action of heat and pressure.—B. N.

tals or alloys ; Process of casting from volatilisable ——. W. D. Hall, Oak Park, Ill. U.S. Pat. 1,100,132, June 16, 1914 ; date of appl., July 9, 1913.

casting volatilisable metals or alloys in refractory permeable moulds. the molten metal is introduced into e mould at a point substantially level with the highest int of the casting chamber. Gases due to volatilisation thus at all times liberated in the unfilled portion of the ting chamber, and being able to escape, do not cause w-holes or other imperfections in the casting.—T. St.

tal-precipitating device. F. A. Ross, Spokane, Wash., Assignor to Chalmers and Williams, Inc., Chicago Heights, Ill. U.S. Pat. 1,101,569, June 30, 1914 ; ate of appl., Sept. 4, 1913.

PERFORATED cylinder mounted on a hollow perforated ft revolves within a tank, the cylinder being partly d with loose metallic precipitant in a finely divided te. The metal-bearing solution enters the tank below bottom of the cylinder, and passes out through the tral shaft.—T. St.

s rich in alkaline-earth carbonates ; Extraction of —— h bisulphate solutions. W. Günther. Ger. Pat. .426, Oct. 4, 1912.

round ore is treated with a slight excess of bisulphate tion, and the mixture agitated to facilitate evolution of the liberated carbon dioxide. The liquor is drawn off and may be brought into contact with a fresh charge of ore to neutralise the excess of acid. The dissolved metals are precipitated in any suitable manner, and the bisulphate solution regenerated by addition of sulphuric acid or of normal sulphate as required. Various modifications to suit particular kinds of ores and according to the final products desired are described.—A. S.

Metal alloys : Production of ——. L. Goldmerstein, New York. Eng. Pat. 7103, March 25, 1913.

See U.S. Pat. 1,098,346 of 1914 ; preceding.—T. F. B.

Metals, particularly aluminium ; Process for the protection and ornamentation of ——. J. Tronel, Berlin. Eng. Pat. 11,717, May 20, 1913. Under Int. Conv., May 20, 1912.

See Ger. Pat. 273,498 of 1912 ; this J , 1914, 700.—T. F. B.

Tungsten and tungsten alloy ; Process of producing filaments or wire of ——. E. A. Krüger, Altmark, Germany. Eng. Pat. 16,066, July 11, 1913.

See Fr. Pat. 460,556 of 1913 ; this J., 1914, 69.—T. F. B.

Slag ; Utilisation of the heat of ——. C. Semmler, Wiesbaden, Germany. Eng. Pat. 22,874, Oct. 10, 1913.

See Fr. Pat. 463,298 of 1913 ; this J., 1914, 426.—T. F. B.

Copper ; Process for welding ——. H. Suzuki, Shiba-Ku, Tokyo. Eng. Pat. 23,026, Oct. 11, 1913.

See Fr. Pat. 461,688 of 1913 ; this J., 1914, 205.—T. F. B.

Furnaces : Electric —— [for melting ferro-alloys, etc.]. Soc Electro-Métallurgique de St. Béron, Lyons, France. Eng. Pat. 3835, Feb. 13, 1914. Under Int. Conv., Feb. 20, 1913.

See Fr. Pat. 466,116 of 1913 ; this J., 1914, 599.—T. F. B.

Metal ; Extraction of a —— by electrolytic exhaustion of a solution of a salt of this metal. N. H. M. Dekker, Paris. U.S. Pat. 1,101,620, June 30, 1914. Date of appl., May 14, 1913.

See Eng. Pat. 17,836 of 1912 ; this J., 1913, 662.—T. F. B.

Apparatus for clarifying liquids and thickening pulps. U.S. Pat. 1,098,812. *See* I.

Apparatus for thickening pulps. U.S. Pat. 1,099,396. *See* I.

Process of and apparatus for filtering slimes. U.S. Pats. 1,100,217 to 1,100,223. *See* I.

Construction or lining of apparatus, etc., resistant to ozone. Ger. Pat. 274,872. *See* VII.

XI.—ELECTRO-CHEMISTRY.

Patents.

Specific gravity of acid in cells with sealed covers ; Apparatus for testing the ——. The D.P. Battery Co., Ltd. and T. C Elliott, Bakewell, Derbyshire. Eng. Pat. 13,480, June 11, 1913.

A glass tube, containing a hydrometer, is connected below by a rubber tube to the cell. and fitting telescopically and tightly around the tube is a sliding concentric ebonite tube provided above with a vent hole. By closing the latter and withdrawing the ebonite tube, a partial vacuum is formed within which causes the acid to flow into the glass tube, so that the specific gravity of the liquid may be read off.—B. N

Electrode mass for alkaline accumulators; Restoring the activity of a positive ——. Svenska Ackumulator Aktiebolaget Jungner, Stockholm, Sweden. Eng. Pat. 72, Jan. 1, 1914. Under Int. Conv., Jan. 16, 1913.

The activity of nickel oxides may be restored by withdrawing the electrolyte, and adding a heated solution of a reducing agent, such as sugar, or a mixture of glycerin and alcohol. After some hours, the liquid is withdrawn, and the cell is charged after replacing the electrolyte. —B. N.

Electrodes; Treating ——. C. P. Landreth, Philadelphia, Pa. U.S. Pat. 1,099,654, June 9, 1914; date of appl., Feb. 21, 1913.

A mass of material, immersed in the electrolyte, is electropositive with respect to a number of metallic positive and negative electrodes, but is normally out of the electric circuit. Switching mechanism is provided for breaking the connection of the source of energy with the electrodes, and for connecting the latter with the mass of material outside of the electrolyte.—B. N.

Electrolysing liquids [brine]; Method of and apparatus for ——. H. H. Dow, Assignor to The Dow Chemical Co., Midland, Mich. U.S. Pat. 1,100,290, June 16, 1914; date of appl., Dec. 30, 1912.

Natural brine, containing alkaline-earth and iron chlorides, is electrolysed for the production of chlorine and alkali, the latter precipitating the hydroxides of the bases named to form a diaphragm between the electrodes. A partition, between the electrodes, depends below the normal level of the electrolyte, and the diaphragm collects below the cathode, extending from the partition to the adjacent wall of the cell. Suitable connections supply electrolyte above the level of the diaphragm, but the cathode is maintained in a solution substantially free from alkaline-earth and iron chlorides.—B. N.

Electrolytic process of and apparatus for producing compounds. E. A. Byrnes, Washington, D.C. U.S. Pat. 1,102,209, June 30, 1914; date of appl., July 25, 1903. Renewed March 9, 1910.

Ions of adjacent electrolytes are discharged upon intermediate electrodes, in the presence of a substance capable of oxidation by the anion and reduction by the cathion. The electrolytic products are combined, the resulting compound being separated from both electrolytes and washed out from the cell.—B. N.

Electrode material for vapour electric apparatus. R. P. Jackson, Edgewood Park, Pa., Assignor to Westinghouse Electric and Manufacturing Co., Pa. U.S. Pat. 1,099,375, June 9, 1914; date of appl., July 17, 1912.

The volatile electrode is composed of mercury, with not more than 0·2% Pb.—B. N.

Furnace; Electrical induction ——. K. A. F. Hiorth, Christiania, Norway. U.S. Pat. 1,099,440, June 9, 1914; date of appl., Oct. 8, 1913.

The channel, forming the melting bath, has a central portion extending through the magnetic core of the furnace, and branches extending outside the core. Two conductor coils, embracing individual sides of the core, lie in a plane near the top of the channel between the central portion and the branches, each coil having a flattened portion on the inside to prevent overlapping, and the remaining part forming approximately three-quarters of a circle. Two other conductor coils, each embracing one side of the core, lie wholly below the plane of the bottom of the channel, and are greater in diameter than the upper coils, so that the lower part of the outer branches of the channel lies on the surface of an imaginary cone passing through the conductor parts of the upper and lower coils.—B. N.

Electrode. Electric furnace. F. J. Machalske, Assignor to American Ferroelectride Corporation, Plattsburg, N.Y. U.S. Pats. 1,099,558 and 1,099,559, June 9, 1914; date of appl., June 27, 1913.

(1) The electrode, for smelting purposes, consists principally of a refractory magnesium compound of relatively high conductivity when heated, and several graphite rods embedded in it lengthwise to form conducting paths. (2) The bottom and lower portions of the side walls of the furnace are lined with artificial graphitic carbon, and the adjacent parts of the walls with a magnesite lining, taps being placed at the top of the graphitic lining.—B. N.

Furnace; Electric ——. W. F. McNabb, Pittsburgh, Pa. U.S. Pat. 1,100,191, June 16, 1914; date of appl., Sept. 15, 1913.

The furnace comprises a crucible chamber having a bottom in the form of an arched wall, forming an arc chamber below with a concave roof, in which an arc is produced between a pair of electrodes.—B. N.

Furnace; Electric ——. J. W. Brown, Lakewood, Ohio, Assignor to National Carbon Co., Cleveland, Ohio. U.S. Pat. 1,100,709, June 23, 1914; date of appl., Jan. 8, 1912.

The furnace, of the continuous operating type, is provided with horizontal heating electrodes, spaced apart so that the charge may be fed between them for treatment. The treated charge is removed below the electrodes, by an arrangement spaced at such a distance from them that the whole of the descending charge is inclined within lines of movement having a slope greater than 70°.—B. N.

Furnaces; Contact for electric ——. *Door for electri furnaces. Electric furnace.* F. T. Snyder, Oak Park Ill. U.S. Pats. 1,100,993 to 1,100,995, June 23, 1914 date of appl., Oct. 28, 1912.

(1) The contact holder comprises a metallic block with a enlarged lower end, through which a circular hole, provide with a continuous spiral groove, extends, forming a wate chamber in which a whirling motion is given to the liquid The ends of the hole are threaded to receive inlet an outlet pipes. (2) The furnace has an opening taperin inwards, which is closed by a tapering refractory plu secured to an outer frame. The hinge for the door con prises a pivoted post attached to two arms, betwee which the frame is pivoted, so that the door may rotated upon a vertical axis independent of the ax of the hinge. (3) The domed roof of the furnace is con posed of truncated pyramids of silica bricks keyed togeth in more than one direction, and is supported by a ske back of concrete resting upon a metallic ring, the upp end of the circular wall of the smelting chamber constituti an abutment. The crown portion of the roof is square cross-section, and is formed of several tapering bric having their converging corners grooved to provide electrode opening.—B. N.

Insulating coating and method of forming and applyi the same. H. B. Holmes, Park Ridge, and J. W. Harr Wilmette, Ill., Assignors to Western Electric Co. U. Pat. 1,101,281, June 23, 1914; date of appl., Nov. 1905.

The coating comprises a solid hydrocarbon, such ozokerite and asphaltum, and a non-drying vegetable such as castor oil, subjected to destructive distillati —B. N.

Furnaces; Electric ——. I. Rennerfelt, Stockholm. E Pat. 24,850, Oct. 31, 1913. Under Int. Conv., Dec. 1912.

See Fr. Pat. 466,291 of 1913; this J., 1914, 599.—T F.

XII.—FATS; OILS; WAXES.

il and manure; Utilisation of fish and marine animals as sources of ——. Part I. Oils. Bull. Imp. Inst., 1914, **12**, 251—273.

DESCRIPTION of the sources and manufacture of whale ils, cod-liver oil, menhaden oil and of other fish oils f lesser importance, such as shark and dog-fish oils. he characters and uses of the various oils are also dealt ith, and some information is given about whale-bone and mbergris.—R. G. P.

conut oil; Refining —— with concentrated sulphuric acid. J. Pavlicek. Seifensieder-Zeit., 1914, **41**, 566—568. Chem. Zentr., 1914, **2**, 175.

XPERIMENTS were made with quantities of acid ranging om 0·5—2% of the crude oil, but satisfactory results were tained only when not more than 1% was used. The l was partially bleached, and gelatinous and albuminous bstances, and the alkaloid causing the unpleasant taste of e oil, were removed by the treatment. The treated l was more readily deodorised and then showed little ndency to become rancid. As the quantity of sulphuric d used was increased, the acid value of the oil rose d the content of volatile acids fell. No sulphuric acid uld be detected in the ash of the refined oil, and it is ggested that the reactions which take place are :—

$$C_{17}H_{33}.COOH+H_2SO_4=C_{17}H_{34}(OSO_2OH)COOH;$$
$$C_{17}H_{34}(OSO_2OH)COOH+H_2O=C_{17}H_{34}(OH)COOH+H_2SO_4.$$

—A. S.

ls; Hydrogenation of —— by the aid of nickel oxides and reduced nickel. W. Ipatiew. J. Russ. Phys.-Chem. Ges., 1914, **46**, 302—311. Chem. Zentr., 1914, **2**, 92—93.

REPLY to certain statements of Bedford and Erdmann s J., 1913, 611). By working under pressure hydro- ation can be effected at a lower temperature than when erating at atmospheric pressure. If the catalyst be imately mixed with the material under treatment, purified fats can be hydrogenated under pressure; the l pressure in the apparatus may be 7—8 atmospheres. ery high reaction velocity can be attained with specially uced nickel or by the combined action of different alysts, and the catalyst may be used several times in cession.—A. S.

ymes [lipase] of Chelidonium seeds. II. K. Bournot. Biochem. Zeits., 1914, **65**, 140—157. (See this J., 1913, 58.)

E whole seeds exhibit no lipolytic activity; the activity the powdered seeds increases with the fineness of the der. The expressed and filtered oil from the seeds is ctive, though the oil obtained by digestion of the ground ds with petroleum ether at the ordinary temperature, omewhat active. An active preparation of the lipase st obtained by extracting the ground seeds for 2—3 rs in a Soxhlet apparatus with ether or petroleum er, and sifting the residue through a fine hair sieve; urther ground, the sifted product becomes less active. lipase has considerable synthetic power. Mixtures leic acid and most of the monohydric primary alcohols esterified to the extent of about 90%; the secondary hols are esterified less readily, and the tertiary still less or not at all. Di- and trihydric alcohols are less readily esterified than monohydric alcohols. If a mixture of equal parts of oleic acid and glycerin with 5% of water is subjected to the action of the enzyme for 24 hours at 35° C., about 75% of the acid is combined. Most of the acids of the type, $R.CH_2.COOH$, are readily esterified but those of the types, $R_2.CH.COOH$, and $R_3.C.COOH$ (excepting isobutyric and benzoic acids), are not esterified; the rate of esterification increases with the number of carbon atoms in the acid.—L. E.

Fatty acids; Melting and solidifying points of mixtures of —— and the use of these points to determine the composition of such mixtures. E. Twitchell. J. Ind. Eng. Chem., 1914, **6**, 564—569.

THE molecular weights of the fatty acids present in most fats do not differ very widely and hence, in accordance with the law of equal depression of freezing point for equal molecular proportions, when a fatty acid is added in a definite proportion (up to 20%) to another fatty acid, the melting point of the solvent acid is depressed by an amount depending on the quantity of added acid but practically independent of its kind. A method of determining the composition of mixtures of fatty acids may be based on this fact, a definite proportion of the unknown mixture being added to a pure fatty acid and the depression of melting point observed. Pure stearic, palmitic, and behenic acids were prepared from hydrogenated maize oil, myrtle wax, and hydrogenated menhaden oil respectively by fractionally distilling the mixed fatty acids with steam and then recrystallising from petroleum ether and alcohol. Oleic acid free from solid fatty acids was prepared by the lead soap method. The characters of the acids were as follows :—stearic acid: solidif. pt. 69·04°, m. pt. 69·30° C., combining weight 284; palmitic acid: solidif. pt. 62·14°, m. pt. 62·44° C., combining weight 255·3; behenic acid: solidif. pt. 79·59°, m. pt. 79·99° C., combining weight 340·9; oleic acid: iodine value 92·96. The depression of the melting point of either stearic, palmitic, or behenic acid by the addition of 10% of one of the other acids or of a mixture of the same varied from 1·91 to 2·17; and by 20%, from 3·93 to 4·54. In applying the method outlined above to the examination of the fatty acids of cottonseed and menhaden oils, definite quantities of the mixed fatty acids, the solid fatty acids (separated by the lead-soap ether method) and the fatty acids from the hydrogenated oil were added to stearic acid, palmitic acid, and behenic acid respectively and from the observed depressions of the melting points, taking into consideration also the iodine value of the acids from the hydrogenated oil, the composition of the mixed fatty acids was calculated. According to this method the fatty acids of cottonseed oil contain 25·9% palmitic acid and 72·8% unsaturated C_{18} acids; and those of menhaden oil contain: palmitic acid, 22·7; other solid saturated acids, 11·8; unsaturated C_{16} acids, 0·0; unsaturated C_{18} acids, 26·7; unsaturated C_{22} acids, 20·2; other unsaturated acids, 18·6%.—A. S.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Turpentine; Study of authentic samples of gum ——. A. W. Schorger. J. Ind. Eng. Chem., 1914, 6, 541—548.

From the examination of 67 samples collected at different times and under different conditions, the following values for the physical characters of normal, freshly distilled gum turpentine are given:—sp. gr. at 15° C., 0·8659—0·8722 (average 0·8685); refractive index at 15° C., 1·4714—1·4746 (1·4730); initial boiling point, 154°—157·6° (156° C.). The first distillation fraction, amounting to 2·5%, has a sp. gr. not lower than 0·8630 (average about 0·8640) and an index of refraction not lower than 1·4675 (average 1·4690). A first fraction of 5% should have sp. gr. not lower than 0·8640 (average 0·8650) and index of refraction not lower than 1·4690 (average 1·4700). At least 86%, usually 91—93%, should distil up to 165° C., and at least 93%, usually 97%, up to 170° C. The residue (5%) should have sp. gr. not lower than 0·8875 (average 0·9140). Figures are also given showing the influence of variations in the time and method of collection on the characters of the turpentine and the effect of exposure. Storage with reasonable care for 1 year has little or no effect on the physical properties of turpentine. —A. S.

Varnishes; Examination of [detection of cobalt and manganese in] ——. G. Malatesta and E. di Nola. Boll. Chim. Farm., 1914, **53**, 6—7. Chem. Zentr., 1914, **2**, 173.

Cobalt salts are now used as siccatives, and their presence in varnishes may be detected by testing a solution of the varnish in an organic solvent with the 1.2-diaminoanthraquinone-3-sulphonic acid reagent (see this J., 1914, 335), which gives an immediate deep green coloration, soon separating into a deep blue lower and a yellow upper layer, if cobalt be present. If the varnish, or a solution of it in an organic solvent, be shaken with an acetic acid solution of nitroso-β-naphthol, a red coloration is produced if cobalt be present, and a red precipitate of the cobalt salt separates. Cobalt may also be detected by the characteristic blue coloration produced with concentrated ammonium thiocyanate solution. Manganese may be detected by adding hydrogen peroxide to a solution of the varnish in ether, a brown precipitate of manganese oxide being produced.—A. S.

Patents.

Paint; Process for the production of ——. M. Wasse mann, Kalk, Germany. Eng. Pat. 14,220, June 1 1913. Under Int. Conv., Dec. 21, 1912.

Train or fish oil is sulphonated with strong sulphuric aci below 40° C., and the product "salted out," washe heated with copper suboxide, and treated with litharg to obtain a paint for metal, wood, and building surface —C. A. M.

Ink; [Luminous] ——. E. F. Krapp, Assignor to J. Flannery, Pittsburgh, Pa. U.S. Pat. 1,097,981, May 2 1914; date of appl., Aug. 15, 1912.

Colloidal radioactive material and metallic sulphide a incorporated with the ink, which, for printing, may al contain burnt oil, rosin and soap.—C. A. M.

[Printing] Ink; Manufacture of ——. H. Sureti London. Eng. Pat. 14,245, June 19, 1913.

Peat is heated with an alkali silicate or equivalent alk solution, and the residue incorporated with pigment, c varnish, etc., to obtain a printing ink.—C. A. M.

Pigment colours; Process for preparing ——. Farbwer vorm. Meister, Lucius, und Brüning. Ger. Pat. 273,3 Oct. 23, 1912.

The diazo derivative of an aromatic nitroamine or substitution product thereof is combined with a sulphazo and the product is converted into a lake by aid of bari sulphate, alumina, kaolin, etc. The resulting pigments fast to water and light and insoluble in oil.—T. F. B.

Kiln for removing the chemically-combined water in pigme especially zinc sulphide pigments, and similar materia Tubular rotary ——. J. Küppers. Ger. Pat. 274,4 March 27, 1913.

The kiln consists of a cylindrical firebrick muffle provi inside with longitudinal ribs and mounted within spaced apart from an outer firebrick casing, the wh being mounted so that it can be rotated and inclined any desired angle. At one end of the kiln are a fe hopper for the material and outlets for the water-vap and heating gases, and at the other end are a discharg device and a firing device for gaseous, liquid, or powde fuel provided with burner nozzles projecting into annular space between the muffle and the outer cas —A.

[Rosin] Extractor. J. H. Castona, Gulfport, Miss. Pat. 1,098,312, May 26, 1914; date of appl., Oct. 9, 1

An outer casing encloses a perforated extraction chan above a rosin-collecting chamber. An axial perfora steam pipe rises from a steam space enclosing a hea coil for solvent, which is delivered to a perforated above the extraction chamber.—O. E. M.

Turpentine and resinous substances from wood ; Apparatus for extracting ——. F. W. Waterman, Baltimore, Md. U.S. Pat. 1,099,779, June 9, 1914 ; date of appl., Oct. 6, 1910.

THE wood is distilled under pressure in a retort connected at the bottom with the top of a digester, where the residue from the distillation of the turpentine is heated under pressure with a circulating liquid, to extract the resinous substances.—C. A. M.

Condensation products from phenols and formaldehyde ; Process for the manufacture of —— and of new materials formed therewith. H. Stockhausen, Crefeld, and R. Gruhl, Charlottenburg, Germany. Eng. Pat. 14,481, June 23, 1913.

A FLUID condensation product of formaldehyde and a phenol is kneaded at 30° to 50° C. with salts of trivalent netals (*e.g.*, 50% $FeCl_3$ calculated on the phenol), and vith or without sulphur, rubber, filling materials, etc., and, fter separation of water, the mass is heated to obtain an afusible insoluble product. In preparing an initial ondensation product the reaction may be interrupted by udden cooling, at the point of incipient turbidity. laterials, such as wood, paper, cork or fabrics may be npregnated with the condensation product prior to its ransformation into an insoluble form and then compressed nd heated.—C. A. M.

esinous condensation product and process of making the same. K. B. Howell, Schenectady, N.Y., Assignor to General Electric Co. U.S. Pat. 1,098,728, June 2, 1914 ; date of appl., July 25, 1913.

MIXTURE of castor oil (320 parts) and an ester of a olyhydric alcohol and a polybasic acid containing free ydroxy groups (*e.g.* that obtained by the interaction of bout 184 parts of glycerin and 296 parts of phthalic nhydride) is heated to obtain a flexible resin soluble a mixture of alcohol and benzene and fusible without ecomposition.—C. A. M.

XIV.—INDIA-RUBBER ; GUTTA-PERCHA.

ttapercha resin ; Vulcanisation of ——. R. Ditmar. Gummi-Zeit., 1914, 28, 1626.

IXINGS of gutta-percha, resin, and sulphur, containing spectively 20·83, 25·74, 28·50, and 31·90% of the tter, were vulcanised for 4 hours at 7 atmospheres eam pressure, and filings of the ebonites obtained re extracted for 8 hours with acetone. A determina- n of free sulphur in the acetone extract was made each case, and the soluble resins estimated by fference. The results showed that a portion of the ins had on vulcanisation been rendered insoluble in etone. The figures obtained for this vulcanised resin re respectively 1·81, 4·39, 3·97, and 2·27%, calculated on gutta-percha, in the four samples. The explanation ered of the occurrence of a maximum value is that the lcanised resin dissolves in excess of sulphur, and that solution formed is soluble in acetone. It is suggested t the behaviour of the resins on vulcanisation may nstitute a means of differentiating between different ts of gutta-percha, and it is pointed out that the resin- ntent of the gutta-percha employed cannot be deduced m the values for acetone-extract of a vulcanised nple.—E. W. L.

Keratin-like substances ; Separation of particles of flesh and skin from —— in animal products. R. Berth, offene Handelsges. Ger. Pat. 273,769, Nov. 21, 1913.

PARTICLES of flesh and skin are removed from keratin-like substances, *e.g.* animal bristles, by treatment with dilute acids, especially hydrochloric acid, or digestive enzymes, or mixtures of the same.—A. S.

XVI.—SOILS ; FERTILISERS.

Nitrates ; Excessive quantities of —— in certain Colorado soils. W. P. Headden. J. Ind. Eng. Chem., 1914, 6, 586—590.

A BRIEF account of the investigations on the occurrence and origin of excessive quantities of nitrates in certain Colorado soils (Colorado Expt. Stat., Bulls. 155, 160, 178, 179, 183, 184, 186, and 193). The quantities of nitrates vary from a few tenths to over 6% of the air-dried soil, and the affected areas, distributed throughout the cultivated sections of the State, vary from a few square feet to many acres, and in many cases show a tendency to spread very rapidly. The affected areas have a characteristic brown colour ; and the effects produced on vegetation can be reproduced by excessive manuring with sodium nitrate (see this J., 1913, 1122) but not with sodium chloride. Azotobacter, which produces a pigment of colour similar to that of the affected areas, occurs very abundantly and the soils exhibit high nitrogen-fixing, ammonifying, and nitrifying powers. The algal flora of the soils is abundant and sufficient to furnish the energy necessary for the growth of azotobacter. The position and character of the affected areas and the composition of the natural water of the regions appear to exclude the possibility of the accumulation of nitrates being due to concentration of pre-existing ready-formed nitrates by the agency of water, and the view is put forward that the phenomena are due primarily to fixation of atmospheric nitrogen by azotobacter. (Compare Stewart and Greaves, Agric. Expt. Stat., Utah, Bull. 114.)—A. S.

Soils ; Distribution of certain constituents in the separates of loam ——. L. A. Steinkoenig. J. Ind. Eng. Chem., 1914, 6, 576—577.

TEN different soils (3 from N. Carolina, 2 from Pennsylvania, and 1 each from New York State, S. Carolina, Virginia, New Hampshire, and Wisconsin) were each separated by sedimentation and centrifuging into fine sand (particles 0·1—0·05 mm. diam.), coarse silt (0·05—0·025 mm.), and fine silt and clay (up to 0·025 mm.), and the different fractions analysed. The distribution of the various constituents in the fractions is shown in the following table, the figures being percentages on the material dried at 110° C.

Carbon in soils and soil extracts; Determination of ——. J. W. Ames and E. W. Gaither. J. Ind. Eng. Chem. 1914, **6**, 561—564.

Using 1—3 grms. of soil ground to pass a 60-mesh sieve, the whole of the organic carbon present therein can be oxidised, and all carbon dioxide chemically or mechanically combined can be liberated, by boiling for 30 mins. with a mixture of 3·3 grms. of chromic acid dissolved in 10 c.c. of water and 50 c.c. of sulphuric acid of sp. gr. 1·84. If the mixture be diluted with 50 c.c. of water the results obtained are too low, as also are those obtained by the alkaline permanganate method. It is recommended that the evolved carbon dioxide be absorbed in 4% sodium hydroxide solution and the sodium carbonate determined by double titration, with phenolphthalein and methyl orange as indicators. An apparatus for carrying out the process, including a modified form of the Ames absorption tower (J. Agric. Sci., 1908, **1**, [3], 322), is described. The method can also be used for determining carbon in 1% hydrochloric acid extracts and 4% ammonia humus solutions obtained from soils, without first concentrating these below 50 c.c.—A. S.

Guano; Penguin —— from the Falkland Islands. Bull. Imp. Inst., 1914, **12**, 208—210.

Five samples of guano contained from 64 to 80% of moisture; one sample lost 70% on exposure to air for 6 days. The composition of the samples calculated to a normal moisture content of 20% was: N 2·71—5·05; K_2O 0·46—0·98; P_2O_5 3·41—12·45%. Compared with good Peruvian guano the samples were deficient in fertilising constituents.—R. G. P.

Nitrogen in kelp; Availability of ——. J. A. Cullen. J. Ind. Eng. Chem., 1914, **6**, 581—582.

Dry kelp contains, on the average, 2% N. As determined by the official (U.S.A.) alkaline permanganate method, the available nitrogen amounted to from 13·4 to 44·8% of the total. Under these conditions, however, the whole of the organic matter was not oxidised, and by increasing the quantity of permanganate, practically the whole of the nitrogen could be converted into an available form.—A. S.

"Neutral" ammonium citrate; Preparation of ——. E. D. Eastman and J. H. Hildebrand. J. Ind. Eng. Chem., 1914, **6**, 577—580.

Determinations with the aid of the hydrogen electrode (compare Hildebrand, J. Amer. Chem. Soc., 1913, **35**, 848, 1538) showed that normal ammonium citrate solution is slightly alkaline, the hydrogen ion concentration being $10^{-7\cdot4}$. It can be prepared by dissolving 370 grms. of citric acid in 1500 c.c. of water, nearly neutralising with concentrated ammonia, cooling to 20° C., and then adding ammonia gradually until a 10 c.c. portion with 2 drops of rosolic acid solution (0·25 grm. in 50 c.c. of alcohol and 50 c.c. of water) gives the same colour as 10 c.c. of a standardised phosphate solution gives with the same quantity of indicator. To prepare the phosphate solution, 25 c.c. of 0·1 molar solution of disodium phosphate (made neutral to phenolphthalein by hydrochloric acid or sodium hydroxide) is titrated with $N/10$ hydrochloric acid in presence of methyl orange. To a fresh 25 c.c. portion of the phosphate solution one-sixth of the volume of acid used in the previous titration is added, and 10 c.c. of the resulting solution are used to prepare the colour standard. The neutralised citrate solution is diluted till it has the sp. gr 1·09 at 20° C. It is suggested that in the determination of available phosphate in a fertiliser, it might be preferable to use a citrate solution containing an excess of acid or of ammonia rather than the neutral solution, since then the hydrogen ion concentration would be far less affected by slight variations in the relative quantities of citric acid and ammonia present It might also be desirable to maintain a constant hydrogen ion concentration during the determination by adding either ammonia or citric acid so as to produce a definite colour in presence of a suitable indicator.—A. S.

Calcium cyanamide; Process of rendering —— non-dusting. F. S. Washburn, Nashville, Tenn. U.S. Pat 1,098,651, June 2, 1914; date of appl., Oct. 3, 1912.

Commercial calcium cyanamide is mixed with wate and a binding medium, formed into briquettes unde pressure, the briquettes crushed, and sifted so as to yiel granules passing a screen of 8 meshes and retained by one of 15 meshes per sq. in. The coarser granules ar further crushed and the finer particles are again briquetted —A. S.

Fertiliser and process of making the same. F. S. Washburn Nashville, Tenn. U.S. Pat. 1,100,638, June 16, 1914 date of appl., Nov. 5, 1913.

A crystalline, non-deliquescent fertiliser, stable und normal conditions, and composed of a double sulphat and phosphate of ammonium, is obtained by treatin phosphate rock with excess of sulphuric acid, extractin the soluble constituents from the mass, and treatin the solution with excess of ammonia.—A. S.

Treatment of sewage and like organic refuse. Eng. Pa 5921. *See* XIXb.

XVII.—SUGARS; STARCHES; GUMS.

After products [Sugar]; Working up ——. O. Moien and F. Petters. Z. Zuckerind. Böhm., 1914, 3 503—517.

In dealing with low product massecuites the m important requirement is to maintain a correct co centration with falling temperature so that, on centrifugi at 40°—50° C., the molasses is only just saturated or ve slightly supersaturated. When the mother-liquor in t molasses is strongly oversaturated, crystallisation impeded and hence the molasses shows too high a quotic of purity. It thus becomes necessary to determine wh concentration the molasses must have in order to poss the slight requisite supersaturation. Samples of molas obtained from five different massecuites by centrifugi two at 45°, two at 44° and one at 43° C., were mi with pure sugar crystals free from dust and kept at t temperatures mentioned for 240 hours, the vessels be turned over at intervals, and the resulting mass cen fuged. In the analysis of the original and the trea molasses, the apparent solids determined by the pycnome on the undiluted sample and the sugar determined the Clerget method were used to calculate the pu of the molasses. The maximum reduction in the pu after treatment was 1·47 and the minimum 0·73, but connection was found between the crystallisation ef and the supersaturation coefficients. The treated mola in one case contained 14·47% of water and 49·75 of su one part of water thus holding 3·44 parts of sugar solution. Since the corresponding figure for a solutio pure sugar at 45° C. is 2·48, the coefficient of supersatu tion is 3·44 ÷ 2·48 = 1·39. The other results obtained w for 45° C., 1·32, for 44° C., 1·37 and 1·39 and for 43° 1·28.—L. J. de W.

Sucrose; Melting point of ——. B. Burne. Chem. N 1914, **110**, 47.

The melting point of sucrose is stated to be 185°—186° not 160° C. as given in the text-books.—A. S.

Starch and its transformations; Some notes on the chem of ——. W. A. Davis. J. Soc. Dyers and Col., 1 **30**, 249—255.

O'Sullivan's method of starch determination gave re 10—15% too low in cases where proteins, tannins, etc., to be removed, owing to dextrin being precipitated by basic lead acetate. Other methods also proved unsati tory, so a method was devised using taka-diastase this J., 1914, 657). The reaction depends on the maltase in the ferment, which causes the decomposition of the maltose first formed into dextrose. The first part of the reaction is rapid, dextrin being usually absent after 6 hours. This is due to the removal of the maltose as it is formed, and contrasts with the action of ordinary diastase which slows down when 80% of the starch has been converted. No such halt takes place in the case of taka-diastase, but there is a halt in the final reaction—the conversion of maltose into dextrose. The author explains the conversion of maltose by maltase by the following reactions, assuming maltose to be glucose-α-glucoside: (1) β-glucose-α-glucoside→α-glucose-α-glucoside, (2) α-glucose-α-glucoside→2 mols. α-glucose, (3) α-glucose→equilibrium mixture of α- and β-glucose showing $[\alpha]_D = 52\cdot70$. The disturbing influence of stages (1) and (3) explain why the reaction is not logarithmic. When these influences are not present the time law is that of a unimolecular reaction, as is the case in the conversion by acid.—J. B.

issolving sugar or other substances ; Apparatus for ——. Maschinenfabrik Grevenbroich (vorm. Langen und Hundhausen), Grevenbroich, Germany. Eng. Pat. 26,357, Nov. 17, 1913. Under Int. Conv., Dec. 27, 1912.

E Ger. Pat. 266,335 of 1912 ; this J., 1914, 14.—T. F. B.

XVIII.—FERMENTATION INDUSTRIES.

Malt analysis ; New [German] standards for ——. G. Bode and A. Wlokka. Allgem. Zeits. Bierbrau. u. Malzfab., 1914, **42**, 291—295.

THESE standards have been adopted by the Verein Deutscher Chemiker, to take effect from Sept. 1, 1914. Sampling to be done either by a borer (Barth-Eckhardt's recommended) or by an automatic sampler (Grafe's or Wlokka's). Malt in bulk to be shovelled over and samples taken at different depths ; in the case of sacks, 10% of the sacks to be sampled. Samples to be protected against changes in moisture-content ; the portion sent for analysis to be at least 400 grms. Large foreign bodies may be rejected ; small foreign corns and dust to be retained in the sample. The standard sifting apparatus for grist and meal, made by Seck to the specification of the Pfungstadt brewery, is adopted and details for its operation are prescribed. The mills are standardised with the help of this apparatus and a normal malt containing 4% of moisture and showing between 0·6 and 1% difference between the extracts from grist and meal. The grist mill is to be set so that the three finest fractions on the standard screens with this malt amount to 40 ± 1%. The fine mill must yield 90 ± 1% in the three finest fractions. For the determination of moisture in grist, these fractions must amount to 60%. For trade analyses the moisture is to be determined in fine meal :—10 grms. of malt are ground and duplicate portions of 5 grms. dried for 3 hours in a standard oven above 100° C. For controlling the standard oven, samples of grist or meal from four malts of very different constitution, contained in drying bottles 40 mm. in diam. and 25—30 mm. in height, are heated in the oven for 3 hours. The duplicate results must agree within 0·1%. Further heating for one hour must not cause a loss exceeding 0·1% ; if the difference is greater, the tests must be repeated with the oven temperature 1° higher, but in no case exceeding 108° C. Drying ovens by Scholvien, Ulsch and V.L.B. have been approved ; other systems are not permitted until approved. For trade analyses the extract is only determined in the fine meal, samples to be ground separately from those for moisture determination. Mashing beakers and stirrers to be of the same metal, not nickel-plated. Propeller to revolve at an uniform speed of 80—100 revs. per min., with a clearance at sides and bottom of the beaker, the latter being 1—2 mm. :—50 grms. of the entire-ground meal are mixed with 200 c.c. of water at 45° C., placed in the bath at 45° C., stirred for 30 mins., then heated to 70° C. at the rate of 1° C. per min. ; on reaching 70° C., 100 c.c. of water at 70° C. are added and the mash is stirred for one hour, cooled to the ordinary temperature in 10—15 mins. and made up to 450 grms. The whole mash is poured on to a C. S. and S. No. 560 folded filter, 32 cm. diam., the first 100 c.c. of wort being returned. The dimensions of the standard pyknometer of 50 c.c. capacity are specified. The density of the wort is determined at 17·5° C. ; the results of duplicate mashings must not differ by more than 2 in the fourth decimal place ; values are calculated by Balling's tables. The time of saccharification is determined in a separate mash, starting 10 mins. after reaching 70° C., by spotting on a plaster of Paris plate with $N/50$ iodine solution, the test being repeated every 5 mins. If saccharification is not complete after 1 hour, the mash is to be repeated at 75° C. The colour of the wort is to be estimated by Brand's colour solution, based on $N/10$ iodine, which must be obtained fresh every year from the Münich station. Mechanical analysis and the determination of extract from grist are only to be performed by special request.—J. F. B.

Yeast ; Oxidation and reduction processes effected by dead —— *at the expense of water.* W. Palladin and E. Lowtschinowskaja. Biochem. Zeits., 1914, **65**, 129—139.

IT has been suggested that the first stages of anaerobic respiration and alcoholic fermentation consist of a series of oxidation and reduction reactions at the expense of water. During the respiration, the hydrogen set free from the water is taken up by hydrogen-acceptors (this

J., 1914, 328) and finally converted into water again, whilst in alcoholic fermentation (and in absence of oxygen during anaerobic respiration), the hydrogen ultimately converts the primary decomposition products of the sugar into alcohol. Gluconic acid appears to be one of the primary products of fermentation of glucose and it is found that the decomposition of potassium gluconate by dead yeast ("Hefanol" or dried yeast) is greatly accelerated by addition of methylene blue (a hydrogen-acceptor), a much larger quantity of carbon dioxide being liberated. Potassium lactate is similarly affected. The decomposition of these compounds in presence of a hydrogen-acceptor appears to be the first successful attempt to transform fermentation into respiration artificially.—L. E.

Invertase ; Inversion of sucrose by ——. VIII. Improved method for preparing strong invertase solutions from top or bottom yeast. C. S. Hudson. J. Amer. Chem. Soc., 1914, **36**, 1566—1571. (See this J., 1910, 443.)

A MUCH more active preparation of yeast invertase is obtained if the yeast is autolysed in presence of toluene than if chloroform is used. Twelve kilos. of pressed bottom-fermentation beer yeast are kneaded with 12 litres of tap water and 750 c.c. of toluene, left for 4—5 days and filtered. The filtrate is clarified with normal lead acetate, freed from excess of lead with hydrogen sulphide, and dialysed in a collodion sac. The dialysed solution may be preserved with toluene at the ordinary temperature for a month without any loss of activity ; and it hydrolyses sucrose in the course of a night under usual analytical conditions. The invertase obtained from top yeast is less active.—L. E.

Invertase ; Inversion of sucrose by ——. IX. Is the reaction reversible? C. S. Hudson and H. S. Paine. J. Amer. Chem. Soc., 1914, **36**, 1571—1580.

CONTRARY to the statements of other workers (cp. Kohl, this J., 1908, 824), yeast invertase hydrolyses sucrose completely, the reaction being non-reversible. Further, Osaka's view that the hydrolysis of sucrose by hydrochloric acid may be reversible (this J., 1908, 1125) is not confirmed.—L. E.

Beer turbidity due to calcium fluoride. H. Will. Z. ges. Brauw., 1914, **37**, 357—358.

THE turbidity was traced to the use of fluoride as antiseptic (in quantity equivalent to 0·001% HF) ; the beer sediment consisted chiefly of calcium fluoride.—L. E.

Determination of malt extract. Dreaper. *See* VI.

Determination of mannitol. Smit. *See* XXIII.

PATENTS.

Brewing ; Process of ——. H. Heuser, Chattanooga, Tenn. U.S. Pat. 1,099,746, June 9, 1914 ; date of appl., May 23, 1912.

THE wort is fermented and transferred to the chip cask, being heated, during the transfer to about 40° F. (4·4° C.). It is treated with "kraeusen" in the chip cask and left to undergo secondary fermentation.—L. E.

Mashes or worts ; Process for transferring atmospheric oxygen, bacteria, aromatic substances, etc., to ——. O. Schulze. Ger. Pat. 274,777, Aug. 28, 1912.

A MIXTURE of hot water spray and air is led over the wort or mash in a closed vessel provided with an outlet pipe and condenser, whereby the steam is condensed on the surface of the wort or mash, and the air thus brought into intimate contact with the latter. Bacteria, aromatic substances, etc., may be mixed with the air.
—A. S.

Yeast and the like ; Dryers for ——. J. H. A. Wiesener, Hamburg, Germany. Eng. Pat. 25,392, Nov. 6, 1913.

A ROTATING horizontal drum is mounted over a trough, the interior of the drum and trough being heated by steam-pipes. Yeast is supplied from a hopper to the trough and, as it liquefies in the latter, a layer of definite thickness is carried round on the surface of the drum ; the dry film is removed by means of a scraper before the drum has made a complete revolution.—W. P. S.

Method of and apparatus for neutralising acid [sulphite lyes. U.S. Pats. 1,098,561 and 1,098,562. *See* V.

XIXa.—FOODS.

Caffeine in coffee ; Determination of ——. G. Fendler an W. Stüber. Z. Unters. Nahr. Genussm., 1914, 28 9—20.

THE methods of Lendrich and Nottbohm (this J., 190 379) and Katz (this J., 1902, 1300) though reliable an accurate, are tedious, and that of Keller (this J., 1897, 56 is untrustworthy. The following modified method i proposed, and results of determinations are given to sho that accurate results may be obtained. Ten grms. the finely powdered coffee (passed through a sieve of 1 mn mesh) are shaken for 30 mins. with 10 grms. of 10° ammonia and 200 grms. of chloroform ; the whole of th mixture is then poured on a large filter and 150 grms. the filtrate are transferred to a wide-necked flask an evaporated to dryness on a water-bath. The residue heated for 10 mins. with 80 c.c. of water, cooled, an 20 c.c. of 1% potassium permanganate are added ; aft 30 mins. the mixture is treated with a slight excess hydrogen peroxide solution (100 c.c. of 3% hydrog peroxide *plus* 1 c.c. of glacial acetic acid), and then heat on a water-bath, further quantities of hydrogen peroxi being added if the pink coloration has not disappeare After cooling, the mixture is filtered, the insoluble porti and the filter washed with cold water, and the filtrat measuring about 200 c.c., extracted four times wi chloroform, using 50, 25, 25, and 25 c.c. of the latt The chloroform extracts are evaporated in a weigh flask, the residue is dried for 30 mins. at 100° C., a weighed.—W. P. S.

Cocoa ; Examination of stabilised ——. L. Reutt Schweiz. Apoth.-Zeit., 1914, **52**, 308—312, 322—3 335—339. Chem. Zentr., 1914, **2**, 169—170.

THE fermentation process to which cacao beans subjected for the purpose of facilitating the separati of the nibs from the pulp produces considerable chan in the composition of the nibs, and recently it has be replaced by treatment with a 1% solution of sodi carbonate for 10 mins. at 45° C., whereby the beans "stabilised" and sterilised. Cocoa prepared in t way is perfectly stable, and contains no pre-formed sug Theobromine is not present in the free state, but is form together with sugar and tannin by hydrolysis. (See a this J., 1913, 709.)—A. S.

PATENTS.

Inorganic enzymes and their application for baking purpo L. Weil, Strassburg, Germany. Eng. Pat. 12,6 May 30, 1913. Under Int. Conv., June 3, 1912.

A PREPARATION consisting of colloidal manganese, calcium glycerophosphate, 5, magnesium lactophosph 0·8, colloidal silicic acid, 0·03, and potassium hydrox 0·02 grm., in 1 litre of 65% sugar solution is obtained dissolving these constituents separately in a small quan of water, adding sugar syrup, mixing the solutions, diluting the mixture with the concentrated sugar solut One kilo. of this preparation is added to the water in making dough from 100 kilos. of flour, in order to incr the enzymic activity of the latter.—W. P. S.

Extracts rich in enzymes and nitrogenous matters for use in baking, for medicinal and other purposes; Process of manufacturing highly active ——. M. Hamburg, Bishop's Stortford, Herts. Eng. Pat. 13,928, June 16, 1913.

Extracts rich in enzymes and nitrogenous substances are obtained by subjecting malted cereals mixed with wheat germ, wheat bran, and malt culms to successive mashing processes at temperatures ranging from 130° F. (55° C.) to 150° F. (65° C.), mixing the liquors and concentrating the same under reduced pressure. Modifications of the process are described.—W. P. S.

Flour and the like; Treatment of ——. B. I. Levin, Manchester. Eng. Pat. 12,917, June 4, 1913.

Flour admixed with solid "improvers" is treated with a quantity of water, in the form of a fine spray, sufficient to enable the full effects of the "improvers" to be obtained.—W. P. S.

Flour treatment. B. I. Levin, Manchester. Eng. Pat. 13,696, June 13, 1913.

Flour is sprayed with liquids obtained by the electrolysis f solutions of such substances as phosphoric acid, acid hosphates, chlorates, or ammonium salts, etc.—W. P. S.

Flour; Apparatus for treating ——. J. A. Wesener, Chicago, Ill. U.S. Pat. 1,099,225, June 9, 1914; date of appl., March 6, 1913.

s an apparatus for ageing and bleaching flour, means are rovided for subjecting the latter to a current of air harged with a suitable gas, the latter being stored in a iquid form in containers.—W. P. S.

hortening-composition [for flour]; Dry ——. A. W. Estabrook and H. E. Weaver, Kansas City, Assignors to The Larabee Flour Mills Co., Hutchinson, Kans. U.S. Pat. 1,101,015, June 23, 1914; date of appl. June 14, 1913.

lour containing an added powdered stearate is mixed ith an acid salt; the latter decomposes the stearate nd the liberated fatty acid acts as a "shortening" agent. —W. P. S.

ood for cattle and other animals; Manufacture of ——. J. J. Eastick and J. J. A. de Whalley, London. Eng. Pat. 14,607, June 24, 1913.

eat moss, containing about 30% of moisture, is treated an autoclave with 3·5% of its weight of gaseous sulphur ioxide, and then heated for about 30 mins. by the introuction of steam under a pressure of 100 lb. per sq. in. —W. P. S.

ood from whole grain; Process for the manufacture of an ensily digestible ——. C. Mauterer, Karlsruhe i.B., Germany. Eng. Pat. 18,837, Aug. 19, 1913.

ereal grains from which the husk has been removed are eeped in water, then heated to about 100° C., dried, and ated with a glazing composition such as sugar or chocote, etc.; sufficient of the latter may be employed to form e grains into a mass. The glazing composition may also ntain ground nuts, fruits, diastase, iron saccharate, emoglobin, etc.—W. P. S.

verages and the like; Manufacturing a powdered extract for use in the preparation of ——. J. L. Kellogg, Battle Creek, Mich. U.S. Pat. 1,097,720, May 26, 1914; date of appl., Jan. 28, 1914.

arley malt, 1, and a suitable starchy material, 2 parts, e mixed with water to form a paste which is heated to 170° F. (77° C.) until the starch is converted; the mixture is then further heated for 5 hours under a pressure of about 40 lb. per sq. in., and mixed with bran, malt germs, and roasted ground rye. This mixture is dried, roasted, extracted with water, and the extract is evaporated under reduced pressure and ground to a powder.—W. P. S.

Beverage extract. W. H. Post, Assignor to Postum Cereal Co., Battle Creek, Mich. U.S. Pat. 1,098,683, June 2, 1914; date of appl., Feb. 7, 1913.

The extractive matters of sweet potatoes are mixed with molasses and the mixture is roasted to caramelise the sugar.—W. P. S.

Fermented-milk product and process of making the same. A. H. Thoumaian, Baltimore, Md. U.S. Pat. 1,101,044, June 23, 1914; date of appl., May 17, 1913.

A mixture of egg albumin, milk, and cream is submitted to the action of a culture of lactic acid bacillus and *Bulgaricus bacillus*.—W. P. S.

Food substances; Process of preserving ——. W. H. Allen, Detroit, Mich. U.S. Pat. 1,098,006, May 26, 1914; date of appl., Aug. 11, 1913.

A sufficient quantity of hydrochloric acid is added to a vegetable pulp (tomato pulp) to render the latter sterile and the acid is then neutralised by the addition of sodium carbonate.—W. P. S.

Eggs; Method of desiccating ——. T. Hara, San Francisco, Cal. U.S. Pat. 1,100,973, June 23, 1914; date of appl., June 23, 1913.

Yolks and whites of eggs are beaten up separately, then mixed and dried in thin layers on metallic plates heated to about 110° F. (43° C.), the drying operation being carried out in a dark room the air in which is dried and heated to about 105° F. (40° C.).—W. P. S.

XIXb.—WATER PURIFICATION; SANITATION.

Hardness of waters; Determination of —— *by the methods of Wartha-Pfeifer and Blacher. II. Blacher's method.* J. Zink and F. Hollandt. Z. angew. Chem., 1914, **27**, 437—440. (See this J., 1914, 564.)

In Blacher's method the water is neutralised, the carbonic acid blown off with air, and the water then titrated with potassium palmitate solution, in presence of dimethylaminoazobenzene, with shaking, until a distinct red colour is produced. The authors find that it is better to use methylorange as indicator and to boil off the carbonic acid, but that for the total hardness, both these precautions are unnecessary and the water may be titrated directly in presence of phenolphthalein. They recommend that the process be carried out on 100 c.c. of the water, which, after addition of a drop of dimethylaminoazobenzene, is titrated with $N/10$ hydrochloric acid until a reddish violet colour is formed; the liquid is then boiled for 10 mins., cooled, and after addition of phenolphthalein, is titrated with $N/10$ caustic soda until faintly red, and then with $N/10$ acid until pure yellow again. The titration with potassium palmitate is next carried out, with shaking, until a permanent red colour is produced. The palmitate is standardised against lime water or a salt of any of the alkaline-earth metals. The method gave in a series of tests 87·5% of results with a less difference than 0·6 degrees German from a quantitative analysis. Humus does not affect the results, but iron and manganese raise them owing to formation of metallic soaps; on the other hand, iron salts, being precipitated at the neutral point,

may carry down calcium and magnesium salts and in this way lower the results. Instead of the palmitate a myristin soap solution is suitable. The method may be used for the determination of the sulphates in waters by precipitating with barium chloride after boiling and before titrating with the palmitate solution, the removal of the barium sulphate being unnecessary. It is concluded that Blacher's method is superior to the usual titration method in simplicity of execution and accuracy of results.
—J. H. J.

Protein-ammonia [e.g., in drinking water]; Determination of ——. L. W. Winkler. Z. angew. Chem., 1914, 27, 440.

The method, which is specially designed for drinking waters, consists in adding potassium persulphate to the acid mixture, heating, and estimating the ammonia without distillation. 100 c.c. of the water are acidified with one drop of concentrated sulphuric acid and 0·05 grm. of pure powdered potassium persulphate added. The flask is heated in the steam bath for ½ hour, then cooled, and 5 c.c. of a mixture of equal vols. of Nessler's reagent and a solution of Rochelle salt added. A second test is prepared in the same manner, without heating, with the final addition of standard ammonium chloride solution to equal the colour of the first test. It was found that all pure natural waters contain no protein-ammonia, the limit which a drinking water should not exceed being 0·1 mgrm. per litre.—J. H. J.

Hypochlorite of lime treatment of a municipal water supply and a study of certain resistant bacteria. S. J. Thomas. J. Ind. Eng. Chem., 1914, 6, 548—552.

Experiments carried out in connection with the treatment of the water supply of Bethlehem, Pa., U.S.A., by means of bleaching powder showed that the non-pathogenic organisms, *Bac. subtilis, Micrococci agilis, Bact. aerophilum,* and *Bac. subcuticularis* are capable of resisting the action of bleaching powder at a concentration of 2 parts per million.—A. S.

Chlorine [in water]; Effect of ferric salts and nitrites on the ortho-tolidine and starch-iodide tests for free ——. J. W. Ellms and S. J. Hauser. J. Ind. Eng. Chem., 1914, 6, 553—554.

Under suitable conditions colour changes are produced in solutions of *o*-tolidine not only by chlorine (this J., 1913, 1125) but by all oxidising agents. Ferric salts and nitrites are the only oxidising agents likely to be met with in natural waters and these must be present in quantity equivalent to 0·9—1 part Fe or nitrite-N per million in order to produce a colour. Moreover they can readily be detected by qualitative tests. The starch-iodide method is affected by ferric salts and nitrites in a similar manner.—A. S.

Patents.

Water; Apparatus for the electrical purification of ——. H. B. Hartmann, Assignor to G. A. Dunning, Philadelphia, Pa. U.S. Pat. 1,101,278, June 23, 1914; date of appl., Aug. 11, 1911.

The discharge pipe from an electrode chamber is provided with a gas pocket and the flow of water from this pocket controls the supply of current to the electrodes; an electro-magnetic valve regulates the flow of water through the electrode chamber towards the gas pocket, the valve being held open while the current is supplied to the electrodes.—W. P. S.

Sewage and like organic refuse; Process for the treatment of ——. J. C. Butterfield, London. Eng. Pat. 5921, Mar. 10, 1913.

Sewage, etc., is heated with petroleum (0·5 to 4·0%) in a closed retort at a low temperature (500°—800° F., 260°—427° C.), the fats, etc., are separated from the distillate, and the residue redistilled at 1000° to 1200° F. (538°—649° C.). The final residue, containing lime, animal charcoal and phosphoric acid, is used for precipitating more sewage, until eventually a residue rich in phosphoric acid and suitable for use as a fertiliser is obtained.—C. A. M.

Town refuse; Apparatus for burning ——. I. R. Glaskin, London. Eng. Pat. 17,420, July 29, 1913.

A preliminary combustion of the refuse is effected in a cylindrical chamber forming a continuation of the inlet shoot at the top of a vertical cupola furnace, and the combustion is completed in the chamber below by the aid of tangential blasts of hot air under pressure. The slag is cooled by water-jackets, and the heat from the products of combustion is utilised.—C. A. M.

Garbage; Method for disposing of ——. A. H. Woollacott and L. H. Saxton, Los Angeles, Cal. U.S. Pat. 1,099,330, June 9, 1914; date of appl., Feb. 10, 1913.

The garbage is ground to form a slurry which is stored and stirred in closed tanks and subsequently lifted and dropped through an incinerating flame.—W. P. S.

Garbage; Art of utilising ——. J. M. W. Kitchen, East Orange, N.J. U.S. Pat. 1,101,129, June 23, 1914. date of appl., Oct. 11, 1912.

The garbage is finely divided, deprived of excess o moisture, and then spread in a thin layer on a travellin conveyor where it is subjected to the action of a curren of hot air of progressively increasing temperature, th vapours given off by the garbage being conducted to th furnace supplying the heated air.—W. P. S.

Water; Apparatus for producing distilled ——. Bleicken, Gross-Borstel, Germany. U.S. Pat. 1,102,131 June 30, 1914. Date of appl., Jan. 19, 1914.

Leeuwenhoek's reaction	Very weak.	Strongly positive		

A sample of bark from branches and two samples of mixed bark from stems and branches contained respectively: total alkaloids, 1·77, 2·64, 1·65; tannins, 14·74, 16·78, 13·9; and water, 9·7, 9·15, 8·35%.—A. S.

Organic bases; Displacement-curves of some ——. Application to the determination of some alkaloids. R. Goubau. Bull. Acad. roy. Belg., Classe des sci., 1914, 63—90. Chem. Zentr., 1914, 2, 172.

THE displacement curve of a base is defined as the curve representing the change of electrical conductivity of a solution of a salt of the base on addition of increasing quantities of a second base capable of completely displacing the first base from its salt. In applying the method a known excess of hydrochloric acid is added to a known quantity of the base, the solution is diluted with water or alcohol, if necessary, its electrical conductivity determined at a definite temperature, then $N/1$ or $N/10$ sodium hydroxide added in 0·1 c.c. portions and the alteration of conductivity observed. The curve obtained consists of three portions, the first representing the neutralisation of the excess of acid, the second being the displacement-curve proper and the third representing the increase of conductivity due to excess of sodium hydroxide. The form of the displacement-curve varies according to the character of the base, and the method may be applied to the determination of small quantities of alkaloids. Experiments in this direction were made with cocaine, homatropine, atropine, coniine, nicotine, aconitine, pilocarpine, morphine, codeine, quinine, quinidine, cinchonidine, cinchonine, strychnine, and brucine.—A. S.

entiopicrin and gentianose in the fresh roots of purple gentian. M. Bridel. J. Pharm. Chim., 1914, 10, 62—66.

ABOUT 1·3% of gentiopicrin and 0·4% of gentianose were btained in crystalline form from the fresh roots of *entiana purpurea*, L.—F. SHDN.

emon-grass oil from India. Bull. Imp. Inst., 1914, 12, 222—225.

OCHIN lemon-grass oil sold in the United Kingdom has ecently begun to show signs of insolubility in 70 and 0% alcohol (see this J., 1913, 306, 623). Of 5 samples f commercial Cochin oil three (Nos. 3, 4 and 5) were nsoluble in 5 vols. of 70% alcohol, the other two (Nos. 1 nd 2) dissolved to a clear solution in 2 vols. and 1 75 vols. espectively. Three of the oils gave the following figures :—

	No. 1.	No. 2.	No. 3.
p. gr. at 15° C.	0·901	0·917	0·908
otation a_D	—5° 35′ (at 21°)	—	about —2° (at 19°)
ldehydes (by bisulphite) %	68·5	77	73

wo varieties of grass—the "red-" and "white-" temmed—are distilled in North and Central Travancore. il from the white-stemmed variety more closely resembled citronella than lemon-grass oil. The oil from red-emmed grass had the sp. gr. at 15° C., 0·925, and contained aldehydes, 71·5%. It was not soluble in 5 vols. f 70% alcohol to a clear solution, but was soluble in ·8 vol. or more of 80% alcohol, and gave a somewhat urbid solution with 5 vols. The oil was separated by eam distillation into a readily volatile portion, 65%, nd a residual viscous oil, 35%; the readily volatile oil as soluble in 2·4 vols. of 70% alcohol, the residual oil as insoluble in 12 vols. The insolubility of some Cochin ls may therefore be due to distillation being carried too r.—R. G. P.

etiver oil from Fiji. Bull Imp. Inst., 1914, 12, 225—227.

HE oil was viscous and yellowish-brown and had the . gr. at 15° C., 1·018; and saponif. value, 47. It was luble in 1½ vols. of 80% alcohol, becoming turbid with 3 vols. or more. It resembled "heavy" vetiver oil as distilled in Europe rather than "light" Réunion oil. Its value is uncertain, and the demand is fully met by existing supplies.—R. G. P.

Ylang-ylang oils from the Seychelles and Mauritius. Bull. Imp. Inst., 1914, 12, 228—232.

Two samples from the Seychelles and one from Mauritius gave the following results :—

	Seychelles.			Mauritius.
	1.	2.	2. after keeping for 3 yrs.	
Sp. gr. at 15° C.	0·9567	0·9200	0·9250	0·9883
Rotation, a_D ..	—28° 5′ at 20°	—30° at 21°	—28° 36′ at 24°	—30° at 20°
Acid value	3·3	4·2	2·6	7
Ester value ..	126·0	42·2	53·5	173
Saponif. value	129·3	46·4	56·1	180
Saponif. value after acetylation	181	—	—	211
Solubility in 90% alcohol	Clear with less than 0·8 vol., turbid with 0·8 or more	Soluble in 1 vol., turbid with more	Soluble in ½ vol., turbid with 1 vol. or more	Clear with 0·1 to 2·5 vols., turbid with more

Sample 1 from the Seychelles closely resembled first-grade Manila oil in chemical character although the odour was somewhat pungent. The Mauritius sample would probably only fetch 3s.—4s. per oz., over-production having rendered the sale of all but high-grade oil unremunerative. —R. G. P.

Clove oil from Mauritius. Bull. Imp. Inst., 1914, 12, 232—233.

TRIAL distillations in Mauritius gave yields of only 11·5 and 10·2% of oil respectively against the 15 to 18% usually obtained in Europe; the low yield may be due to high moisture content. Two samples of oil had sp. gr. at 15° C., 1·061 and 1·067; and rotation, a_D at 22° = —10′ and —5′. They contained eugenol 89 and 95% and were soluble in 1·5 vols. or more and in 1·25 vols. or more respectively of 70% alcohol. Though inferior in colour and aroma to oil distilled in United Kingdom, the oils were of good quality and would meet with ready sale.—R. G. P.

Clove leaf oils from Mauritius. Bull. Imp. Inst., 1914, 12, 233—235.

THREE samples had sp. gr. from 1·059 to 1·062 and contained 90 to 91% of eugenol. The oils were of dark colour but would be saleable at about 3s. 9d. per lb. as a source of eugenol for the manufacture of vanillin. In Mauritius only 1·62% yield of oil was obtained from clove leaves; leaves from the Seychelles distilled at the Imperial Institute yielded 4·5%.—R. G. P.

Sandal wood oil from Mauritius. Bull. Imp. Inst., 1914, 12, 235—237.

THREE samples of oil distilled from the heartwood (1 and 2) and sapwood (3) of *Santalum album* gave the following results :—

	1.	2.	3.
Sp. gr. at 15° C.	0·9788	0·9804	0·9814
Rotation, a_D at 20° C. ..	—21° 19′	—20° 19′	—20° 36
Acid value	1·4	1·7	2·2
Saponif. value	4·7	3·9	2·8
Saponif. value after acetylation	199·7	203·3	203·0
Santalol % calcd. from saponif. value after acetylation	93·1	95·0	94·9

All three oils were soluble in 5½ vols. or more of 70% alcohol at 15° C. They contained a satisfactory amount of santalol but were somewhat dark-coloured. They would probably sell readily at about 20s. to 21s. per lb. in London.—R. G. P.

Essential oils; Constituents of ——. *Action of high temperatures on the sesquiterpenes; formation of terpinene; artificial preparotion of the blue compound found in many essential oils.* F. W. Semmler and W. Jakubowicz. Ber., 1914, **47**, 2252—2259.

The condensation of such substances as isoprene, terpenes, and sesquiterpenes can be effected by heating in sealed tubes to about 275° C. (this J., 1914, 765), whilst at 330° C. the converse reaction takes place. Heating to the latter temperature resolves β-gurjunene into a terpinene, $C_{10}H_{16}$, and diterpenes. α-Gurjunene similarly yields a hydrocarbon, $C_{10}H_{16}$, a diterpene, and a blue compound which boils between 140° and 180° C. at 11 mm. and is decolorised by distillation over sodium. Cedrene and caryophyllene yield hydrocarbons, $C_{10}H_{16}$. Cadinene on the other hand yields a small proportion of a monocyclic sesquiterpene, whilst the greater portion remains unchanged.—F. Shdn.

Borneol in the presence of metals and metallic oxides; Catalysis of ——. J. Aloy and V. Brustier. J. Pharm. Chim., 1914, **10**, 49—51.

Borneol was heated in a tube partly filled with finely divided copper in such a manner that the vapours passed over the metal. At about 300° C., dehydrogenation took place with the formation of camphor, the transformation being complete when the vapour was passed slowly. Higher or lower temperatures led to diminished yields. With nickel at 350° C., also, camphor was formed, whilst a small yield was obtained with iron. Using thorium oxide as catalyst at 350° C. a mixture of terpene hydrocarbons containing pinene was obtained.—F. Shdn.

Patents.

Dihalogen paraffins; Manufacture of ——. F. E. Matthews and H. J. W. Bliss, London. Eng. Pat. 15,048, June 30, 1913.

A mixture containing olefine hydrocarbons and saturated hydrocarbons is fractionated so that the olefine hydrocarbons in each fraction are chiefly such as have the same number of carbon atoms in the molecule, and the fractions are treated with only sufficient halogen to effect the saturation of the unsaturated hydrocarbons, when the dihalides can be separated by fractional distillation.—F. Shdn.

Butadiene and homologues thereof; Manufacture of ——. W. H. Perkin, Manchester, and F. E. Matthews, London. Eng. Pat. 15,049, June 30, 1913.

Butadiene or its homologues are obtained by subjecting olefines to the action of oxidising substances or substances which combine with hydrogen at elevated temperatures, with or without the use of catalysts.—F. Shdn.

Mononitro- and dinitroaminobenzene-arsinic acids or substitution derivatives thereof substituted in the amino-group; Manufacture of ——. C. F. Boehringer und Söhne, Mannheim-Waldhof, Germany. Eng. Pat. 29,546, Dec. 22, 1913. Under Int. Conv., Dec. 24, 1912.

Compounds are formed by the interaction of ammonia or ammonia derivatives and 4-chloro-3-nitrobenzene-1-arsinic acid or 4-chloro-3.5-dinitrobenzene-1-arsinic acid. The compounds obtained from 4-chloro-3-nitrobenzene-1-arsinic acid can be further nitrated.—F. Shdn.

Therapeutic agents [derivatives of aurothiosulphuric acid] in the treatment of tuberculosis and syphilis; Process of manufacturing new compounds suitable as ——. Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. Eng. Pat. 1869, Jan. 23, 1914. Under Int. Conv., Jan. 31, 1913.

Aurothiosulphates of organic bases are obtained by allowing the latter or their salts to interact with aurothiosulphuric acid or its salts. The ethylenediamine compound is a white crystalline powder, easily soluble in wate but soluble with difficulty in alcohol.—F. Shdn.

Esters of the terpene series; Process for preparing therapeutically-active ——. Kalle und Co. A.-G. Ger. Pat 273,850, Oct. 8, 1912.

Bromo-derivatives of alkyl- or aryl-acetic acids of th general formula, RR′CBr.COOH, where R and R represent an alkyl or aryl residue, are condensed in th usual manner with terpene alcohols. The resulting ester possess soporific properties resembling those of the bromo dialkylacetamides.—T. F. B.

Acetylsalicylic acid; Process for preparing a compoun [urea salt] of ——. Dr. Schütz und Co. Ger. Pa 274,046, April 10, 1913.

Equimolecular quantities of acetylsalicylic acid and ure are dissolved in high per cent. alcohol or other suitabl solvent at 60° C., and the combined solutions are evaporate at as low a temperature as possible, preferably in vacuum. The product consists of pure urea acety salicylate, uncontaminated with the salicylate; it may l used in medicine on account of its antirheumatic, analgesi and antiuratic properties.—T. F. B.

α-Bromo-isovalerylurea; Process for preparing a compou [acetylsalicylate] of ——. Knoll und Co. Ger. Pa 274,349, Aug. 2, 1912.

Molecular proportions of acetylsalicylic acid and bromo-isovalerylurea are made to react by melting the together, with or without addition of a solvent. T product exhibits the sedative properties of the ur compound together with all the characteristics of salicy acid compounds, but without the sudorific effects as ciated with acetylsalicylic acid.—T. F. B.

α-Bromoisovalerylurea: Process for preparing ——. Kr und Co. Ger. Pat. 275,200, July 27, 1912.

An α-bromo-isovaleryl halide is converted into the cyaa by treatment with a metallic cyanate in presence of indifferent diluent, and the cyanate is treated w ammonia to produce α-bromo-isovalerylurea. A gene process has been worked out for the preparation of a cyanates by treating acyl halides with metallic cyana in presence of a diluent; when silver or mercury cyan (the latter prepared from mercurous nitrate and potassi cyanate) are used, the acyl cyanates are nearly alw obtained in quantitative yield.—T. F. B.

C-Allyl-o-hydroxybenzoic acids; Process for prepa derivatives of ——. Farbenfabr. vorm. F. Bayer Co. Ger. Pat. 274,047, May 23, 1913.

C-Allyl-o-hydroxybenzoic acids are treated acylating agents, and the acyl derivatives are conve into salts. The products possess antipyretic, antineura and antirheumatic properties; in this respect they more active than the corresponding acylsalicylic a —T. F.

Alkyloxyaryl-, dialkyloxyaryl-, and alkylenedioxyaryl-aminopropanes or their N-monoalkyl derivatives; Process for preparing ——. E. Merck. Ger. Pat. 274,350, Dec. 24, 1912.

Unsaturated propylene compounds of the general formula, $R.CH_2.CH:CH_2$ or $R.CH:CH.CH_2$ (where R is alkoxyaryl, dialkoxyaryl, or alkylenedioxyaryl) are treated with hydrogen halides, and the products are treated with ammonia or a primary aromatic amine. In the treatment with hydrogen halide, the halogen atom attaches itself to the unsaturated carbon which is nearest to the benzene nucleus.—T. F. B.

Trichloroethylene from acetylene tetrachloride; Process for preparing ——. Chem. Fabr. Buckau. Ger. Pat. 274,782, Dec. 25, 1912.

Acetylene tetrachloride can be converted into trichloroethylene without the formation of hexachlorobenzene, by passing its vapour over a catalyst in presence of thorium oxide at a temperature not exceeding 390° C.—T. F. B.

Cyclohexane and its homologues; Process for purifying ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 274,920, May 18, 1913.

The impurities are removed from crude cyclohexane and its homologues by treatment with liquid sulphur dioxide or with solutions of sulphurous acid. Pure cyclohexane constitutes the upper layer, whilst the impurities (unsaturated hydrocarbons, etc.) pass into the sulphur dioxide layer and can easily be separated from it.—T. F. B.

Saponin; Process for preparing primary decomposition products of ——. F. Hoffmann-La Roche und Co. Ger. Pat. 275,048, Oct. 19, 1913. Addition to Ger. Pat. 267,815 (see this J., 1914, 220).

Saponin is treated with hydrogen peroxide solutions at temperatures below 100° C. This process has the advantage that the liquid remains colourless, and the products, which required ten to fifteen days to prepare according to the principal patent, can by this means be obtained in a single day.—T. F. B.

Acetic acid and alcohol from coal, lignite, etc.; Process for producing ——. J. Behrens. Ger. Pat. 275,049, Feb. 21, 1913.

The ethylenic compounds isolated from distillation-gases are mixed with carbon dioxide and heated to about 400° C., and the aldehyde thus produced is oxidised or reduced. Yields of about 20 grms. of alcohol or 26 grms. of acetic acid were obtained from the ethylenic compounds extracted from 1000 litres of illuminating gas by means of sulphuric acid. About 75% of the ethylenes is converted into aldehyde by this process.—T. F. B.

Hexamethylenetetramine-methyl borate; Process for preparing ——. K. H. Schmitz. Ger. Pat. 275,092, Aug. 23, 1913. Addition to Ger. Pat. 266,788 (see this J., 1914, 43).

Hexamethylenetetramine is heated with boric acid or methyl borate with or without addition of formaldehyde or a mixture of ammonia solution with formaldehyde or ts polymerides; the same product is obtained by boiling an aqueous solution of hexamethylenetetramine borate for a long time. The resulting methyl borate has the composition, $C_6H_{12}N_4.CH_3OH.5HBO_2$, and is much more stable than hexamethylenetetramine borate. It is applicable to medicine. (See also Ger. Pats. 269,746 and 270,486; this J., 1914, 375, 439.)—T. F. B.

6-Chloro-1-methyl-3-hydroxybenzene-4-carboxylic acid; Process for preparing ——. J. D. Riedel A.-G. Ger. Pat. 275,093, March 20, 1913.

p-Chloro-*m*-cresol-sodium ($ONa : CH_3 : Cl = 3 : 1 : 6$) is heated to a high temperature under pressure, in presence of carbon dioxide, preferably at 160°—180° C. An almost quantitative yield of 6-chloro-1-methyl-3-hydroxybenzene-4-carboxylic acid is obtained. In contrast with *p*-chlorophenol-*o*-carboxylic acid, which has not been found to possess therapeutic value, the new compound has powerful antiseptic properties.—T. F. B.

Anhydrides of monobasic carboxylic acids; Process for the manufacture of ——. E. C. R. Marks, London. From Naamlooze Vennootschap Fabriek van Chemische Produkten, Schiedam, Holland. Eng. Pat. 12,042, May 23, 1913.

See Fr. Pat. 461,540 of 1913; this J., 1914, 219.—T. F. B.

Para-nitrophenylureas; Manufacture of ——. Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. Eng. Pat. 17,123, July 25, 1913. Under Int. Conv., July 25, 1912.

See Addition of July 11, 1913, to Fr. Pat. 459,885 of 1913; this J., 1914, 219.—T. F. B.

Salts of acetylsalicylic acid; Process for preparing ——. O. Gerngross, Grünewald, and H. Kast, Charlottenburg, Germany. Eng. Pat. 24,849, Oct. 31, 1913. Under Int. Conv., Oct. 31, 1912.

See Fr. Pat. 464,081 of 1913; this J., 1914, 439.—T. F. B.

Chlorine derivatives of the amyl series; Producing ——. F. Webel, Mannheim, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 1,098,858, June 2, 1914. Date of appl., Feb. 27, 1913.

See Eng. Pat. 19,764 of 1912; this J., 1913, 550.—T. F. B.

Isoprene; Producing ——. F. Webel, Mannheim, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 1,098,859, June 2, 1914. Date of appl., Feb. 27, 1913.

See Eng. Pat. 13,327 of 1913; this J., 1913, 924.—T. F. B.

Morphine; Process of manufacturing alkyl-ethers of ——. M. C. Traub, Basle, Switzerland, Assignor to J. and D. McKesson, Chappaqua, and W. H. Wickham, G. C. and I. McKesson, and H. D. Robbins, New York. U.S. Pat. 1,100,998, June 23, 1914. Date of appl., May 6, 1912.

See Eng. Pat. 22,611 of 1911; this J., 1912, 557.—T. F. B.

Salts of high molecular fatty acids containing arsenic and a halogen. E. Fischer, Berlin, Assignor to Synthetic Patents Co., New York. U.S. Pat. 1,101,733, June 30, 1914. Date of appl., Aug. 12, 1913.

See Eng. Pat. 10,379 of 1913; this J., 1914, 438.—T. F. B.

Iron salts of high molecular fatty acids containing arsenic and a halogen. E. Fischer, Berlin, Assignor to Synthetic Patents Co., New York. U.S. Pat. 1,101,734, June 30 1914. Date of appl., Aug. 12, 1913.

See Ger. Pat. 271,158 of 1913; this J., 1914, 503.—T. F. B.

Manufacturing highly active extracts rich in enzymes and nitrogenous matters for use in baking, for medicinal and other purposes. Eng. Pat. 13,928. *See* XIXa.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Patent.

Photographs; Process of making coloured ——. R. Fischer, Steglitz, Germany. U.S. Pat. 1,102,028, June 30, 1914. Date of appl., Jan. 27, 1913.

See Ger. Pat. 253,335 of 1912; this J., 1913, 47.—T. F. B.

XXII.—EXPLOSIVES; MATCHES.

Explosions: Report of Board of Trade enquiry into electric main ——. [Cd. 7481.]

Serious explosions on ignition of vapour generated by short circuits in underground cables have not occurred with alternating current, or with concentric, lead-covered paper insulated, or three-core cables, or with cables laid solid in pitch compound, but have occurred in the case of cables insulated with vulcanised bitumen, and drawn into bitumen casings or laid solid in bitumen. As bitumen has been much more extensively used than pitch compound, however, a direct comparison is not possible. Bitumen and pitch mixed with whinstone dust were distilled: the limits of inflammability of the gases were narrower for bitumen than for pitch compound, but the difference disappeared if the gases were cracked at 1000° C.; no pyrophorous carbon was formed. It is recommended that where the solid system is employed, wood troughing should be used only in suitable soil, with mains in separate troughs two inches apart and packed between with earth or sand, and not below impervious pavements or close to houses, that existing, or new bends should be eased off and straights filled and cooled first and that services should be taken into houses, preferably by armoured cables, in such a manner that gas cannot enter.—O. E. M.

Patents.

Match-splints; Process of treating ——. W. G. Wey, Barberton, Ohio, Assignor to The Diamond Match Co., Chicago, Ill. U.S. Pat. 1,098,700, June 2, 1914; date of appl., May 29, 1913.

Match sticks are dipped at 121° C., in paraffin wax, in which phosphorus has been dissolved.—G. W. McD.

Process for removing bromate from chlorate. Ger. Pat. 274,471. *See* VII.

XXIII.—ANALYTICAL PROCESSES.

Lacmosol, the sensitive component of the indicator lacmoid. R. Hottinger. Biochem. Zeits., 1914, **65**, 177—188.

Commercially pure lacmoid is a mixture essentially of three constituents, all of which respond as indicators: these are (*a*) "lacmosol" (about 20%), (*b*) "lacmoid" (80%), and (*c*) a yellowish-red substance. The first, which is the most sensitive, is distinguished (from *b* and *c*) by its solubility in ether and (from *c*) by its insolubility in acidified strong brine; it is best prepared by heating 10 grms. of resorcinol with 2 c.c. of concentrated sodium nitrite solution at 105° C. until the depth of tint imparted by the product to water becomes constant (about 40 mins.), dissolving the mixture in 50 c.c. of water, pouring into 1 litre of strong brine (acidified with hydrochloric acid), and, after a time, filtering off the precipitate formed, washing with brine, dissolving in ammonia, and again precipitating with acid brine. The well-washed precipitate is dissolved in a little acetone, the solution poured into 30 vols. of ether, allowed to stand, any precipitate filtered off and rejected, the ether distilled off from the filtrate, the residue dissolved in acetone, and the process repeated until no further precipitate forms with ether. The yellowish-red constituent is removed by repeated precipitation from alkaline solution, and the powdered indicator finally extracted with ether in a Soxhlet apparatus. Lacmosol is superior to commercial lacmoid in sensitiveness and sharpness of colour change; it may be used in aqueous solution or dissolved in ether, alcohol, or acetone, and has been found specially suitable in the determination of nitrogen by Kjeldahl's method.
—F. Sodn.

Manganese sulphide and the determination of manganese. A. Villiers. Comptes rend., 1914, **159**, 67—69.

In analytical work manganese sulphide may be produced as an unstable rose-coloured, a stable rose-coloured, and a green modification respectively. The last is the densest form and is most suitable for separations; it is produced by the dehydration, with liberation of heat, of the first form. To obtain the green variety foreign salts should be absent and the solution should be rendered ammoniacal before the addition of ammonium sulphide.—T. St.

Titanium and chromium; Volumetric determination of —— *by means of a modified reductor.* C. Van Brunt. J. Amer. Chem. Soc., 1914, **36**, 1426—1429.

The reductor used by Shimer and Shimer (this J., 1912, 955) for the determination of titanium has the disadvantage that the solution passes very slowly through the long thin tube. The author uses a reductor of the usual form (containing a column of well amalgamated, coarse granulated zinc, 2·5 cm. in diameter by 20 cm. in height) wound with a few feet of resistance ribbon in series with a lamp or other resistance, so that the solution may be boiled. In using the reductor, the stopcock at the bottom is closed, and the tube is partly filled with hot 5% sulphuric acid, the solution to be reduced then being added. A rubber stopper carrying a funnel tube with a stopcock, and a small vent tube is placed in the top of the reductor, and the contents of the latter are heated and kept nearly boiling for 10—20 mins. The solution is then expelled, by the internal pressure, through a tube to the bottom of the vessel beneath, which contains excess of acidified ferric ammonium sulphate. More acid is admitted to the reductor and forced out as before, the operations being carried out without access of air to the space above the zinc. The washing is completed with 1% sulphuric acid with the top of the reductor open, and the reduced iron is titrated with permanganate, the amount of titanium (or chromium) being calculated therefrom.—L. E.

Gas analyses by fractional distillation at low temperatures. G. A. Burrell and F. M. Seibert. J. Amer. Chem. Soc., 1914, **36**, 1537—1548 (cp. Lebeau and Damiens, this J., 1913, 126, 186, 352).

This method serves for separating the individual paraffin hydrocarbons of natural gas. Methane (together with any nitrogen) is quantitatively removed by cooling the sample to —185° to —190° C., removing the gas that distils at this temperature, volatilising the liquid residue and twice repeating the liquefaction, etc. Ethane is similarly removed from the methane-free residue at —145° to—125° C., but since the distillate contains some propane, it is finally treated at —155° to —140° C. Propane is removed at —125° to —110° C. and finally freed from some accompanying butane by distillation at —135° to —120° C.—L. E.

Mannitol; The methods for the quantitative determinatio of ——. J. Smit. Z. anal. Chem., 1914, **53**, 473—490

In using the method described in this J., 1914, 769 compounds and derivatives of ammonia are eliminate by boiling with alkali, and the solution is then neutralised Amino-acids, when containing several free amino-group must either be precipitated with phosphotungstic acid or else converted by the action of nitrous acid into hydroxy-acids; the latter are extracted by shaking the solution with ether in presence of a little sulphuric acid. Tartaric acid is removed by precipitation as calcium or lead tartrate. As glycerol exerts a solvent action on copper it has to be determined: the method depending upon the solubility of glycerol in a mixture of absolute alcohol (1 vol.) and dry ether (1½ vols.) can be applied, since mannitol is insoluble in this mixture. The method is not readily applicable to mixtures containing such nearly related substances as sorbitol, dulcitol, etc.—J. R.

PATENTS.

recipitates; Machine for washing ——. H. E. Elson, Masontown, Pa. U.S. Pat. 1,097,708, May 26, 1914; date of appl., Nov. 18, 1913.

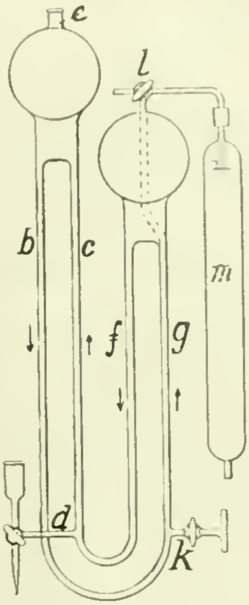
UNNELS are mounted in a rotating stand so that they can ccessively be brought into position below a tube which elivers the liquid used to wash the precipitate.
—G. W. McD.

ases; Method of, and apparatus for sampling ——. E. W. Brown, Elyria, Ohio. U.S. Pat. 1,100,171. June 16, 1914; date of appl., Oct. 7, 1912.

MEASURED sample removed from the main at the same locity as the gas passing through the main is led through weighed filter to determine the amount of solid matter esent.—G. W. McD.

s-analysis apparatus for the treatment of gases with measured quantities of a liquid reagent. K. Heinemann. Ger. Pat. 273,726, June 6, 1913.

HE apparatus is shown in the figure and is especially itable for the determination of sulphur dioxide in burner gases or of ammonia in gaseous mixtures. The reagent is introduced through *d*, the gas to be tested through *k* or *l*, and an inert gas, such as air, through *e* or *d*, whereby a vigorous circulation of gas and liquid through the tubes, *g*, *f*, *c*, *b*, is produced, similar to that in apparatus of the "emulseur" type. The residual unabsorbed gas may be transferred through *l* to the measuring vessel, *m*.
—A. S.



Inflammable (reactive) substances in gaseous mixtures; Determination of ——. W. H. Eyermann. Ger. Pat. 273,980, March 23, 1913.

THE quantity of the inflammable constituent is determined by measuring the difference in temperature of the gaseous mixture before and after a reaction (*e.g.*, combustion) has taken place. The apparatus is so constructed that the hot gases leaving the reaction chamber serve to preheat the incoming gases, and both the reaction chamber and preheater are provided with heat-insulating jackets. The reaction-chamber is fitted with baffles to effect thorough mixing of the gases and equalisation of the temperature therein.—A. S.

Samples of powdered substances or liquids; Means for taking ——. T. Roberts, Bolton. U.S. Pat. 1,101,568, June 30, 1914. Date of appl., Oct. 19, 1912.

SEE Ger. Pat. 262,896 of 1913; this J., 1913, 928.—T. F. B.

Trade Report.

Measures affecting the exportation of goods in various countries. Board of Trade, August, 1914.

THE exportation of the following articles is prohibited:—

Belgium.—Arms and munitions of war, substances used for the manufacture of explosives, copper, brass, sulphur, nitric acid, lead, German silver, zinc, and pewter, also lubricating oils, burning oils, and "essences" for motive power.

France.—Benzol, meat preserves, cotton waste, dynamite and similar explosives, mineral oils of all kinds, nitrate of soda, raw and dressed hides and skins, lead, gunpowder, guncotton, nitroglycerin and the like, saltpetre, and sulphur.

Austria-Hungary.—Leather, sulphur and sulphuric acid, saltpetre and nitric acid, calcium carbide, nitrotoluol, glycerin, acetone, sulphuric anhydride, picric acid, ammunition and explosives.

Germany.—1. Ammunition and explosives, iron and steel, tin, aluminium, nitrate of potash, ammonia, soda, nitric acid, camphor, acetate of lime, acetone, acetic ether, ethyl ether, carbolic acid, benzol, nitrated cotton and cellulose, picric acid, nitrate of barium, phosphorus, toluol, cresol and metacresol, turpentine oil, di- and tri-nitrotoluol, diphenylamine, sodium oxalate, antimony, mercury, wolfram, and colophony.

2. Raw materials for war materials as follows: Iron ore, pyrites, copper, coal, coke, mineral oils, tar oils, textiles, hides and skins, wood pulp, caoutchouc, gutta percha, and balata.

3. Surgical dressings and medicinal products as follows: Pure carbolic acid, mercury, corrosive sublimate, iodine, iodides, iodoform and chloroform, pyrazolone, phenyl-dimethyl and derivatives, such as pyramidon, powdered opium, morphia and its salts, phosphoric codein, para-formaldehyde, quinine sulphate and hydrochloride, "arekoline," salvarsan, bacteriological apparatus, material for bacteriological cultures, vaccines and serums.

Also animal products, food supplies, automobiles, mineral oils, tar oils and all oils produced therefrom.

Great Britain.—Acetone, benzol, carbons, copper, copper ore, cotton suitable for manufacture of explosives, cotton waste, creosote, dimethylaniline, fulminate of mercury, gunpowder, nickel and ferro-nickel, oil (blast furnace), tar oil, oil fuel, shale oil, petroleum oil and spirit (including Shell spirit), silk, surgical bandages and dressings, toluol, zinc.

The exportation of the following articles is prohibited to all foreign ports in Europe and on the Mediterranean and Black Sea, except those of France, Russia (except the Baltic ports), Spain and Portugal:—Aluminium and its alloys; armour plates; asbestos; coal (steam and large); engine and boiler packings; explosives of all kinds; fuel (manufactured); indiarubber sheet (vulcanised); manganese; mica; mineral jellies; molybdenum; nitrates of potassium and ammonium; nitrotoluol; nitric acid; picric acid and its components; saltpetre; sulphur; sulphuric acid; tin; tin plates; tungsten; vanadium; alcohol (as covering rectified spirits); glycerine, crude and refined; lead in all forms; saltpetre; nitrate of sodium; guncotton; carbolic acid; alcohols, ethylic; alcohols, methylic; alkaline iodides; belladonna and its preparations and alkaloids; bismuth and its salts; boric acid; bromine and alkali bromides; castor oil; chloroform; cinchona bark, quinine and its salts; coca and its preparations and alkaloids; collodion; corrosive sublimate; cresol and all preparations thereof (including cresylic acid) and nitro-cresol; digitalis and its preparations; ether; ethyl chloride; formic aldehyde; henbane and its preparations; iodine and its preparations; lysol; mercury and its salts and preparations; morphia and other alkaloids of opium; nux vomica and its alkaloids and preparations; opium and its preparations; paraffin, soft; protagol; salicylic acid and salicylates; salvarsan; all fine chemicals; sugar, all kinds; glucose; molasses and invert sugar.

Books Received.

Industrial Resources of the Philippine Islands. Bureau of Science, Manila. Gratis.

A pamphlet, 9 ins. by 4 ins., issued by authority of the Philippine Government to show the result of the work of the Bureau of Science. Detailed accounts of the work are to be found in the Philippine Journal of Science, reference to which is made throughout the pamphlet. The work is divided as follows: Chemical technology limestone and silicate industries, mineral resources bacteriology, botany, entomology, fisheries, etc. Unde the heading "chemical technology" are discussed:—Sugar, nipa palm (this J., 1914, 656); palm brandy (ib 1911, 1133); starch; coconut; vegetable oils; perfume and essential oils (*ib.* 1904, 918; 1909, 906; 1911, 1406 1912, 90); papaya gum; tanning materials (*ib.* 1909 1051; 1911, 437, 969); dyes (*ib.* 1911, 737); paper pul (*ib.* 1906, 863; 1907, 274, 941; 1910, 1450). Alum i the form of alunite is found in considerable quantity, coa is abundant (this J., 1907, 1040; 1909, 15), guano occur in limestone caves in nearly every province (this J., 1913 100); medicinal plants grow luxuriantly, but only one *Strychnos Ignatii*, is exported (*ib.* 1907, 274); the rest such as the castor oil and croton oil plants, kamala, an datura are not utilised. Guttapercha is exported (thi J., 1912, 1138).

Mines and Quarries: General Report, with Statistic 1913. Part I. Divisional Statistics. [Cd. 7,452 Wyman and Sons, Fetter Lane, E.C. Price 7d.

This return contains statistics of the number of perso employed, the output of minerals, and the accidents mines and quarries in the United Kingdom, arrange according to the inspection districts. The total outp of the undermentioned minerals in the United Kingdo in 1913, as compared with 1912, was as follows:—

—	1912.	1913.
	Tons.	Tons.
Coal	260,416,338	287,430,473
Iron ore	13,790,391	15,997,328
Clays and shale	12,808,950	13,859,821
Limestone (other than chalk)	11,500,660	12,740,664
Igneous rock	6,638,215	7,098,493
Chalk	4,285,412	4,858,126
Sandstone	3,839,567	3,977,303

Die Nitrocellulosen. Ihre Bildungsweisen, Eig schaften und Zusammensetzung. Von Dr. Haeussermann. Em. Professor der Technisch Hochschule, Stuttgart. Friedr. Vieweg und So Verlagsbuchhandlung. Braunschweig. 1914. Pr M. 1.60.

This volume ($9\frac{1}{4}$ by $6\frac{1}{4}$ ins.) contains 34 pages of subje matter classified as follows:—I. Behaviour of cott cellulose with nitric acid and nitro-sulphuric ac II. Guncotton and collodion cotton. III. Nitrohyd and nitro-oxy-celluloses. IV. Nitrostarch and nitro-deri tives of dextrins from cellulose. V. Nitrous esters cellulose.

Filters and Filter Presses for the Separation Liquids and Solids. From the German of F. Bühler. With additional matter relating to Theory of Filtration and Filtration in Su Factories and Refineries, by J. J. Easti F.I.C., A.R.S.M. Norman Rodger, St. Dunst Hill, London, E.C. 1914. Price 12s. net.

Volume ($9\frac{3}{4}$ by $6\frac{7}{8}$ ins.) containing 167 pages of subj matter with 327 illustrations, an appendix with classi references to patents taken out from 1901 to date (pa 168 to 179), and alphabetical indexes (pages 180 to 1 of subjects and names. The text is classified as follows Part I. (i), Filters with loose filtering layer. (ii), Fil with woven or felted filtering mediums. (iii), Fil with rigid filtering layer. (iv), Separating appar without filtering layer. Part II. (i), Presses with pr cloths. (ii), Presses with press-baskets. (iii), Pre with heating or cooling. Part III. (i), Filtration aids to filtration as applied to the sugar industry. Theory of filtration. (iii), Sugar filtration. (iv), Speci tions of sundry filter press patents.

ubject List of Works on the fine and graphic Arts in the Library of the Patent Office. New Series BM—BZ. The Patent Office, 25, Southampton Buildings, London, W.C. Price 6d. each.

feature of the New Series of Subject Lists, issued uides to the contents of the Library, is that the headings ontain certain marks indicating the location of classes f books in the Library. This work contains 224 small vo pages.

ubject List of Works on Photomechanical printing and photography in the Library of the Patent Office. New Series CA—CC. The Patent Office, 25, Southampton Buildings, London, W.C. Price 6d.

ontains 121 small 8vo pages.

ubject List of the Works on the Silicate Industries (Ceramics and Glass) in the Library of the Patent Office. New Series CD—CK. The Patent Office, 25, Southampton Buildings, London, W.C. Price 6d.

ontains 84 small 8vo pages.

No. 16, Vol. XXXIII. AUGUST 31, 1914. No. 16, Vol. XXXIII.

Official Notices.

BOARD OF TRADE ANNOUNCEMENT.

The Board of Trade has issued the following announcement :—

"In view of the cessation of imports from Germany and Austria and the fact that there are many articles hitherto imported from these countries of importance, if not of necessity to British manufacturers, information is invited by the Commercial Intelligence Branch of the Board of Trade from importers of such articles, as to their precise nature and quality, in order that steps may be taken to ascertain whether similar goods might be produced in this country, and, if so, where ; or, if not, from what neutral sources they could be obtained."

A Committee has been appointed by the Society of Chemical Industry to report to the Board of Trade on this subject. Communications should be addressed to the Secretary of the Society.

WITHDRAWAL OF PROHIBITION OF CERTAIN EXPORTS.

Attention is called to the notice on page 846, relative to the removal of the prohibition to export certain articles mentioned in the notice in the Aug. 15th issue of the Journal, page 810.

All such Proclamations will be found in the "London Gazette."

PATENTS AND DESIGNS ACT, 1914.

4 and 5 Geo. V. Chap. 18.

An Act to amend section ninety-one of the Patents and Designs Act, 1907.

7th August, 1914.

Whereas by a Convention made at Washington in nineteen hundred and eleven, to which His Majesty was a party, an amendment was made in Article IV. (*a*) of the International Convention for the Protection of Industrial Property made at Paris in eighteen hundred and eighty-three, whereby the rights of priority conferred by that Article on persons who have applied for protection for an invention, design or trade-mark in foreign States were extended to the legal representatives and assignees of such applicants, and it is expedient for the purpose of enabling effect to be given to the first-mentioned Convention that such amendment as hereinafter mentioned should be made in subsection (1) of section ninety-one of the Patents and Designs Act, 1907

Be it therefore enacted by the King's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows :—

1. The rights conferred by section ninety-one of the Patents and Designs Act, 1907, on a person who has applied for protection for any invention, design or trade mark in a foreign State shall extend to his legal representatives and assignees, and accordingly subsection (1) of that section shall have effect as if after the words "any person who has applied for protection for any invention, design, or trade mark in that State" there were inserted the words "or his legal representative or assignee."

2. This Act may be cited as the Patents and Designs Act, 1914 ; and the Patents and Designs Act, 1907, the Patents and Designs Act, 1908, and this Act may be cited together as the Patents and Designs Acts, 1907 to 1914.

PATENTS, DESIGNS, AND TRADE MARKS (TEMPORARY RULES) ACT, 1914.

4 and 5 Geo. V. Chap. 27.

An Act to extend the powers of the Board of Trade during the continuance of the present hostilities to make Rules under the Patents and Designs Act, 1907, and the Trade Marks Act, 1905.

7th August, 1914.

Be it enacted by the King's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows :—

1. (1) The power of the Board of Trade under section eighty-six of the Patents and Designs Act, 1907, and section sixty of the Trade Marks Act, 1905, to make rules and to do such things as they think expedient for the purposes therein mentioned shall include power to make rules and to do such things as they think expedient for avoiding or suspending in whole or in part any patent or licence granted to, and the registration of any trade mark the proprietor whereof is, a subject of any State at war with His Majesty, and any proceedings on any application made by any such person under either of the said Acts and for extending the time within which any act or thing may or is required to be done under those Acts.

(2) In relation to rules made under this Act the provisions of subsection (3) of section sixty of the Trade Marks Act, 1905, shall not apply.

(3) If the rules made under this Act so provide the rules or any of them shall have effect as from the passing of this Act.

2. This Act may be cited as the Patents, Designs, and Trade Marks (Temporary Rules) Act, 1914.

3. This Act and the rules made thereunder shall continue in force during the continuance of the present state of war in Europe, and for a period of six months thereafter and no longer.

PATENTS, DESIGNS, AND TRADE MARKS (TEMPORARY) RULES, 1914.

Dated 21st August, 1914.

Statutory Rules and Orders, 1914. *No.* 1255.

By virtue of the provisions of the Patents, Designs, and Trade Marks (Temporary Rules) Act, 1914, the Board of Trade hereby make the following Rules :—

1. The Board of Trade may, on the application of any person, and subject to such terms and conditions, if any, as they may think fit, order the avoidance or suspension, in whole or in part, of any patent or licence granted to a subject of any State at war with His Majesty, and the Board, before granting any such application, may require to be satisfied on the following heads :—

(*a*) That the patentee or licensee is the subject of a State at war with His Majesty ;

(*b*) That the person applying intends to manufacture, or cause to be manufactured, the patented article, or to carry on, or cause to be carried on, the patented process ;

(*c*) That it is in the general interests of the country or of a section of the community, or of a trade, that such article should be manufactured or such process carried on as aforesaid.

The fee to be paid on any such application shall be that specified in the First Schedule to these Rules, and the fee payable on depositing foreign documents or other papers for the purpose of a record not already provided for under the Patents and Designs Act, 1907, and the Trade Marks Act, 1905, shall be that specified in the First Schedule to these Rules.

An application under this section must be made on Patents Form No. 36 contained in the Second Schedule to these Rules, and shall be filed at the Patent Office.

The Board of Trade may at any time, in their absolute discretion, revoke any avoidance or suspension of any patent or licence ordered by them.

For the purpose of exercising in any case the powers of avoiding or suspending a patent or licence, the Board of Trade may appoint such person or persons as they shall think fit to hold an inquiry.

Any application to the Board for the avoidance or suspension of any patent or licence may be referred for hearing and inquiry to such person or persons who shall report thereon to the Board.

Provided always that the Board of Trade may at any time if in their absolute discretion they deem it expedient in the public interest, order the avoidance or suspension in whole or in part of any such patent or licence upon such terms and conditions, if any, as they may think fit.

2. The Comptroller may, at any time during the continuance of these Rules, avoid or suspend any proceedings on any application made under the Patents and Designs Act, 1907, and the Trade Marks Act, 1905, by a subject of any State at war with His Majesty.

3. The Comptroller may also at any time during the continuance of these Rules extend the time prescribed by the Patents and Designs Act, 1907, or the Trade Marks Act, 1905, or any Rules made thereunder, for doing any act or filing any document, upon such terms and subject to such conditions as he may think fit in the following cases, namely :—

(*a*) Where it is shown to his satisfaction that the applicant, patentee, or proprietor, as the case may be, was prevented from doing the said act, or filing the said document, by reason of active service or enforced absence from this country, or any other circumstances arising from the present state of war, which, in the opinion of the Comptroller, would justify such extension ;

(*b*) Where the doing of any act would, by reason of the circumstances arising from the present state of war be prejudicial or injurious to the rights or interests of any applicant, patentee or proprietor as aforesaid.

4. The term "person" used in these Rules shall, in addition to the meaning given thereto by Section 19 of the Interpretation Act, 1889, include any Government Department.

5. All things required or authorised to be done by to or before the Board of Trade may be done by to or before the President or a Secretary or an Assistant Secretary of the Board, or any person authorized in that behalf by the President of the Board.

All documents purporting to be orders made by the Board of Trade and to be sealed with the seal of the Board or to be signed by a Secretary or an Assistant Secretary of the Board or by any person authorised in that behalf by the President of the Board shall be received in evidence and shall be deemed to be such orders without further proof unless the contrary is shown.

A certificate signed by the President of the Board of Trade that any order made or act done is the order or act of the Board shall be conclusive evidence of the fact so certified.

6. These Rules shall come into operation as and from the Seventh day of August, 1914.

TRADE MARKS (TEMPORARY) RULES, 1914.

Dated 21st August, 1914.

Statutory Rules and Orders, 1914. *No.* 1256.

By virtue of the provisions of the Patents, Designs, an Trade Marks (Temporary Rules) Act, 1914, the Board c Trade hereby make the following Rules :—

1. The Board of Trade may, on the application of an person, and subject to such terms and conditions, if an as they may think fit, order the avoidance or suspensio in whole or in part, of the registration of any Trade Mar the proprietor whereof is a subject of any State at war wit His Majesty, and the Board before granting any suc application, may require to be satisfied on the followi heads :—

(*a*) That the proprietor is the subject of a State at w with His Majesty ;

(*b*) That the person applying intends to manufacture, cause to be manufactured, the goods or any of the in respect of which the Trade Mark is registered ;

(*c*) That it is in the general interests of the country of a section of the community, or of a trade, that t registration of the Trade Mark should be so avoid or suspended.

The fee to be paid on any such application shall be th specified in the First Schedule to these Rules.

An application under this section must be made on Fo T.M. No. 36 contained in the Second Schedule to th Rules, and shall be filed at the Patent Office.

The Board of Trade may at any time, in their absol discretion, revoke any avoidance or suspension of a registration of a Trade Mark ordered by them.

For the purpose of exercising in any case the powers i avoiding or suspending the registration of a Trade Mark Board of Trade may appoint such person or persons as th shall think fit to hold an inquiry.

Any application to the Board for the avoidance r suspension of any registration of a Trade Mark may e referred for hearing and inquiry to such person or pers s who shall report thereon to the Board.

Provided always that the Board of Trade may at time, if in their absolute discretion they deem it exped t in the public interest, order the avoidance or suspen n in whole or in part of any such registration of a Tr Mark upon such terms and conditions, if any, as they y think fit.

2. The term "person" used in these Rules shall r addition to the meaning given thereto by Section 1 of the Interpretation Act, 1889, include any Governm nt Department.

3. All things required or authorised to be done by t before the Board of Trado may be done by to or befor n President or a Secretary or an Assistant Secretary of h Board, or any person authorised in that behalf by h President of the Board.

All documents purporting to be Orders made by the Board of Trade and to be sealed with the seal of the Board or to be signed by a Secretary or an Assistant Secretary of the Board or by any person authorised in that behalf by the President of the Board shall be received in evidence and shall be deemed to be such orders without further proof unless the contrary is shown.

A certificate signed by the President of the Board of Trade that any order made or act done is the order or act of the Board shall be conclusive evidence of the fact so certified.

4. These Rules shall be called the Trade Marks (Temporary) Rules, 1914, and shall come into operation as and from the Seventh day of August, 1914.

REDUCTION OF CHLORATES TO CHLORIDES BY HYDRAZINE SALTS WITH THE AID OF A CATALYTIC SUBSTANCE.

BY W. R. HODGKINSON.

Solutions of alkali, or other chlorates (bromates or odates) and hydrazine salts (nitrate, chloride, sulphate, xalate) may be mixed together in any proportion and oiled without sign of any reaction. No chloride is detectable in the chlorate solution even after 10 hours' oiling. But if a piece of tarnished copper wire or a ragment of CuO be introduced into a cold solution of otassium chlorate and hydrazine nitrate an action mmences at the surface of the solid, nitrogen being volved. If the solution be warmed the action may me violent. When visible action—effervescence—eases either all the chlorate or all the hydrazine salt is nd to have been decomposed.

Quantitative experiments, using equimolecular solutions, how perfect reduction of $KClO_3$ and that the reaction is:

$$2KClO_3+3N_2H_4HNO_3=6H_2O+3N_2+3HNO_3+2KCl.$$

The amount of copper dissolved is very small. Various opper salts produce a like result.

The action may be employed as a method of analysis of hlorates for chlorine (similarly with iodates or bromates), he slight excess of hydrazine salt necessary being afterwards destroyed by permanganate acidified with nitric acid.

Hydrazine sulphate and oxalate do not act nearly so apidly or so well with copper and its salts, probably wing to the formation of relatively insoluble double opper-hydrazine salts.

The action of hydrazine sulphate on alkali chlorate in presence of metallic iron—clean or rusty—or an iron salt, quickly becomes violent, especially with slightly rusty iron. With hydrazine nitrate and oxalate the action of iron is very slow even with warm solutions.

The catalytic action of copper and iron appears to be due to the easy change with these metals from an "ic" to "ous" state. Metals not forming two classes of oxides or salts are found to be inert.

Bichromates, arsenates, persulphates, and osmates are reduced by hydrazine salts, but not to a stage where action on a chlorate is possible. Molybdates and vanadates are particularly active in transferring oxygen from a chlorate to a hydrazine salt.

The changes of colour of the solutions during the action serve as an indication of the completion of oxidation or reduction.

Tungstates and tantalates are not active, although tungstic acid is partly reduced by heating with a hydrazine salt.

The molybdate action is quantitatively perfect, excess of the hydrazine salt being indicated by the blue molybdenum sub-oxide colour. The action in these cases (Mo. V.) depends on the reducibility of these elements to oxides of the types MO or MO_2 which re-oxidise to MO_3 on contact with chlorates, etc. Molybdic acid is reduced by any hydrazine compound to the blue sub-oxide.

A 20 vol. solution of hydrogen peroxide is apparently unaffected by hydrazine nitrate. Copper and iron immediately on contact set up an action whilst alkali molybdate and vanadate are without visible effect.

Perchlorates in solution have so far resisted reduction under any of these circumstances: NH_4ClO_4 and $N_2H_4HNO_3$ may be melted together without decomposition.

Manchester Section.

NOTES ON THE COMPOSITION OF SUNDRY RESIDUAL PRODUCTS FROM SEWAGE.

BY GILBERT J. FOWLER, D.SC., F.I.C., AND JOSEPH CLIFFORD, A.R.C.S. (DUBLIN).

The analyses discussed in the following pages have accumulated over a period of several years, and although there are still sundry lacunæ in the available data, it appears desirable to publish the results so far obtained, as a guide, at any rate, to future work. The aim of the investigation has been to discover whether, by careful analysis of the residual products obtained at various stages of the sewage purification process, any light could be thrown on the nature of the fermentative changes taking place in the solid suspended or colloidal matter of sewage, as distinct from the processes occurring in solution. For this purpose sludges have been examined from various methods of tank treatment at different places and under different conditions, and also so called "slurry" from contact beds at different depths and after differing periods of exposure to air.

For the sake of comparison a number of tables are given from the Reports of the Massachusetts State Board of Health, as summarised in a review of 21 years work given in the Report for 1908.

The samples were in all cases, unless specially stated, washed through a fine meshed sieve (¼ mm.), dried at 100° C., and finely ground before analysis. The carbon and hydrogen determinations were all made by direct combustion with copper oxide, and the nitrogen was determined in some cases by combustion, in others by the Kjeldahl method. In most cases the figures are the mean of two well agreeing analyses. All ratios and percentages of carbon, hydrogen, and nitrogen are calculated on the volatile matter as determined by loss on ignition. In a few cases determination of ether extract and oxygen absorption from permanganate (mgm. per gram) have been made.

The results may be classified under the following heads:—

1. Products obtained under *anaerobic* conditions, *i.e.*, from sedimentation and septic tanks.

2. Products obtained under *aerobic* conditions, viz., from slate-beds and primary and secondary contact beds.

3. Products obtained by "weathering" sundry of the above.

1. *Anaerobic conditions.*

Tables IA, IB and IC, give the analysis of material taken from the inlet and outlet of various septic tanks.

Tables IA and IB show that the finer particles of organic matter are deposited at the outlet end of a septic tank, as evidenced by the higher proportion of organic matter. They also indicate that the digestion of organic matter has proceeded further at the outlet than at the inlet, as is shown by the carbon to hydrogen, and carbon to nitrogen ratios respectively.

In the case of Table IC, containing results from the Hampton Hydrolytic Tank, it is seen that decomposition of the sludge has proceeded further than in the cases of Tables IA and IB, probably owing to more equable conditions.

Table II gives the composition of deposits from various experimental tanks in Calcutta, through which the sewage was allowed to pass 1, 1½, 2 and 3 days, respectively.

From these figures it would appear that the sludge from the hydrolysing chamber of the Hampton Tank has also been fairly completely digested. Inasmuch as the Calcutta sludge was practically free from grease, it may be inferred that the loss of carbon is mainly due in these cases, and in the case of the hydrolytic tank, to cellulose fermentation. This agrees with Dr. Travis's early observations.

Tables III. and IV. show interesting comparative nalyses of sludge from sedimentation and septic tanks at e Davyhulme Works of the Manchester Corporation. he carbon to hydrogen and carbon to nitrogen ratios ring out clearly that under the conditions which prevailed uring the time the tanks were under observation, the ptic tanks were doing little or no work in the digestion organic matter, but were acting as sedimentation tanks.

Aerobic Conditions.—It is interesting to compare with the foregoing results the analyses of products obtained by sedimentation under aerobic conditions. Such a product, *e.g.*, is the deposit accumulating in the Dibdin slate bed, and in Table V. are given sundry analyses of the sludge from the Devizes slate beds, in the conditions occurring on the slate, and after a period of "weathering" out of contact with sewage.

TABLE V.

Aerobic conditions, Devizes, July 8th, 1905.

Where taken.	% Organic matter.	% C. Sample dried at 100° C.	% H. Sample dried at 100° C.	% N. Sample dried at 100° C.	% C. Organic matter.	% H. Organic matter.	% N. Organic matter.	Ratio C : H	Ratio C : N	No. of sample.
nweathered, 1 mm.	56·5	29·21	4·08	3·80	51·7	7·2	6·7	7 : 1	7·7 : 1	5
eathered. 1 mm.	45·0	17·0	2·50	1·99	37·7	5·5	4·4	7 : 1	8·5 : 1	7
nweathered ½ mm.	57·0	30·07	4·24	3·31	52·7	7·4	5·8	7 : 1	9 : 1	6
eathered. ½ mm.	40·1	24·07	2·44	1·83	60·2	6·1	4·5	10 : 1	13 : 1	8

An examination of samples 3 and 4 representing sludge om the inlet and outlet ends respectively of the Septic nk at Shotley by ether extraction and oxidation by acid rmanganate gives the following results, calculated on e loss on ignition :—

	Ether extract.	Oxygen absorption.
	%	mgrms. per grm.
mple 3	9·0	11·5
mple 4	21·9	14·8

This leads to the rather surprising conclusion that com- to destruction of fat does not take place under anaerobic nditions, though hydrolysis and some breaking down to er fatty acids doubtless does occur. The common perience of the extremely offensive character of old posits of sewage grease buried out of contact with air nfirm this conclusion.

The following tables from page 492 of the Massachusetts port above referred to shows that an appreciable per- ntage of fat is still present in the samples analysed :—

Percentage composition of dry septic tank sludge.

nk.	Date.	Mineral matter	Total organic.	Organic N.	Fats.	Carbon.	Hydrogen.
	Mar., 1906	54·6	45·4	2·7	11·9	25·1	3·0
	Dec., 1901	45·6	54·4	2·6	—	—	—
	Oct., 1903	70·9	29·1	1·1	8·8	—	—
	Nov. 1907	60·1	39·9	2·1	—	—	—
	Dec., 1906	50·7	49·3	2·9	11·8	29·8	4·0
	Dec., 1906	51·0	49·0	2·8	10·8	27·7	3·8

The results in Table V. show that the organic content and ratios of C to H and C to N in the corresponding columns in Tables I., II., IV. and V. are of the same order, and taken in conjunction with the analyses in Table III., point to the conclusion that sludges obtained under aerobic and anaerobic conditions, after incipient decomposition, are similar in empirical chemical composition, though they may differ widely in their physical and biological characters. The "weathered" portions of the samples, bring out the further chemical change under aerobic conditions.

The higher carbon to nitrogen ratios indicate the nitrification of a portion of the nitrogen by bacterial agency, and the subsequent removal of the nitrate, so leaving a residue richer in carbon.

Examination of samples 5 and 7 by ether extraction and oxygen absorption shows disappearance of fatty matter on "weathering," and a simultaneous reduction in oxygen absorption.

	Ether Extract. %	Oxygen Absorption. Mgms. per grm.
Sample No. 5	19·4	15·5
Sample No. 7	13·9	9·6

Analyses of various "slurries" from primary and secondary contact beds, following (except for Nos. 30 and 33) open septic tanks, are given in Table VI.

A study of these figures shows that the ratio of carbon to nitrogen is highest where oxidation is most active, *i.e.*, that the nitrogen is eliminated as nitrate faster than the cellulose, etc., is destroyed under aerobic conditions.

Analyses of slurries from secondary contact beds bring out certain interesting results. It will be noted that

TABLE VI.

Samples from various filter beds, collected under different conditions.

* The lower C : N ratio may in this case be due to elimination of fat on oxidation.

samples from the surface show C : H and C : N ratios lower than those characteristic of primary bed slurry. This would seem to be due to the great amount of bacterial and other life present in the upper portion of the secondary bed. Lower down in the bed or after weathering the carbon increases in proportion to the hydrogen and nitrogen owing to processes of oxidation.

The same result is shown in the analyses of various samples before and after weathering, given in Table VII.

The disappearance of oxidisable matter is further shown by the following results of special examination of a slu before and after 15 days weathering :—

No.	Ether extract (% organic matter)	Oxygen absorption fr permanganate in gru per grm.
27	6·3	69·4
28	7·4	49·7

The following tables quoted from page 331 of the ab mentioned Massachusetts Report indicates the disappe-ance of fat from the deposits from sewage filters :—

Table showing relation between fats and organic matter in sewage sludge, sediment from contact and trickling filters, and sands from experimental sewage filters at Lawrence.

Sample of	Per cent. of Carbon.	Per cent. of Hydrogen.	Per cent. of Fats.	Loss on ignition.	% which fats are of loss on ignition.	% which fats are of carbon.	% carbon in fats.	% carb in fa is of t carb
Andover sludge	27·00	4·0	19·70	49·60	39·3	73·0	12·2	45·
Regular Lawrence Sewage Sludge	38·90	5·3	22·20	69·50	32·2	57·1	13·8	35·5

Sand of Filter No. 9A, Average	0·300		0·017	0·604	2·81	5·67		
Fats in Sewage Sludge	62·0	11·7						

In the following table, from page 376 of the same Report, wo lines have been added giving the percentages of itrogen on the loss of ignition. It is then seen that there s little difference in ratio, confirming the fact stated on age 817 of the present paper, that the empirical chemical omposition of the organic portion of sludges from various ources differs but little.

It is only when these are completely fermented under naerobic conditions or allowed thoroughly to oxidise, are "weathered" so to speak, that a marked change in the hemical ratios becomes apparent. In the first case then hange is mainly due to cellulose fermentation, in the econd case it is the nitrogen which disappears most apidly, though fat destruction takes place. These facts re important from the point of view of agriculture.

nalyses of Sediments from Sewage and Effluents of Filters Nos. 135 *and* 136.

	Sewage sediment.	Sediment of filter.	
		No. 135	No. 136
er cent. of total Nitrogen (Kjeldahl)	2·37	1·37	1·41
er cent. of N detd as Alb. NH_3 ..	1·30	0·70	0·78
er cent. that Albd. NH_3 is of total N (Kjeldahl)	55·00	51·00	55·30
lbuminoid NH_3 (pts. per 100,000)	1575·00	851·00	952·00
oss on ignition (per cent.)	58·50	27·60	31·50
otal Nitrogen (per cent. of loss on ignition)	4·0	4·9	4·4
lbuminoid Nitrogen (per cent. of loss on ignition)	2·2	2·5	2·4

The following general conclusions from the above data pear therefore to be justified :—

1. That there is no great difference in empirical chemical mposition between sludges obtained by ordinary dimentation, incipient septic action, and aerobic sedientation as in slate beds.

2. That under conditions of vigorous anaerobic fermentaon the main change is a destruction of cellulose matter ith a corresponding decrease in the amount of carbon esent compared to the nitrogen and hydrogen.

3. That for the final elimination of fat and of nitrogen, nditions of active oxidation are necessary.

4. Future research may more profitably be directed to e physical and biological differences between sludges of rious origin and the action of special solvents and agents upon them, rather than to their empirical chemical mposition.

The authors' thanks are due to Mr. E. M. Mumford, Sc., and to Mr. J. M. Drummond, M.Sc., for assistance completing the above analyses.

Communication.

ALCOHOL ESTIMATION IN THE TROPICS.

BY E. C. BROWNING, M.A., AND C. T. SYMONS, B.A.

For the last nine years one of the authors has noticed at the usual hydrometer method (*i.e.*, by brass Sikes's drometer) of ascertaining the strength of aqueous oholic solutions at high temperatures (80°—90° F.) gave ults not in agreement with those obtained by pyknoeter readings at 60° F. and Hehner's tables (Analyst., lume 5, 1880, pp. 42—63).

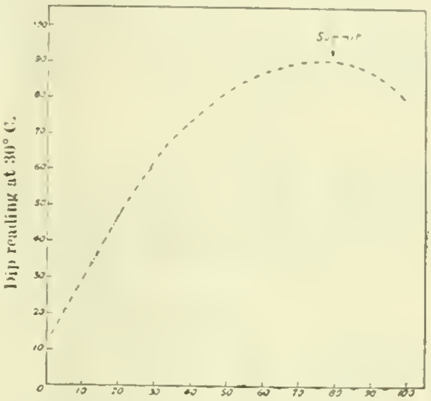
Sir Charles Bedford found that in India, Sikes's tables ve incorrect spirit strengths, especially at high air mperatures and with weak spirits. He has published set of tables for use with Sikes's glass hydrometers, which have been adopted in India. (Corrected Sikes's tables published by the Superintendent, Government Printing, Calcutta, 1910.)

The authors, for the past two years, have been engaged in comparing the readings of glass and brass hydrometers using alcohols whose strength was determined by pyknometer readings at 60° F. and Hehner's tables.

They have also included a set of readings on alcohols whose strength was determined by pyknometer readings at 35° C.* using the standard tables published in 1913 by the United States Bureau of Standards.

At the same time the refractive indices of these alcohols were determined at 30° C. (using the Zeiss immersion refractometer).

This is a very convenient method of rapidly estimating alcohol strengths from 0—35% by weight of alcohol: above this strength the accuracy is not satisfactory, as will be seen from the curve annexed.



% alcohol by wt. (U.S. tables).

Methods.

Various forms of pyknometer were tried, Sprengel's, Perkin's, Bousfield's (Chem. Soc. Trans., 1908, 679—681) using inside and outside cap stoppers, Warren's pattern (100 c.c. capacity with perforated stopper and ground on external cap), and Wade and Merriman's (Chem. Soc. Trans., 1912, 2429—2443). Wade and Merriman's form was found to be by far the most satisfactory. The pyknometers were made either of "R" or quartz glass. The thermostat used for 60° F. consisted of a teak tank holding about 62 litres. It was efficiently lagged and strongly stirred by a series of paddles mounted on a shaft running along the lower portion. A small electric motor with a worm reduction gear supplied the power. Two pieces of plate glass were inserted on the upper portion of two opposite sides so that observations could be made on the level of liquid in the pyknometers while they were immersed in the water. The tank was cooled by circulating ice water through copper coils, the flow of water being controlled by an electrically worked relay.

Temperatures were taken on thermometers recently standardised at the National Physical Laboratory and the Reichsanstalt, a large Beckmann thermometer being used to show variations in temperature. It was not found possible to keep the temperature constant to more than 1/100° C. The thermostat for measurements at 35° C. consisted of a copper tank holding about 89 litres of water. It was mounted in a table and stirred by paddles on a horizontal shaft, driven by a brass chain from a small electric motor with worm reduction gear.

At the top of the two opposite sides, plate glass windows were inserted, like those on the low temperature thermostat. The heating was done by a gas jet controlled by a Lowry spiral regulator.

---

* The temperature of 35° C. was adopted, as the laboratory temperature in the tropics frequently exceeds 30° C., and experiments showed that at 35° C. a very constant temperature could be maintained.

A very sensitive gas pressure regulator controlled the gas supply, and, as the room in which the thermostat was placed had a very steady temperature, it was found possible to keep the thermostat temperature steady within ± 1/1000° C. Wade and Merriman (Chem. Soc. Trans., 1912, 2432) have pointed out that it is necessary to keep the temperature constant within 1/1000° C. to give results accurate to one in the 6th place of decimals and within 1/100° C. to the 5th decimal place, cf. also "Density and thermal expansion of ethyl alcohol and of its mixtures with water," by Osborne, McKelvy, and Bearce (Bull. Bureau of Standards, **9**, **415**).

The hydrometers used were restandardised at the National Physical Laboratory at the conclusion of the series of measurements and the corrections (where necessary) are included in the tables.* All weights used were standardised at the National Physical Laboratory.

The following table gives results obtained with aqueous alcoholic solutions, the strength of which were determined at 60° F. in 100 c.c. pyknometers using Hehner's tables for the calculations.

The hydrometer readings were taken at temperatures about 84°—88° F. (the usual laboratory temperature in the Tropics).

* *i.e.* Tables supplied with the instruments (*e.g.*, Oertling's). These are identical with those supplied by Dring and Fage for use with Sikes' brass hydrometer.

It will be seen that the brass hydrometer with the usual tables (those supplied by the makers of the instrument) gives quite inaccurate results, especially at low strengths and that at no strength are they even approximately satisfactory.

It will also be seen that Bedford's tables used with glass hydrometers give the more satisfactory readings, except at low strengths.

The following table gives results obtained with aqueous alcoholic solutions, the strengths of which were ascertained by pyknometer readings at 35° C. using the United States tables. The hydrometer readings were taken at temperatures from 84°—88° F.

The table requires little comment; the brass hydrometer with the ordinary tables is almost useless, but with Bedford's tables gives very fair results indeed.

There seems no doubt that the new United States tables are among the most accurate that have been published and the authors consider that it would be advisable to base all alcoholic work on these.

The authors also consider that, in view of the confusion caused by the use of the term "proof spirit" it is time that this was dropped, and alcohol strengths given in % of alcohol by weight or by volume.

Hydrometers should be graduated to give % of alcoh by weight or % of alcohol by volume and not % of pro spirit, and for tropical use should be standardised at sa 30° C. and not 51° F.

The following table gives the refractive index of aqueo alcoholic solutions at 30° C. the strength of the alcoh being ascertained from the United States tables.

TABLE C.

Refractive Indices by Zeiss Immersion Refractometer 30° C. Strength of alcohols determined by United St tables (at 35° C.).

Alcohol, % by weight, (United States Tables).	Dip reading at 30° C.	Alcohol. % by weight (United States Tables).	Dip readin at 30° C.
0·	11·8	32·67	65·45
1·02	13·4	34·95	68·30

22·03	50·0	89·28	87·65
25·09	54·85	99·46	80·0
29·15	60·8		

From this table it will be seen that the refractive in x reaches a maximum at about 79·25% by weight of alc ol (cf. Holmes, Chem. Soc. Trans., 1913, 2165). A c e constructed from these figures with refractometer read gs as ordinates and % of alcohol by weight as absc e shows certain irregularities, one being marked at a 5% by weight of alcohol. The measurements have repeatedly and independently checked without producing any change in the curve and it is proposed to investigate these slight irregularities.

---

* The standardisation was done by comparing the hydrometers against the standards at the N. P. L. at 51° F.

The following table is constructed from Table C :—

Table D.

% by weight, Alcohol (U.S.A. Tables).	Dip reading at 30° C.	% by weight Alcohol.	Dip reading at 30° C.
1	13·4	27	57·7
2	15·1	28	59·1
3	16·7	29	60 6

24	53·1	50	81·3
25	54·7	51	82·0
26	56·2		

In conclusion the authors propose to continue the investigations of the refractive index of aqueous alcoholic solutions at varying temperatures, as several points of interest have arisen in the present work which appear to merit close study.

Government Analyst's Laboratory,
Colombo, Ceylon.

Note.—It is worth noting that the glass hydrometers alter as they age, in a somewhat large and irregular manner. For example: A 5-stem set standardised at the N.P.L. against their standards at 60° F. had in 1911 the following corrections :—

Hydrometer No.	0	10	20	30	40	50	60	70	80	90	100
11728	0·0	0·0	0·0								
11729			0·0	0·0	0·0						
11730					−0·1	−0·1	−0·1				
11731							−0·1	0·0	−0·1		
11732									−0·2	−0·2	0·0
In 1914 the same set at 60° F. gave											
11728	−0·3	−0·2	−0·2								
11729			−0·2	−0·3	−0·3						
11730					−0·2	−0·2	−0·2				
11731							−0·1	−0·1	−0·2		
11732									−0·3	−0·4	−0·1

Journal and Patent Literature.

Patent Specifications may be obtained by post by remitting as follows :—
English.—8d. each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane, London, W.C.
United States.—1s. each, to the Secretary of the Society.
French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.); Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.
German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, German.

I.—GENERAL PLANT; MACHINERY.

Patents.

Furnaces. W. Cross, London. From La Soc. des Perfectionnements à la Vaporisation, Paris. Eng. Pat. 14,432, June 21, 1913.

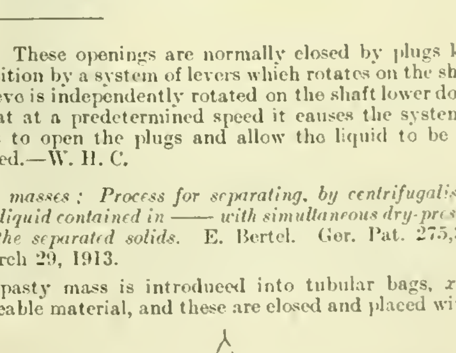
Three inclined reciprocating grates are arranged with the two uppermost inclined from front to rear step fashion, and the third inclined in the opposite direction below the second. The fuel is fed on to the top of the upper grate from a rotating drum hopper and the ashes are similarly discharged from the bottom of the lowest grate. All the grates have closed ash-pits into which air is delivered under pressure; the front of the furnace is also closed.—W. H. C.

Separating machines; Centrifugal ——. B. Hoffman. Topeka, Kans. U.S. Pats. 1,101,548 and 1,101,549, June 30, 1914; dates of appl., Oct. 21 and 24, 1911.

(1). A closed drum is mounted on a hollow horizontal shaft and rotated in a vertical plane. The liquid is fed into one end of the shaft and is delivered to the inner periphery of the drum through radial branch pipes which project from the hollow shaft and have their ends turned in a direction opposite to that in which the drum rotates. The heavier liquid collects at the inner periphery of the drum, is collected by radial pipes extending from the hollow shaft and is discharged from the opposite end to that by which the liquid enters, the shaft having a partition in the centre. The lighter liquid passes directly into another passage in the hollow shaft from the axis of the drum. (2). The drum of the machine has the form of a frustum of a cone and is rotated on a vertical shaft. The liquids to be separated are fed into the drum near the axis and the separated liquids are discharged the one over the upper edge of the drum and the other through one or more openings formed in the periphery of the drum at its widest part. These openings are normally closed by plugs kept in position by a system of levers which rotates on the shaft. A sleeve is independently rotated on the shaft lower down, so that at a predetermined speed it causes the system of levers to open the plugs and allow the liquid to be discharged.—W. H. C.

Pasty masses; Process for separating, by centrifugalising, the liquid contained in —— *with simultaneous dry-pressing of the separated solids.* E. Bertel. Ger. Pat. 275,387, March 29, 1913.

The pasty mass is introduced into tubular bags, *x*, of permeable material, and these are closed and placed within the basket of a centrifugal machine as shown in the figure. The liquid separated from the mass passes out through the



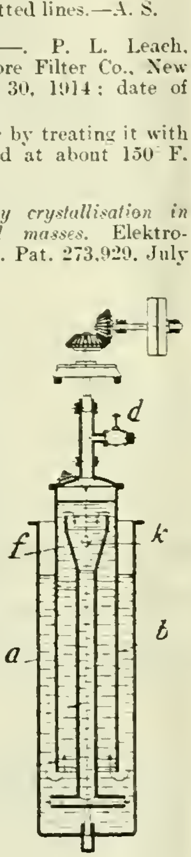
basket and the residue is compressed by the action of centrifugal force aided by the movable members. 14, which may be hollow metal boxes weighted by filling with water. Around the pressing members, 14, is a casing, 17, which is kept in place after the fashion of a spring, and serves to shut off the space containing the bags, *x*, from the interior of the centrifuge. Channels, 9 and 10, are provided so that the bags, *x*, may be compressed into the form of flat plates as shown by the dotted lines.—A. S.

Filter-leaves; Method of cleaning ——. P. L. Leach, Wollaston, Mass., Assignor to Moore Filter Co., New York. U.S. Pat. 1,101,639, June 30, 1914; date of appl., Oct. 25, 1911.

LIME is removed from the filter fabric by treating it with a 4% aqueous solution of lactic acid at about 150° F. (66° C.).—W. H. C.

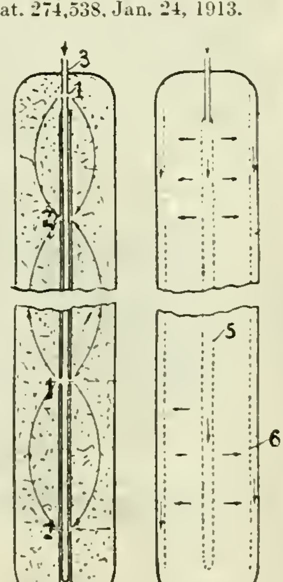
Crystals; Production of large —— *by crystallisation in motion from solutions and fused masses.* Elektrochemische Werke G. m. b. H. Ger. Pat. 273,929, July 17, 1913.

IN the apparatus shown in the figure, *a* is the dissolving vessel, or receptacle for the fused mass, and *f* is the crystallising vessel, which is fixed to, and rotates with, the tube, *b*. Suction is applied at *d* to draw the liquid up to the level of the upper edge of *f*, then the cock, *d*, is closed and the tube, *b*, is rotated, whereby circulation of the liquid is set up as shown by the arrows. A crystal to act as a nucleus is suspended at *k*. By raising or lowering *b*, the difference of level between the liquid in *a*, which may be heated, and in *f*, and hence also the difference in temperature, can be regulated as desired.—A. S.



Gas reactions; Process for carrying out high-pressure ——. K. H. Vallalat. Ger. Pat. 274,538, Jan. 24, 1913.

THE gaseous mixture instead of passing through the entire length of the reaction chamber, is divided into a number of separate currents, each of which travels only a fraction of the total length. In the form of apparatus shown in Fig. 1, the gas is forced into the reaction chamber through openings, 1, in the inner tube, 3, and is drawn into the outer outlet tube, 4, through openings, 2. In the modification shown in Fig. 2, the gas is forced through the permeable tube, 5, into the reaction chamber, and is withdrawn from the annular space formed between the outer wall and the permeable partition, 6.—A. S.



Reaction-vessel for carrying out chemical processes of all kinds between two or more liquids, solutions, solids in paste form, and also gases. Westfälisch-Anhaltische Sprengstoff-A.-G. Ger. Pat. 274,854, Sept. 27, 1912.

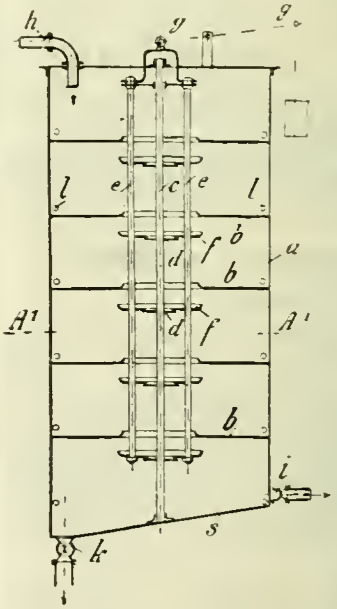
THE apparatus consists essentially of two vessels, one within the other, and either or both of which may be rotated. The outer vessel has blades, projecting from its inner surface and the inner vessel has, on its outer surface, similar blades projecting into the spaces between the blades on the outer vessel. The materials pass continuously through the space between the two vessels. The apparatus is specially suitable for the manufacture of explosive substances, *e.g.*, for the nitration of toluene. —A. S.

Oxidation-reactions; Process for carrying out ——. Badische Anilin und Soda Fabrik. Ger. Pat. 275,518, March 30, 1913.

RUTHENIUM or one of its compounds is used as an oxidation catalyst. The application of these catalysts to the oxidation of gaseous hydrocarbons by means of air is disclaimed.—T. F. B.

Clarifying apparatus for intermittent or continuous working. H. Pappé. Ger. Pat. 274,869, June 22, 1913.

THE apparatus consists of an upright vessel, *a*, preferably with a sloping bottom, *s*, and divided into compartments by partitions, *b*, *b*, the centres of which have circular openings with raised edges. Below these openings a number of circular trays, *f*, *f*, with central openings, are supported on discs, *d*, *d*, fixed to a vertical shaft: these trays are slightly larger than the openings in the plates, *b*, *b*. The liquid to be clarified is run in through *h*, and, passing down the apparatus, deposits the solid particles on the trays and plates, finally running off through *i*. To clean the apparatus, the trays, *f*, *f*, together with the framework, *e*, *e*, are lifted by means of the counterpoise, *g*, so that they close the openings in the plates, *b*, *b*; water or other washing liquid is then pumped in through openings as shown at *l*, *l*, washing the solid from the trays and plates, through the central openings in the trays, *f*, *f*, into the bottom o the vessel, whence it is run off through *k*.—T. F. B.



Dialyser-membranes. R. Hömberg, C. Brahm, and H Mühsam. Ger. Pat. 274,963, Sept. 19, 1913.

THE membranes are prepared from solutions of "konny aku" (a product obtained from *Conophallus*, *Colocasia* and similar kinds of plants). The membranes may be mad more elastic by adding softening agents, such as oils, t the solutions, and they are rendered insoluble in water b treatment with alkalis or other alkaline substance alkaline-earth carbonates, or basic salts. To increase th strength of the membrane, inert substances such as bariu sulphate, talc, kieselguhr and the like may be incorporate with the solution or may be precipitated in the membrar during its fixing or after-treatment.—A. S.

Drying aqueous animal or vegetable liquids, etc., by admixture of anhydrous sodium sulphate. V. Niegovan. Ger. Pat. 275,127, June 7, 1913. Under Int. Conv., June 7, 1912.

After mixing with anhydrous sodium sulphate, the mass is dried by exposure to a temperature below the melting point of Glauber's salt, *e.g.*, in a vacuum over sulphuric acid. When the sodium sulphate is again completely dehydrated, the mass falls to a fine powder from which the anhydrous sodium sulphate can be separated by means of its insolubility in anhydrous organic solvents.—A. S.

Drying apparatus. J. E. Hobbs, Coulsden, Assignor to Ransome-ver Mehr Machinery Co., Ltd., London. U.S. Pat. 1,102,662, July 7, 1914. Date of appl., Oct. 21, 1912.

See Eng. Pat. 29,313 of 1911; this J., 1913, 221.—T. F. B.

Drying or cooling granular materials; Process of ——. E. Bornmann, Assignor to J. A. Topf und Söhne, Erfurt, Germany. U.S. Pat. 1,102,714, July 7, 1914. Date of appl., Oct. 29, 1913.

See Eng. Pat. 29,835 of 1912; this J., 1913. 1147.—T. F. B.

Liquids; Apparatus for aerating and gasifying ——. T. K. Irwin. Fr. Pat. 467,288, June 14, 1914. Under Int. Conv., Jan. 23, 1913.

See Eng. Pat. 1925 of 1913; this J., 1914, 274.—T. F. B.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Hydrogen and methane; Modification of the Jaeger method for determining ——. Wibaut. J. Gas Lighting, 1914, 127, 174.

The Jaeger method consists in the fractional combustion of the gaseous mixture by passing it over copper oxide, first at 250°—270° C., to burn the hydrogen, and then at red heat to burn the methane. Both steps in the process are very slow. To accelerate the combustion, the author adds sufficient cerium dioxide to give a grayish white mixture with the copper oxide. A silica combustion tube is used, filled with nitrogen before the experiment, and the gas is passed through the tube 4 to 6 times, each passage taking 1 to 2 mins. The copper oxide is regenerated by means of oxygen after each experiment. A sample of coal gas containing H 49·9% as determined by absorption with palladium black, and CH_4 20·9% as determined by explosion, gave by the new method, H 49·5 and CH_4, 21·2%.—A. T. L.

Mineral oil exports from the United States. Oil, Paint, and Drug Rep., Aug. 3, 1914. [T.R.]

Exports of mineral oils from the principal customs districts of the United States (representing about 98% of the shipments from all parts), during the twelve months, July 1, 1913, to June 30, 1914, were as follows:—

	Gallons.	Value Dollars.
Crude oil	146,056,086	6,808,513
Illuminating oil	1,155,809,430	74,374,091
Lubricating and paraffin oils	195,472,181	27,566,378
Naphthas, gasoline, etc.	185,578,776	26,568,682
Residuum, gas oil, fuel oil, etc.	586,301,600	15,562,192
Total, 1913-14	2,269,218,073	150,879,856
Total, 1912-13	1,947,746,303	134,514,109

Patents.

Peat sods, which may be immediately stacked, made from partly drained peat. J. W. R. von Traubenberg, Reval, Russia. Eng. Pat. 15,715, July 8, 1913.

A mixture of young or fibrous peat cut from the upper layers of the bog, with an equal or greater quantity of amorphous peat from the lower layers, is pressed and cut into sods, which may be stacked for air-drying. These may contain up to 91% moisture, although amorphous peat alone, containing 88% moisture, cannot be stacked —A. T. L.

Coke ovens, etc.; Apparatus for charging ——. J. J. Allen, Crook, Durham. Eng. Pat. 1121, Jan. 15, 1914.

The charging device, which is brought opposite the mouthpiece of a horizontal retort, has a stiff centre bar carrying pivoted push-plates which are held against stops in an operative position during the forward movement of the bar, and are free to move about their pivots so as to be drawn over the coal on the return stroke. The stops are arranged so that the push-plates are slightly inclined to the vertical on the charging stroke, and to the horizontal on the return stroke, whereby the coal is pressed downwards on both strokes of the bar.—A. T. L.

Coke; Process for cooling hot —— by means of inert waste gases. W. Walch. Ger. Pat. 275,436, Nov. 4, 1913.

Waste gases from the heating of the coke ovens are passed through a heat-interchanger (*e.g.*, a steam boiler or the like) and are then used to cool the hot coke, after which they are again passed through the heat-interchanger. —A. S.

Coal; Continuous carbonisation of —— in vertical retorts. H. J. Toogood and R. Dempster and Sons, Ltd., Elland, Yorks. Eng. Pat. 9400, April 22, 1913.

The cooling chambers, or coke receptacles, at or near the bottom of each retort are connected by valve-controlled by-pass pipes, so that any temporary excessive gas pressure in one retort may be relieved by opening the valve. Automatic dip seals may be used instead of the valves. In a retort of elongated cross-section, the coal-feeding shoot is situated centrally of the major cross-sectional axis in such a manner that the outer edges of the top of the charge are within the heated portion of the retort.—W. F. F.

Distillation of coal; Treatment of hot gases produced by ——. W. J. B. Leech and A. Edwards, Leeds. Eng. Pat. 20,964, Sept. 17, 1913.

The gas from the retort is cooled, and deposits of pitch and ammonium chloride prevented, by the introduction of regulated sprays of circulating water and coal tar, applied respectively between the hydraulic main and the retort mouthpiece, and against the gas stream at a point behind the hydraulic main. The ammonium chloride solution and the tar flow together into a circulating well, the circulation continuing until the solution is strong enough to allow of crystallisation of ammonium chloride. —W. F. F.

Gas producers; Suction ——. H. Dormand, Hartlepool. Eng. Pat. 27,201, Nov. 26, 1913.

To avoid the pulsation of the fuel in the feed-pipe at every suction stroke of the engine, a vacuum is maintained in an annular enlargement in the feed-pipe. Side feed apertures are formed at the delivery end of the pipe. The zone of combustion in the producer is regulated by the provision of a circular vaporiser around the combustion chamber, the water supply being adjustable, and the mixed air and water vapour being delivered into the sealed ash-pit. —W. F. F.

Gas producers. J. A. Herrick, New York. U.S. Pats. 1,100,074 and 1,100,075, June 16, 1914; date of appl., Feb. 27, 1911. Renewed, Nov. 12, 1913.

(1) A gas producer is formed with fixed upper and lower sections carrying a number of stirrers projecting into the middle section, which is rotatable. (2) The producer is entirely stationary, but the stirrers projecting from the upper and lower ends are caused to rotate. The air is introduced through a number of radial tuyère boxes, upon which the lower stirrers are mounted.—H. H.

Illuminating gas; Device for indicating naphthalene in ——. E. St. Claire Deville, Assignor to Soc. du Gaz de Paris, Paris. U.S. Pat. 1,100,231, June 16, 1914; date of appl., Apr. 24, 1913.

The gas is cooled and passed through a restricted orifice, the fall in temperature and the pressure difference on each side of the orifice being noted. The saturation temperature of the gas with naphthalene vapour may also be determined by the apparatus if the gas be first passed through a receptacle containing naphthalene.—H. H.

Gas generator. D. D. Barnum. Worcester, Mass. U.S. Pat. 1,100,941, June 23, 1914; date of appl., Mar. 1, 1912.

A steam injector is fitted near the centre of the grate of a gas producer to force an upward jet of steam through the central mass of fuel, while radial jets arranged just above the grate introduce steam under pressure at the sides of the producer.—H. H.

Combustible elastic fluid mixtures; Means for regulating ——. A. C. Ionides, London. Eng. Pat. 15,758, July 8, 1913.

A sensitive bell or diaphragm, subjected on its two sides to the static pressures of the two constituents of the mixture (*e.g.*, gas and air) is connected by lever arms to two regulating valves, each of double-beat type, in such a way that the weight of the bell or diaphragm is counterbalanced. The constituents are admitted to the mixing chamber through flap valves, the loads on which are independently adjustable. A slide-valve allows the strength of the mixture to be varied without altering the ratio of the pressures at the double beat valves. —W. F. F.

Gas producers; Apparatus for regulating the air supply for ——. H. L. Doherty, New York. U.S. Pat. 1,101,787, June 30, 1914; date of appl., Feb. 15, 1910.

A valve in the air-supply conduit is moved in one direction by hand and is returned slowly by a weight, the return movement being controlled by a liquid dash-pot having an adjustable by-pass valve.—A. T. L.

Gas; Apparatus for purifying ——. H. F. Smith, Lexington, Ohio. U.S. Pat. 1,099,773, June 9, 1914; date of appl., Oct. 12, 1912.

The gas is passed through a rotatable cage containing a pervious diaphragm to separate tar particles. Upon rotation of the cage, the gas passes through the diaphragm in the reverse direction.—H. H.

Fuels for internal-combustion engines, and means for preparing them for use. L. N. Reddie, London. From Explosions-Turbine-Studienges. m. b. H., Berlin-Wilmersdorf, Germany. Eng. Pat. 14,520, June 23, 1913.

Fuel which can be used in a carburettor without heating, consists of an emulsion made by stirring together crude oil or tar, a light oil such as crude naphtha or benzene, and a liquid which does not mix with the oils, such as water or alcohol. To render the emulsion permanent, soap, caustic soda, ammonia, sodium carbonate, lime water, milk, or rubber solution may be added. Examples given are: (1) crude naphtha, 500; water, 50; soft soap, 10; and petroleum, 100 parts; (2) gas tar, 100; benzene, 100; soap and water, 10; alcohol, 10; and petroleum, 10 parts; (3) crude naphtha, 500; crude petroleum, 200—300; water, 50—100; and soap, 5—10 parts. —A. T. L.

[Mineral] Oils; Treating [diminishing the viscosity of] ——. A. Philip, Portsmouth. Eng. Pat. 14,778, June 26, 1913.

Petroleum oils, which are too viscous to be readily pumped or otherwise handled, may be rendered less viscous by addition of naphthalene up to about 8% by weight of the mixture. Oils of which the high viscosity is due to the presence of the heavier paraffins may be treated in this way.—W. F. F.

Hydrocarbons [pentanes]; Process of obtaining liquid ——. E. Schill, Assignor to Continental Gas Compressing Corporation, New York. U.S. Pat. 1,100,260, June 16, 1914; date of appl., Oct. 10, 1912.

A gaseous mixture of hydrocarbons of low, medium and high boiling points is compressed in the presence of a finely divided heat-absorbing agent and cooled sufficiently to liquefy the portions, normally volatilised above 25° C., having the medium and high boiling points. The liquefied mixture is led whilst still under pressure, to a still where the ingredients of medium boiling point, viz. the pentanes, are distilled off.—H. H.

Oil; Treating [dehydrogenating] ——. J. A. Dubbs, Pittsburgh, Pa., Assignor to R. J. Dunham, Chicago, Ill. U.S. Pat. 1,100,717, June 23, 1914; date of appl., Nov. 9, 1905.

Hydrocarbons are dehydrogenated by heating to a temperature at which they are broken up when mingled with air, and forcing air through at a rate sufficient to maintain continuous distillation without further application of heat. —H. H.

Oils; Apparatus for fractionating mineral ——. C. B. Forward, Urbana, Ohio. U.S. Pat. 1,100,966, June 23, 1914; date of appl., Mar. 4, 1914.

A retort for heating oils under pressure at about 650° F. (343° C.) is provided with a series of condenser columns, the first of which has pipe connections so that the liquid condensed therein can be returned direct to the retort in order to control the quality of the asphaltum base left in the retort.—H. H.

Petroleum hydrocarbons; Treatment of ——. R. F. Bacon and C. W. Clark, Pittsburgh, Pa. U.S. Pat. 1,101,482, June 23, 1914; date of appl., May 6, 1912.

Petroleum hydrocarbons having a boiling point of about 250° C. and upwards are decomposed and distilled under a pressure of 100 to 300 lb. per sq. in., the heat being applied at such a rate as to give a minimum yield of 18% of gasoline hydrocarbons boiling at 30° to 150° C.—H. H.

Combustion; Method of conducting ——. *Methods of burning liquid fuels.* H. L. Doherty, New York. U.S. Pats. 1,101,788, 1,101,789, and 1,101,790, June 30, 1914. Dates of appl., Jan. 10, Jan. 10, and April 13, 1911.

(1). In a kiln for calcining carbonate minerals by direc contact with the flame, liquid fuel is sprayed by a stean jet and admitted to the combustion chamber with limited quantity of air so as to effect a partial combustio of the fuel in contact with refractory material and t convert the unburnt fuel into fixed gases; and the resultin gaseous products are mixed with air containing at leas 30% of combustion products and brought into contac with the hot materials in the kiln, whereby complet combustion is effected, and a large flame of moderat temperature is formed. (2). For decomposing material by direct contact with flame, the process described abov is modified by using compressed air in place of stean (3). Liquid fuel is atomised, mixed with carbon dioxid and air, and partially burnt, and the resulting gas is burn with a further supply of air. The quantity of carbo dioxide is such as to prevent the production of soot durin the initial combustion, and the quantity of primary air sufficient to give a temperature between 1300° and 2000° (704°—1093° C.).—A. T. L.

Burning finely-divided fuel; Apparatus for ——. D. Irish, New York, Assignor to The Babcock and Wilc Co., Bayonne, N.J. U.S. Pat. 1,102,510, July 7, 191 Date of appl., April 1. 1913.

See Eng. Pat. 18,712 of 1911; this J., 1912, 864.—T. F.

Fuels; Method and device for measuring the heating val of ——. H. Junkers, Aix-la-Chapelle, Germany. U Pat. 1,103,915, July 14, 1914. Date of appl., Oct. 1913.

See Eng. Pat. 22,514 of 1913; this J., 1914, 105.—T. F.

Heating peat and other peaty substances; Process and apparatus for ——, to prepare them for mechanical dehydration. G. Wolters. Fr. Pat. 467,344, March 27, 1913.

See Eng. Pat. 2766 of 1913; this J., 1913, 1000.—T. F. B.

Briquettes of coal and carbonaceous waste; Process for making ——. Naamlooze Vennootschap Briquet Co. (Briket Maatsch.). Fr. Pat. 467,572, Jan. 22, 1914. Under Int. Conv., Feb. 1, 1913.

See Eng. Pat. 5416 of 1913; this J., 1913, 860.—T. F. B.

Coke ovens; Regenerative ——. E. Lecocq, Brussels. Eng. Pat. 16,599, July 19, 1913. Under Int. Conv., Sept. 4, 1912.

See Fr. Pat. 460,399 of 1913; this J., 1914, 67.—T. F. B.

Coal, shale or the like; Process and apparatus for the treatment of —— in vertical retorts. A. Waddell, Dunfermline. U.S. Pat. 1,103,112, July 14, 1914. Date of appl., Sept. 11, 1913.

See Eng. Pat. 21,991 of 1912; this J., 1913, 690.—T. F. B.

Water-gas; Process for the production of ——. Dellwik-Fleischer Wassergas-Ges. m. b. H., Frankfort, Germany. Eng. Pat. 304, Jan. 5, 1914. Under Int. Conv., Aug. 6, 1913.

See Fr. Pat. 466,421 of 1913; this J., 1914, 585.—T. F. B.

Gas producers; Rotary grate for ——. K. Koller. Fr. Pat. 467,540, Jan. 21, 1914. Under Int. Conv., Jan. 22, 1913.

See Eng. Pat. 1692 of 1914; this J., 1914, 740.—T. F. B.

Gas producer. C. Whitfield. Fr. Pat. 467,676, Jan. 24, 1914.

See Eng. Pat. 1117 of 1913; this J., 1914, 190.—T. F. B.

Gas washer. W. J. Fiddes. Fr. Pat. 466,456, Dec. 22, 1913. Under Int. Conv., June 14, 1913.

See U.S. Pat. 1,095,835 of 1914; this J., 1914, 585.—T. F. B.

Gas liquor; Method of treating —— in small gas works. Berlin-Anhaltische Maschinenbau-Act.-Ges., Berlin. Eng. Pat. 4242, Feb. 18, 1914. Under Int. Conv., May 9, 1913.

See Ger. Pat. 269,658 of 1913; this J., 1914, 685.—T. F. B.

Benzol from petroleum or its distillates; Process for obtaining ——. J. Holegreber, Lodz, Russian Poland. Eng. Pat. 17,272, July 28, 1913.

See Fr. Pat. 460,827 of 1913; this J., 1914, 17.—T. F. B.

Petroleum distillation; Process of treating residue of ——. H. Wade, London. From Standard Oil Co., Whiting, Ind., U.S.A. Eng. Pat. 6593, March 16, 1914.

See U.S. Pat. 1,049,667 of 1913; this J., 1913, 414.—T. F. B.

Manufacture of wagon- and machine-grease. Ger. Pat. 274,209. *See* XII.

Manufacture of lubricants and substances for adding thereto, capable of indicating "hot running." Ger. Pat. 275,055. *See* XII.

Apparatus for testing lubricants. Ger. Pat. 275,225. *See* XXIII.

Device for detecting combustible or explosive gases, especially firedamp. Eng. Pat. 15,064. *See* XXIII.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Lighting and heating flames; Investigations on the quantity of carbon monoxide and nitric oxide in ——. E. Terres. J. Gasbeleucht., 1914, **57**, 605—613, 700—706.

The quantities of carbon monoxide and of nitric oxide were determined in the combustion products from inverted and upright incandescence burners, from a petroleum lamp and from candles, from a heating burner placed beneath a vessel of water, and from the burner of a Junkers' calorimeter. The amount of carbon monoxide was from 0·2 to 0·4, of nitric oxide 0·06 to 0·17 and of sulphur dioxide 0·025 to 0·12% of the amount of carbon dioxide formed. With insufficient primary air, the amount of carbon monoxide was 1·7 to 2% of the amount of carbon dioxide. In an atmosphere contaminated with combustion products that it contains 1% of carbon dioxide, these quantities are well below the danger point. In a room of 48 cb. m. capacity, without special means for ventilation, and lighted by gas, the quantity of carbon dioxide could rarely reach 0·5 or 0·75%.—A. T. L.

Patents.

Wood; Plant for carbonising ——. R. Dittmer. Ger. Pat. 275,516, Feb. 8, 1913.

In a carbonising plant comprising vertical retorts with outlets at their bases, the charge is heated first at the top, so that carbonisation proceeds downwards: in this way the contact of tar and other products with the highly heated retort walls, is avoided.—T. F. B.

Electrodes for arc lamps; Manufacture of ——. F. M. Lewis, Brighton. Eng. Pat. 22,222, Oct. 2, 1913. Under Int. Conv., July 2, 1913.

See Ger. Pat. 271,993 of 1913; this J., 1914, 543.—T. F. B.

III.—TAR AND TAR PRODUCTS.

Dimethylaminodihydroxybenzophenone. M. Wenzing. Ber., 1914, **47**, 2152—2156.

When Michler's ketone is heated with resorcinol and zinc chloride an addition product is first formed (Ger. Pat. 31,321). The author carried this reaction further and obtained dimethylaminodihydroxybenzophenone:

$$[(CH_3)_2N.C_6H_4]_2C(OH).C_6H_3(OH)_2 \rightarrow (CH_3)_2N.C_6H_4.CO.C_6H_3(OH)_2 + C_6H_5.N(CH_3)_2.$$

The new product was isolated as its zinc chloride double salt. The free base exists in two crystalline modifications, needles melting at 165°—167° C., and leaflets melting at 171°—172° C. It is insoluble in water but forms soluble salts. The base is soluble in caustic alkali with an intense yellow colour.—J. B.

Use of refined coal tar in the creosoting industry. Von Schrenk and Kammerer. *See* IX.

Report on wood preservatives [*creosote oil*]. *See* IX.

Quantity and character of creosote in well-preserved timbers. Alleman. *See* IX.

Patents.

Diarylurea chlorides; Manufacture of ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 20,107, Sept. 5, 1913.

Diarylamines can be converted completely into the corresponding diarylurea chlorides, free or practically free from the diarylamine hydrochloride, by carrying out the last part of the treatment with phosgene at a higher temperature (*e.g.*, 100° C.), and continuing the reaction until all the diarylamine hydrochloride has been converted into the urea chloride. The process may be carried out either in absence or in presence of a diluent or solvent.—T. F. B.

Ureas of the naphthalene series; Manufacture of ——. Farbenfabr. vorm. F. Bayer und Co. Eng. Pat. 9472, April 16, 1914. Under Int. Conv., June 21, 1913.

New ureas of the naphthalene series, suitable for medicinal purposes and for the production of substantive cotton dyestuffs, are obtained by treating with phosgene derivatives of 1.8-aminonaphtholsulphonic acids which are substituted in the amino group by the aminobenzoyl or aminobenzoylaminobenzoyl residues or their derivatives, or by a number of similarly grouped aminobenzoyl residues or their derivatives. The compound produced by the action of phosgene on *p*-aminobenzoyl-1-amino-8-naphthol-4 6-disulphonic acid has a strong curative effect on animals affected with trypanosomes, and when combined with diazobenzene yields a pure bluish-red dyestuff.—T. F. B.

Aminoanthraquinones or their derivatives; Manufacture of ——. Act.-Ges. f. Anilinfabr., Treptow, Germany. Eng. Pat. 8917, April 8, 1914. Under Int. Conv., June 30, 1913.

The ureas produced by the action of phosgene on 3-aminobenzoyl-o-benzoic acid or its derivatives, can be condensed to anthraquinone derivatives by heating with concentrated or fuming sulphuric acid. The condensation takes place at 80°—90° C., without saponification occurring; by heating for a longer period or to a higher temperature, the ureas are saponified and the corresponding aminoanthraquinones produced. When ureas of 3-aminobenzoyl-o-benzoic acid having a free 6-position are used, the process yields mainly 2-aminoanthraquinones, with small proportions of 1-aminoanthraquinone derivatives. On the other hand, when compounds substituted in the 6-position, such as 3-amino-6-halogenbenzoyl-*o*-benzoic acids, are used, the products consist exclusively of 1-aminoanthraquinone derivatives.
—T. F. B.

Anthraquinone; Process of making ——. F. Singer and E. Milarch, Offenbach, Assignors to Chem. Fabr. Griesheim-Elektron, Frankfort on Maine, Germany. U.S. Pat. 1,103,383, July 14, 1914. Date of appl., Jan. 8, 1914.

Anthracene is treated with nitric acid in presence of an indifferent liquid, at a temperature below 60° C., and the intermediate product is converted into anthraquinone by treatment with nitric acid above 60° C.—T. F. B.

Anthraquinone nitriles; Process for preparing ——. Farbwerke vorm. Meister, Lucius, und Brüning. Ger. Pat. 275,517, March 23, 1913. Addition to Ger. Pat. 271,790 (see this J., 1914, 637).

β-Halogen-anthraquinones are converted into anthraquinone-β-nitriles by heating them with copper cyanide in presence of an indifferent solvent. The products may be used for preparing dyestuffs.—T. F. B.

Anthracene derivatives; Process for preparing ——. M. Kardos. Ger. Pat. 275,248, May 4, 1913.

Anthracene or one of its derivatives is treated with malonyl chloride in presence of a substance which assists condensation. Coloured compounds are obtained, which are probably 1.9-malonylanthracene derivatives. Mild oxidation (*e.g.*, with permanganate) in alkaline solution converts them into anthraquinone-1-carboxylic acid or its derivatives.—T. F. B.

Dihalogen-carbazoles; Process for preparing nitration products of ——. G. List. Ger. Pat. 275,833, Aug. 14, 1912.

Carbazole is treated with a halogen or its equivalent in glacial acetic acid solution, and when the reaction is complete the product is treated with concentrated nitric acid. The dihalogen-nitrocarbazoles thus produced differ from the known compounds in having at least one labile halogen atom: the reactivity of the halogens can be increased by introducing a sulphonic or other acidic group into the molecule.—T. F. B.

Hydrocarbons; Process for the systematic oxidation of —— *by air at the ordinary temperature.* Soc. Anon. des Combustibles Industriels. Fr. Pat. 467,715, April 3, 1914.

See Eng. Pat. 10,208 of 1913; this J., 1914, 586.—T. F. B.

Sulphonic acids; [Electrolytic] process of producing ——. A. Vagt, Leverküsen, Assignor to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 1,102,827, July 7, 1914. Date of Appl., Dec. 6, 1911.

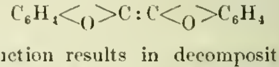
See Fr. Pat. 439,012 of 1912; this J., 1912, 579.—T. F. B.

Obtaining benzol from petroleum or its distillates. Eng. Pat. 17,272. *See* IIa.

IV.—COLOURING MATTERS AND DYES.

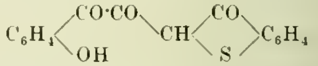
Oxindigo. I. K. Fries, A. Hasselbach, and L. Schröder. Annalen, 1914, **405**, 346—372.

By the method previously described for oxindigo (this J., 1911, 124) 6.6′-dimethyl-2.2′-biscumaronindigo and 5.5′-dichloro-2.2′-biscumaronindigo have been prepared and found to differ little from the parent substance. Reduction of oxindigo by zinc dust and acetic anhydride gives the diacetate of oxindigo white; in glacial acetic acid however reduction goes further and four atoms of hydrogen are taken up, probably with formation of

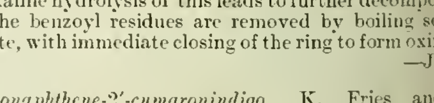


$$C_6H_4<\overset{CH\cdot OH}{\underset{O}{}}>C:C<\overset{CH\cdot OH}{\underset{O}{}}>C_6H_4$$

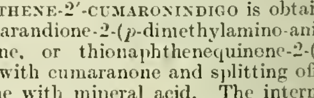
Alkaline reduction results in decomposition. By th action of alkali on the mixed thio-oxindigo only th cumarone ring is affected and the compound,



is formed. It is therefore probable that in the case of oxindig the compound, $HO.C_6H_4.CO.CH(OH).CO.CO.C_6H_4.OH$, first formed, and this is further broken down by the actio of the alkali. Oxindigo is also decomposed by miner acids, o-hydroxybenzoylformic acid and a compoun $C_{16}H_{10}O_4$, resulting. This compound is soluble in alkal and forms an acetyl derivative. By heating it is converte into an isomeride of similar properties. The decompositi by alkalis has been investigated by means of the additi products of primary amines with oxindigo, which a relatively stable against alkalis. The addition product fro *p*-aminodimethylaniline is attacked by alkali on one si of the ring only. The product can be isolated as the benzo compound, which has the formula:



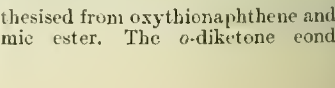
and when treated with mineral acid yields aminodimeth aniline and the compound,



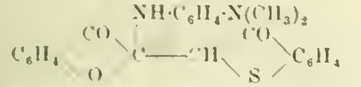
Alkaline hydrolysis of this leads to further decomposit but the benzoyl residues are removed by boiling sodi acetate, with immediate closing of the ring to form oxindi
—J. B

2-*Thionaphthene-2′-cumaronindigo.* K. Fries and Bartholomäus. Annalen, 1914, **405**, 373—394.

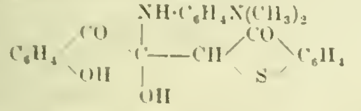
2-Thionaphthene-2′-cumaronindigo is obtained by c densing cumarandione-2-(*p*-dimethylamino-anil) with thionaphthene, or thionaphthenequinone-2-(*p*-dimet amino-anil) with cumaranone and splitting off *p*-amin methylaniline with mineral acid. The intermediate duct is the same, whichever method of formation is u so that direct formation of thio-oxindigo must oc combination with the free amine then taking place. oxindigo the new mixed indigo has no vat-dyeing prope as it is decomposed by alkalis. The decomposition proc



can be synthesised from oxythionaphthene and *o*-hydr benzoylformic ester. The *o*-diketone condenses th o-phenylenediamine to give a quinoxaline derivative and it forms a dibenzoyl derivative with benzoyl chloride. By heating to 180° C. thio-oxindigo is re-formed. The aminodimethylaniline condensation product of thio-oxindigo must have the constitution



since it is decomposed by alkalis to form the product



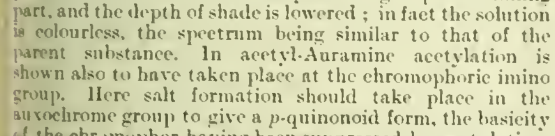
characterised by its dibenzoyl derivative (see preceding abstract).—J. B.

Auramine ; The constitution of ——. E. Grandmougin and S. Favre-Ambrumyan. Ber., 1914, 47, 2127—2132.

To decide between the rival formulæ for Auramine (Graebe's and Stock's) it is necessary to know at which part of the molecule salt formation takes place—in the chromophoric imino group or in the auxochrome dimethylamine group. According to the authors' views a deepening of the shade should take place in the first case, whilst in the second the shade would be raised in the direction of the light end of the spectrum (see this J., 1913, 973 ; 1914, 687). Spectroscopic examination shows that salt formation is, in fact, accompanied by a deepening and a doubling of the chief band to 375 and 435 $\mu\mu$. The case is parallel with that of phenazine (this J., 1914, 687). On the other hand if concentrated acid is used, double salt formation takes place, the auxochrome dimethylamino group also taking part, and the depth of shade is lowered ; in fact the solution is colourless, the spectrum being similar to that of the parent substance. In acetyl-Auramine acetylation is shown also to have taken place at the chromophoric imino group. Here salt formation should take place in the auxochrome group to give a *p*-quinonoid form, the basicity of the chromophor having been suppressed by acetylation. The spectrum of the blue solution thus obtained shows, however, no relationship with the other observations and some further change must be assumed to have taken place. The quinonoid possibilities can thus be varied at will, but no definite distinction can be drawn between them, the conversion of a salt-forming group into the quinonoid form depending simply on its relative basicity.—J. B.

Flavonols ; The conversion of benzalcumaranones into ——. K. v. Auwers and P. Pohl. Annalen, 1914, **405**, 243—294.

An investigation of the general applicability of the syntheses of 2-methylflavonol from the dibromide of benzal-4-methylcumaranon-2) by the action of alkali described by Auwers and Müller (Ber., 1908, **41**, 4233). The conclusion is that a flavonol can only result when the necessary opening of the cumaranone ring takes place more easily than the splitting-off of hydrogen halide. The reaction takes place thus :



It is facilitated by the presence of a methyl, methoxy, or chlorine group *para* to the oxygen of the cumaranone ring, whilst methyl or methoxy groups in the *meta* position hinder the reaction, as does also the presence of two methoxy groups in the aldehyde residue. The method has the advantage that the cumaranones are easily accessible whereas the flavonones necessary in carrying out Kostanecki's process (this J., 1904, 367, 543) are not. Several syntheses of flavones are described.—J. B.

Phenyloxindole. R. Stollé. Ber., 1914, **47**, 2120—2122.

Phenyloxindole is readily obtained by heating chloroacetyldiphenylamine with aluminium chloride to 160—180° C. : $(C_6H_5)_2N{\cdot}CO{\cdot}CH_2{\cdot}Cl \rightarrow C_6H_4{<}\genfrac{}{}{0pt}{}{CH_2-}{N(C_6H_5)}{>}CO$. It condenses with phenylisatin to give diphenylisoindigotin (this J., 1909, 420, 831). The known ethyloxindole can also be prepared by this method from chloroacetylethylaniline. The condensation product of chloroacetylchloride and thiocresol is shown to be $CH_3.C_6H_4.S.CH_2.CO.Cl$ and not $CH_3.C_6H_4.S.CO.CH_2.Cl$, as stated by Auwers and Arndt (Ber., 1909, **42**, 544).—J. B.

o-Hydroxyazo-compounds derived from α-naphthol. G. Charrier and L. Casale. Gaz. chim. ital., 1914, **44**, I., 607—624.

By the action of diazonium salts on α-naphthol, there are formed, in addition to *p*-hydroxyazo-compounds, small quantities of *o*-hydroxyazo-derivatives, identical with the β-naphthoquinonearylhydrazones obtained by the action of the corresponding arylhydrazines on β-naphthoquinone. These *o*-derivatives are red crystalline substances, sparingly soluble in organic solvents, mostly insoluble in cold and slightly soluble in hot alkali solution, and soluble in concentrated sulphuric acid with a red colour, changing in a few cases to reddish-violet. 2-*p*-Anisylazo-1-naphthol is soluble in boiling dilute sodium hydroxide solution and forms a crystalline sodium salt.—A. S.

Patents.

Dyestuffs ; Process for preventing organic —— from forming dust. L. Cassella und Co. Ger. Pat. 274,642, Feb. 2, 1914.

The dyestuffs are ground with non-volatile, liquid or semi-liquid hydrocarbons, such as mineral oils. The incorporation of a small quantity of oil is sufficient for the purpose ; the dyestuffs can be worked up into powders, which are easily moistened by water and dissolve without difficulty.
—T. F. B.

Dyestuffs insoluble in water ; Process for converting —— into a finely divided condition. Badische Anilin und Soda Fabrik. Ger. Pat. 274,970, March 29, 1913. Addition to Ger. Pat. 222,191 (see this J., 1910, 1003).

The process described in Ger. Pat. 265,536 (first additional patent ; see this J., 1913, 1101) is modified by replacing the sulphite-cellulose lye by aromatic sulphonic or carboxylic acids, such as benzylated aminosulphonic acids, or amorphous, soluble aromatic sulphonic acids containing no hydroxyl groups, or phenolsulphonic acids or their condensation products with formaldehyde.—T. F. B.

Vat dyestuffs of the anthracene series ; Process for preparing ——. M. Kardos. Ger. Pat. 275,220, Jan. 30, 1913.

Anthracene-1.9-dicarboxylic acid imine or one of its halogen substitution products is fused with alkali, the melt is diluted with water, and the dyestuff is precipitated from the solution by treatment with air or other oxidising agent.—T. F. B.

Blue dyestuff from 1-aminonaphthalene-4.6.8-trisulphonic acid ; Process for preparing a —— by melting with alkaline sulphur compounds. Kalle und Co. A.-G. Ger. Pat. 275,449, June 8, 1913.

1-Aminonaphthalene-4.6.8-trisulphonic acid is melted with an alkaline sulphur compound, the melt is diluted with water, and the gases with reducing properties, or their compounds, are removed from the solution before separating the dyestuff ; this may be done by adding a suitable precipitant to the neutral or alkaline solution or by passing a current of air through the acidified solution. This results in a considerably increased yield of the dyestuff.—T. F. B.

Vat [anthracene] dyestuffs ; Red —— and process of making same. R. Herz. Frankfort, Germany, Assignor to Cassella Color Co., New York. U.S. Pat. 1,103,004, July 7, 1914. Date of appl., July 23, 1913.

V.—FIBRES ; TEXTILES ; CELLULOSE ; PAPER.

Paper standards and paper testing. C. F. Cross. Papierfab., 1914, **12**, 831—832.

THE primary physical properties involved in paper testing are : in breaking strain, the sectional area ; in specific volume-weight, the density or concentration of fibre-substance. In testing for strength, the breaking strain should be referred not only to the unit of sectional area of the strip but the results should also be calculated on the assumption that the area broken consists entirely of fibre-substance without air-space. The ratio of thickness of paper to absolute fibre-density should always be kept in view. The suggestion by Briggs (this J., 1914, 745) that breaking strain and volume, both referred to unit weight of paper-substance, should be combined additively to give an expression for "handle," is criticised, the author's view being that any combination of the two factors mentioned above should be expressed as a product. —J. F. B.

VII.—ACIDS ; ALKALIS ; SALTS ; NON-METALLIC ELEMENTS.

Ammonia ; Synthesis of —— by means of aluminium nitride. C. Matignon. Chem.-Zeit., 1914, **38**, 894—895, 909—910.

ERPEK has shown that when a current of nitrogen is passed hrough a mixture of alumina and carbon at 1800° C., the lumina is rapidly converted into aluminium nitride :— $Al_2O_3+3C+N_2=Al_2N_2+3CO-187{\cdot}6$ cal. The heats of ormation of the nitrides of the following metals, calculated n N_2, are :—Mg, 119·7 ; Ca, 111·2 ; Si, 90 ; Al, 110 cals. luminium combines directly with atmospheric nitrogen hen introduced at a high temperature into a flask conaining nitrogen, or if a mixture of aluminium powder and arbon is strongly heated and a current of nitrogen introuced through a carbon tube within the mass. A temperaure of 2000° C. is easily obtained in this way. Serpek's rocess can be accelerated, and effected at 1500° C., by he aid of the catalytic action of hydrogen and iron. n experiments at 1500° C. lasting an hour, in the presence f hydrogen, the product contained 12·85% N ; in the resence of iron, 7·7% and in the presence of both hydrogen nd iron 27·07%. Bauxite, containing iron oxide can herefore be used for the process, and subsequent decompoition of the nitride yields ammonia and pure alumina. he nitride is heated under pressure with a solution of dium aluminate of 20°—21° B. (sp. gr. 1·162—1·171), and he alumina is then thrown down by adding some preipitated alumina, the solution being used again without rther concentration. The cost of preparing alumina om the nitride in this way is about half that of reparing it from bauxite by heating under pressure with ustic soda and sodium aluminate of 40° B. (sp. gr. 1·383). hen the process is worked solely for the production of mmonia, the alumina is not purified, and the decomposion of the nitride is simpler. A furnace for the manufacre of aluminium nitride by Serpek's process comprises a xed chamber arranged between two inclined rotating ylindrical chambers which open into it. The lower of these tating chambers contains a resistance and forms an ectric furnace ; the lining is of aluminium nitride. auxite is fed into the upper end of the upper rotating hamber and passes downwards through the chambers, uxing with carbon which is fed into the fixed chamber, nd meeting a current of nitrogen which is admitted at the wer end of the electric furnace. The carbon monoxide rmed in the reaction is burnt at the lower end of the upper hamber, and serves to preheat the bauxite. Each of the tating chambers is 25 m. long, and a current of 10,000 mperes at 230 volts is used.—A. T. L.

otassium carbonate ; An impurity of ——. W. Kohen. Chem.-Zeit., 1914, **38**, 898.

OTASSIUM carbonate, purified so as to yield no precipitate ith silver nitrate, often gives one after ignition. The thor has found this to be due to the presence of tassium chlorate, which is formed during the electrolytic duction of caustic potash and remains in the carbonate anufactured therefrom.—A. T. L.

Magnesium sulphate, sodium sulphate and sodium phosphate ; Commercial standards for dried ——. J. C. Umney and C. T. Bennett. Proc. Brit. Pharm. Conf., 1914, 23—24.

DRIED magnesium sulphate should be prepared by drying the crystalline salt at 100° C. till it has lost about a third of its weight and contains 23 to 31% H_2O. The product should be readily and completely soluble in water. Sodium sulphate can be readily dehydrated by heating for two hours at 100° C., and the dried salt should not contain more than 5% H_2O. The same limit should be adopted for sodium phosphate which can be prepared by drying the crystalline salt at 100° C.—F. SHDN.

Aluminium hydroxide ; Some reversible hydrosols derived from ——. R. P. Rose. Kolloid-Zeits., 1914, **15**, 1—7.

PRECIPITATED aluminium hydroxide if washed rapidly and dried slowly, *e.g.*, at 40°—80° C., becomes, during the drying, soluble in dilute acetic acid. Products of the composition, $Al_2O_3,7-6H_2O$, give very viscous solutions ; from $Al_2O_3,4{\cdot}5H_2O$ to $Al_2O_3,2{\cdot}75H_2O$, mobile, faintly opalescent solutions are obtained, and from $Al_2O_3,1{\cdot}9H_2O$ downwards solution no longer takes place. The most suitable concentration of acetic acid is 6—8% ; above 40% of acid, normal aluminium acetate is formed. The solutions produced are colloidal in character. Propionic, butyric, nitric (N/20—N/35), hydrochloric (N/20—N/35), hydrobromic (N/10—N/20), and hydriodic acid (N/5—N/12) also form hydrosols with the aluminium hydroxide under similar conditions. Sodium and potassium sulphates produce irreversible coagulation of the hydrosols, but the coagulation produced by boiling, by hydrochloric acid, or by the aluminium salt of the acid used in preparing the hydrosol, is reversible, the coagulum being redissolved on replacing the supernatant liquid by water. The disperse phase in the hydrosol is evidently a basic aluminium salt, and the view is expressed that the molecule of this basic salt is ionised to a certain degree, and that the reversible coagulation represents a phase of the law of mass-action as applied to the solubility product.—A. S.

Silicic acid gel ; Structure of ——. J. S. Anderson. Z. physik. Chem., 1914, **88**, 191—228.

EXPERIMENTS on the repeated dehydration and re-hydration of silicic acid gel are described, together with similar experiments using benzene and alcohol in place of water. The results are interpreted in accordance with Zsigmondy's view (this J., 1911, 1056) that the gel is permeated by extremely fine capillaries ; the average diameter of the largest capillaries is calculated to be 5·55 $\mu\mu$ and that of the smallest 2·63 $\mu\mu$. The specific gravities of the gel substance, of the dried gel, and of the gel saturated with water were found to be 2·048, 0·980 and 1·500 respectively. No evidence of the formation of hydrates was observed. —A. S.

Nickel oxide and protoxide ; Tariff treatment of —— in Sweden. Board of Trade J., July 30, 1914. [T.R.]

A SWEDISH Royal Decree, dated the 13th May, 1914, provides that *nickel oxide* and *nickel protoxide* shall be added to the list of duty-free chemicals included under No. 1163 of the Swedish Customs Tariff. This Decree is to take effect from the 1st January, 1915.

Acetic acid for industrial purposes in Belgium. Board of Trade J., July 30, 1914. [T.R.]

A DECREE of the Belgian Minister of Finance, dated the 17th July, provides that foreign acetic acid imported into Belgium by manufacturers who are known to require acetic acid in their manufacturing processes, may, under a permit issued by the Administration, be admitted at the following reduced rates of duty :—

Acetic acid containing in pure acetic acid—

40% or less, 3 frs. per hectolitre (1·3d. per gall.).
More than 40% up to 60%. 4½ frs. per hectolitre (2d.).
More than 60% up to 80%, 6 frs. per hectolitre (2·6d.).
More than 80%, 7½ frs. per hectolitre (3¼d.).

Acetic acid imported at these reduced rates must, before delivery to the importer, be denatured in the presence of the Customs officers, so as to render it unfit for comestible purposes.

[*Note.*—Hitherto foreign acetic acid for industrial purposes has been allowed to be imported *free* of Customs duty by virtue of Article 3 of the Law of the 11th June, 1887, and the Decree of the 13th June, 1887.]

Patents.

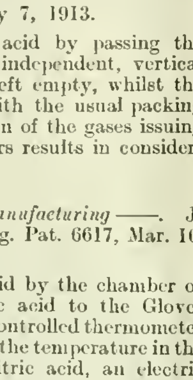
Sulphuric acid ; Process and apparatus for the manufacture of ——. J. F. Carmichael, Liverpool, and F. Guillaume, Brussels. Eng. Pat. 15,679, July 7, 1913.

In the manufacture of sulphuric acid by passing the reacting gases through a series of independent, vertical chambers, alternate chambers are left empty, whilst the intermediate chambers are filled with the usual packing materials ; the consequent expansion of the gases issuing from the packed chambers or towers results in considerably increased yields.—O. R.

Sulphuric acid ; Process of manufacturing ——. J. Lutjens, Hanover, Germany. Eng. Pat. 6617, Mar. 16, 1914.

In the manufacture of sulphuric acid by the chamber or tower process, the supply of nitric acid to the Glover tower is regulated by an electrically-controlled thermometer situated in the lead chamber. When the temperature in the chamber falls, owing to lack of nitric acid, an electric circuit is closed, operating a valve which admits nitric acid to the Glover tower, and *vice versa*.—O. R.

Sulphuric acid ; Water-spraying device, especially for the manufacture of —— *in lead chambers.* Harkortsche Bergwerke und Chem. Fabriken zu Schwelm und Harkorten A.-G. Ger. Pat., 275,388, Nov. 16, 1913.



The spraying device (see fig.) consists of a casing of hard lead in two parts, *a* and *b*, screwed together, with a packing ring in between. In the lower part fits a glass vessel, *k*, having a central opening and provided with grooves which extend from the top to the bottom in a curved path and diminish in cross-section as they approach the central opening. A ball, *i*, of glass or the like rests in the vessel, *k*, and partly closes the grooves. The upper part, *c*, of the device is connected with the water supply and then flows out through the grooves mentioned, issuing from the opening, *g*, in the form of fine spray.—A. S.

Acetic acid from acetylene ; Process for producing ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 467,515, Jan. 20, 1914. Under Int. Conv., Feb. 21, 1913.

Acetylene is converted into acetic acid by passing it through a solution of hydrogen peroxide, persulphuric acid, monopersulphuric acid, or a salt of one of these acids, in presence of mercury or a mercury compound. *Example:* A current of acetylene (10·8 parts by weight) is passed into a mixture of 250 parts of 20 to 30% sulphuric acid, 100 parts of 95% ammonium persulphate, and 5 to 10 parts of mercuric oxide, the temperature being kept between 30° and 40° C. The resulting liquid contains 24 to 25 parts of acetic acid.—T. F. B.

Acetic acid from acetylene ; Electrolytic process for producing ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 467,778, Jan. 27, 1914. Under Int. Conv., March 27, 1913.

The anodic oxidation of acetylene to acetic acid can be effected in a satisfactory manner by using a solution of sulphuric acid or other acid solution as electrolyte, in presence of a mercury compound. *Example.* The anode compartment of an electrolytic cell, with clay diaphragm and lead anode, is filled with 30% sulphuric acid containing 1 to 2% of mercuric oxide : the cathode, which may be of lead or copper, is also in 30% sulphuric acid. Acetylene is introduced into the anode compartment at the rate of 48·5 grms. per hour for every 100 amps. The current used may be 5 to 15 amps. per sq. decimetre of anode surface at 3 to 4·5 volts, and the electrolyte is kept at 30° to 40° C. The yield of acetic acid amounts to 0·5 kilo. or more per litre of anolyte in 24 hours.—T. F. B.

Salt for culinary purposes. G. W. Malcolm, Northwich, and The Salt Union Ltd., Liverpool. Eng. Pat. 29,053, Dec. 16, 1913.

Common salt is moulded in the form of cubes, blocks, or the like, each of which contains a predetermined quantity of salt (where the amounts of salt used are in tablespoonfuls, cupfuls, etc., etc.), suitable for culinary purposes.—O. R.

Rare earth metals ; Process for the manufacture of compounds of the ——. Gebr. Siemens und Co., Berlin-Lichtenberg, Germany. Eng. Pat. 8015, March 30, 1914. Under Int. Conv., April 1, 1913.

Rare metals are rapidly precipitated from their solutions as fluorides, by the addition of ground fluorspar and a little hydrochloric acid, the mixture being preferably heated and stirred. Ground apatite may be used instead of fluorspar, phosphates of the earths being precipitated. —O. R.

Magnesium carbonate from magnesian limestone ; Process of manufacturing ——. F. S. Young, Newark, N.J. U.S. Pat. 1,101,772, June 30, 1914 ; date of appl., Oct. 6, 1909.

Magnesian limestone is calcined, hydrated, suspended in water, and carbonated at atmospheric pressure, with the formation of magnesium bicarbonate solution and the precipitation of calcium carbonate.—O. R.

Amalgams of alkali and alkaline-earth metals ; Process for the decomposition of ——. M. Helbig. Ger. Pat. 275,047, Aug. 17, 1913.

In the electrolytic production of alkali and alkaline-earth hydroxides with the aid of mercury cathodes, the decomposition of the amalgam is accelerated by the additio thereto, or to the reaction liquid, of small quantities o vanadium, molybdenum, or tungsten, alone or distribute on a suitable support, or in the form of an alloy or chemica compound. Under these conditions, the amalgam is decomposed as rapidly as it is formed, and a nearly theoretica current yield can be obtained with a relatively smal quantity of mercury and in a simple form of apparatus —A. S.

Barium aluminate ; Process for obtaining ——. C. A Beringer. Ger. Pat. 275,287, March 5, 1913.

A mixture of barium sulphate, a substance containin aluminium silicate, and a reducing agent is heated for long time to bright redness with burnt lime or limeston or substances, *e.g.* calcareous marl, containing the sam in order to convert the silica into calcium silicate. F example a finely powdered mixture of : clay 100, heav spar 84, carbon 35, and slaked lime 120 parts is heated f 8 hours at 1200° C., and barium aluminate is extract from the product by lixiviation with water. The residu calcium silicate is suitable for use in the manufacture cement.—A. S.

Thionyl chloride ; Manufacture of ——. P. A. Newto London. From Farbenfabr. vorm. F. Bayer und C Elberfeld, Germany. Eng. Pat. 27,830, Dec. 3, 1913.

Thionyl chloride is obtained by the interaction of sulph or sulphur monochloride with chlorine and chlorosulpho acid or of sulphur dichloride with chlorosulphonic aci with or without addition of a catalyst, such as antimo trichloride or mercuric chloride.—A. S.

Thionyl chloride ; Manufacture of ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 275,378, April 16, 1913.

THIONYL chloride is produced by the interaction of sulphur trioxide and sulphur dichloride at the ordinary temperature and pressure, in presence of suitable catalysts, *e.g.*, antimony trichloride, mercuric chloride, or other chlorides of heavy metals.—A. S.

Hydrogen peroxide solutions ; Process for preventing the decomposition of ——. A. Farago and H. Gonda. Ger. Pat. 275,440, Oct. 29, 1913. Under Int. Conv., April 30, 1913.

THE solutions are saturated with oxygen and kept in closed vessels in which a high pressure is maintained by means of a gas, preferably oxygen.—A. S.

Hydrogen peroxide ; Process for increasing the stability of —— in neutral liquid or solid media. E. Merck. Ger. Pat. 275,499, June 1, 1912.

THE stability of aqueous solutions of hydrogen peroxide or f solid compounds containing loosely-combined hydrogen eroxide is increased by addition of small quantities of eutral acyl esters of aminohydroxycarboxylic acids. -Benzoylhydroxy-β-dimethylamino*iso*butyric acid, benzoylecgonine, and α-benzoyl-β-piperidopropionic acid are pecially suitable.—A. S.

ir : Separation of oxygen from ——. L. Bergfeld, Durlach, Germany. Eng. Pat. 21,211, Sept. 19, 1913.

HE object of the invention is to obtain oxygen from the ir. Nitric acid vapours are passed over heated sulphuric cid to form oxygen, water, and nitrosyl sulphuric acid ; he last-named is treated with water to form sulphuric acid nd nitrous anhydride, nitric acid being re-formed from he nitrous anhydride by means of water and atmospheric xygen. The equations are : $2HNO_3=2NO_2+H_2O+O$;

$$2H_2SO_4+2NO_2=2HO.SO_2.O(NO)+H_2O+O\ ;$$

$$2HO.SO_2.O(NO)+H_2O=2H_2SO_4+N_2O_3\ ;\ \text{and}$$

$_2O_3+O_2+H_2O=2HNO_3$. The cycle of reactions is arried out continuously in a system of refractory and cid-proof tubes, acting as heat interchangers on the ounter-current principle, the tubes being preferably acked with quartz grains or the like, which offer resistance the flow of fluids, and facilitate the interchange of eat.—O. R.

ulphuric acid anhydride ; Process for producing —— according to the contact process. H. von Kéler and A. Weindel, Leverkusen, Germany, Assignors to General Chemical Co., New York. U.S. Pat. 1,102,670, July 7, 1914. Date of appl., June 23, 1913.

EE Fr. Pat. 460,074 of 1913 ; this J., 1914, 22.—T. F. B.

inc sulphate solution : Preparing pure ——. S. Araki, Osaka, Japan. Eng. Pat. 15,546, July 5, 1913. Under Int. Conv., Sept. 8, 1912.

E Fr. Pat. 464,038 of 1913 ; this J., 1914, 484.—T. F. B.

itrides ; Purification of mixtures containing ——. C. Bosch and A. Mittasch, Assignors to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 1,102,715, July 7, 1914. Date of appl., June 20, 1910.

E Fr. Pat. 418,059 of 1910 ; this J., 1911, 26.—T. F. B.

yanamide : Production of ——. M. Engelmann and B. Merkel. Assignors to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 1,102,892, July 7, 1914. Date of appl., Feb. 27, 1912.

E Eng. Pat. 2311 of 1912 ; this J., 1912, 900.—T. F. B.

lphur and sulphates ; Process of producing ——. C. Hansen, Leverkusen, Assignor to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 1,102,911, July 7, 1914. Date of appl., June 30, 1913.

E Ger. Pat. 264,920 of 1912 ; this J., 1913, 1068.—T. F. B.

Cream of tartar ; Manufacture of ——. H. Cantoni, Voghera, Italy, and J. Chautems and E. Degrange, Assignors to Cantoni, Chautems et Cie., and E. Degrange, Geneva. U.S. Pat. 1,103,658, July 14, 1914. Date of appl., Feb. 8, 1912.

SEE Fr. Pat. 426,714 of 1911 ; this J., 1911, 956.—T. F. B.

Reducing agents ; Process for making stable —— from rapidly oxidisable substances which are difficult to use, such as sodium, potassium, calcium, phosphorus, and similar substances. P. Goldstein. Fr. Pat. 466,853, Dec. 23, 1913. Under Int. Conv., Dec. 23, 1912.

SEE Ger. Pat. 268,657 of 1912 ; this J., 1914, 201.—T. F. B.

Base-exchanging substances containing silicic acid, alumina, and bases ; Process for making ——. Permutit-Akt.-Ges. Fr. Pat. 467,300, Jan. 14, 1914. Under Int. Conv., April 30, 1913.

SEE Eng. Pat. 1039 of 1914 ; this J., 1914, 549.—T. F. B.

Hydrogen peroxide solutions ; Process for preventing the decomposition of ——. A. Farago and H. Gonda. Fr. Pat. 467,103, Jan. 8, 1914. Under Int. Conv., April 30, 1913.

SEE Ger. Pat. 275,440 ; preceding.—T. F. B.

VIII.—GLASS ; CERAMICS.

PATENTS.

Glass [rod] manufacture ; Apparatus for ——. The British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 17,602, July 31, 1913.

A NUMBER of gripping devices travelling continuously up and down above a bath of molten glass, seize an initial length of solidified glass rod, which has been started by means of a bait, and draw it upwards. Towards the end of the upward travel of each of the carriages, on which the gripping devices are mounted, means are actuated for severing the rod below the point where it is gripped, and the detached length of glass rod is swung over the top of the machine and deposited in a receiver. The gripping devices then descend and remain open until they come into position again on the upward path, and seize a fresh rod of glass, which is already held and being drawn upwards by a gripping device higher up.—O. R.

Furnaces for melting glass or metals. J. Lambot, Marcinelle-Charleroi, Belgium. Eng. Pat. 29,813, Dec. 27, 1913.

In a tilting furnace for melting glass or metals, a detachable head is arranged at each end of the hearth, and is water-jacketed around the port, which communicates with the gas-supply flue, fixed in the axis of rotation of the furnace. A circular connection is fixed to the water-jacket to secure a tight joint, and another port is provided in the head, communicating with a movable and detachable hot air flue; the latter is secured to the head, and communicates in turn with the conduit of one of the regenerators, through a connection ensuring a tight joint, whatever be the position of the furnace. To form such a connection, the lateral faces of the water-jacket are enclosed in a frame of asbestos sheets secured to the upper portion of a metal frame, the lower edge of which rests in a groove filled with sand, two of the faces of the jacket being flat, and two being so curved as to remain in contact with the edges of the asbestos frame, whatever be the position of the movable flue. By this means communication between the hearth and the regenerators is ensured during tilting as well as during melting.—O. R.

Thin-walled articles from substances other than clay, but which can be moulded and burnt in a similar manner to ceramic materials; Manufacture of very ——. E. Podszus. Ger. Pat. 274,847, April 19, 1912.

The process is for the preparation of thin-walled articles from such substances as thoria, zirconia, rare earths, alumina, silica, boron nitride, and carbon. A permanent mould made of material having a low coefficient of expansion is used. It is coated first with a thin layer of paraffin, ceresin, wax, or ozokerite, and then with a layer of the refractory substance previously made into a thin paste. After the paste has set or dried, the layer of paraffin or the like is removed by warming or by means of a solvent, whereupon the shaped article of refractory material can be withdrawn from the mould. The surface of the intermediate layer of paraffin or the like may be roughened or rubbed over with graphite to make it adhere well to the layer of refractory material, or a layer of gelatin, collodion or the like may be applied before the refractory material. If the layer of gelatin or collodion be made sufficiently thick it may be withdrawn, after removing the intermediate layer, and will then itself serve as a mould.—A. S

Illuminating-glass; Method and batch or mixture for making ——. G. A. Macbeth, Assignor to Macbeth-Evans Glass Co., Pittsburg. Reissue No. 13,766, July 7, 1914, of U.S. Pat. 1,097,600, May 19, 1914. Date of appl., June 9, 1914.

See this J., 1914, 693.—T. F. B.

Furnace for melting glass or metals; Tilting ——. J. Lambot. Fr. Pat. 466,664, Dec. 26, 1913. Under Int Conv., Jan. 30, 1913.

See Eng. Pat. 29,813 of 1913; preceding.—T. F. B.

Porcelain and similar substances; Apparatus for baking —— *in continuous furnaces with movable hearths.* E. G. Faugeron, Assignor to Soc. Anon. des Faienceries de Creil et Montereau, Montereau, France. U.S. Pat. 1,103,184, July 14, 1914. Date of appl., Oct. 11, 1911.

See Fr. Pat. 421,765 of 1910; this J., 1911, 424.—T. F. B.

IX.—BUILDING MATERIALS.

Portland cement raw materials; Burning tests of Philippine ——. A. P. West and A. J. Cox. Philippine J. Sci., 1914, 9, 79—102.

Cement made in an experimental gas-fired stationary kiln, from local materials (chiefly limestone and volcanic tuff), mixed so that the ratios, $SiO_2 : R_2O_3$ and $CaO : (SiO_2 + R_2O_3)$, and the cementation index, are within the usual technical limits, was found to be sound and of high specific gravity and tensile strength.—F. Sodn.

Wood; Preliminary work in fire-proofing ——. R. E. Prince. Proc. Amer. Wood Preservers' Assoc., 1914, 158—172.

The apparatus for testing inflammability consisted of a quartz cylinder, 3 ins. in diam. and 10 ins. long wound with nichrome ribbon of high electrical resistance and insulated with asbestos. The apparatus was heated electrically, natural draught was used, and the temperature of the air inside the cylinder indicated by a thermocouple pyrometer. Test pieces, 1¼ ins. square, by 4 ins. long, were impregnated with concentrated solutions under 100 lb. pressure per sq. in. The pieces, containing 6% of moisture, were placed in the cylinder previously heated to 200° C. and allowed to remain until the gases ignited at a small pilot-light 1 inch above the test-piece and set fire to the wood or, in default, for 40 mins. The tests were repeated at temperature-increments of 50° C. If the wood ignited the time was noted and the piece dropped into a chamber below the cylinder; it was allowed to burn for 3 mins. and the loss of weight recorded. Of untreated woods tamarack was the most resistant and redwood next. Of the chemical impregnating agents, oxalic acid, sodium carbonate and bicarbonate were inefficient in retarding combustion and weakened the wood. Ammonium salts were most effective, while borax was also of considerable value.—J. F. B.

Wood preservatives [creosote oil]; Report of the Committee on ——. Proc. Amer. Wood Preservers' Assoc., 1914, 58—76.

The definition of creosote oil is revised, and comprises all distillate oils boiling between 200° and 400° C., obtained by direct distillation from tars consisting principally of compounds of the aromatic series and containing well-defined amounts of phenoloids. The most important tests are: those for moisture, specific gravity and distillation. Additional tests are: for free carbon, tar acids, sulphonation; the Hempel distillation test, refractive indices and specific gravities of the fractions. These tests are described in detail with the apparatus employed. All temperature observations must be made with a standard thermometer of specified dimensions, length of stem from 0° to 400° C., 295 mm., bulb 14 mm. long and 6 mm. in diam. Readings to be uncorrected. No recommendations have yet been formulated as to standard specifications for creosote oils but the specifications enforced by several consumers associations are reprinted collectively for comparison.
—J. F. B.

Creosote in well preserved timbers; Quantity and character o ——. G. Alleman. Proc. Amer. Wood Preservers Assoc., 1914, 88—96.

The creosote oils extracted from timber which had been i use many years showed an average of 32·9% of distillat below 270° C. and 66·8 of oils of high boiling point. Th defects of most modern creosote preservatives are deficienc in basic oils of high boiling point and the substitution f these of tar or other viscous substances. Under prop conditions of distillation a stable, heavy creosote oil (sp. g 1·10) could be manufactured from coal tar, containin nothing which boils below 210° C.; for general purpos not more than 50% of the total should distil below 315° and for wood-paving blocks not more than 35%. Th qualities demanded are penetrating power, stability, ar preservative and water-proofing value. All these a possessed in a high degree by pure heavy creosote o Tar has a very low penetrating power, even when injecte at a high temperature, and wood treated with a mixtu shows a separation of the components: oil, tar and carbo at the margins of the close-grain rings. As regards stabilit losses occur owing to volatilisation, extraction by wat and crystallisation in wood impregnated with light creos oils. Preservative value may depend on direct antisep action or permanent adhesion of a stable oil-coating to t walls of the minutest cells; external filming without pe tration is of little account. In the light oils the antisep constituents predominate but are volatile and larg soluble in water. The heavy oils are sufficiently rich in t higher homologues of cresols, both these and the protect oils being far more stable. Waterproofing also depe on the complete coating of the cell walls with an oily dep which excludes moisture.—J. F. B.

Creosoting industry ; Use of refined coal tar in the ——. H. von Schrenk and A. L. Kammerer. Proc. Amer. Wood Preservers' Assoc., 1914, 99—148.

The efficiency and permanence of the preservative effect of creosote oils depend on the proportion of oils boiling above 235° C., and this corresponds inversely with the rate of evaporation in open dishes or in timber test-blocks. The best results are always obtained with a heavy oil equivalent to the No. 1 specification of the Amer. Railway Eng. Assoc., but the supply of such oils is limited and far short of the demand. The blending of a small proportion of refined coal-tar enables inferior oils to be used with more satisfactory results, as regards permanence, than are obtained with such oils in the pure state. Eighty parts of the inferior creosote oil should be thoroughly mixed with 20 parts of coke-oven coal-tar, containing not more than 5—6% of carbon, at 180° F. (83° C.) and the temperature of the mixture during impregnation should not be below this. The penetrating power of the mixture is not less than that of creosote oil if the time under pressure be slightly increased. The separation of the tarry components from the oil in the pores of the wood is denied and the superior retention of the oil is proved experimentally.—J. F. B.

Wood-preserving industry in the United States, 1913. Board of Trade J., July 23, 1914. [T.R.]

Returns from 93 wood-preserving plants, of which 58 are commercial plants and 35 private plants (of these 20 are operated by railway companies), show that in 1913 these plants treated 153,613,888 cubic ft. of material, or 21·9% more than in 1912. The total consumption of creosote oil by these plants in 1913 was 108,373,359 (American) galls., an increase of 29·5% over the previous year; the consumption of zinc chloride amounted to 26,466,803 lb., an increase of 27·5%, and of miscellaneous liquid preservatives 3,885,738 galls., an increase of 26·4%. The quantity of creosote imported in 1913 was 62% of the total amount used. New plants for the manufacture of creosote oil are, however, being erected in the middle west and, if present plans materialise, should add about 10,000,000 gallons annually to the available supply of creosote.

Patents.

Kilns or ovens for calcining lime, cement, and other material. F. Crosland, Liscard, Cheshire, and R. Booth, London. Eng. Pat. 22,173, Oct. 2, 1913.

To prolong the life of the lining of vertical shaft kilns, and o preheat the material before calcination, the kiln lining s oval or elliptical in shape from the gas ports upwards to desired point, the wall itself being vertical: from the upper end of the vertical wall to a desired point higher up, he lining is twisted in the shape of a spiral, and from the upper end of the spiral, the section of the kiln becomes ircular, finally widening into hopper form at the summit. —O. R.

Food ; Process for preserving ——. W. Lichty. Ger. Pat. 274,662, July 23, 1913.

Food is impregnated with solutions of lead chloride and ercuric chloride, which may be applied consecutively or imultaneously.—T. F. B.

ement : Process of and furnace for manufacturing ——. L. P. Basset, Montmorency, France. Eng. Pat. 15,612, July 7, 1913.

ee Fr. Pat. 457,511 of 1912 ; this J., 1913, 1012. Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the atents and Designs Act, 1907, to Eng. Pats. 9545 of 94 and 24,620 of 1909.—T. F. B.

rocess for obtaining barium aluminate. Ger. Pat. 275,287. *See* VII.

X.—METALS ; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Cyaniding ; Calcium hydroxide for ——. R. K. Meade. Eng. and Min. J., 1914, 98, 52—53.

Slaked lime prepared by rotating quicklime crushed to pea-size in a steel drum with slight excess of water, and sifted from the coarse particles, is preferable to quicklime. —W. R. S.

Copper and zinc ; New researches on the alloys of ——. L. Guillet. Bull. Soc. d'Encour., 1914, 121, 14—56.

A series of pure Cu-Zn alloys with Cu from 56 to 100% was subjected to mechanical tests after rolling, in some cases after rolling and drawing, and also after working and annealing. The annealed samples showed a simple relation between the tensile strength and the Brinell hardness. Rolling (hot and cold) had a considerable influence on the properties of the alloys, but the effects were eliminated by annealing. Quenching increased the hardness. For industrial use, alloys with not less than 72% Cu are recommended.—T. St.

Bronzes ; Three-metal ——. A. M. Blow. Met. and Chem. Eng., 1914, 12, 461—467.

A description of the ternary systems: copper-tin with lead, zinc, phosphorus, manganese and aluminium. *Lead* imparts plasticity to bronze, and diminishes hardness and temperature changes ("imparts a lower mutual freezing point"). Microscopic examination shows that the lead is distributed throughout the mass. Segregation, to which bronzes rich in lead are liable, is prevented by the addition of 1% Ni, sulphur added in the form of galena, phosphorus, or arsenic. A small addition of *zinc* does not materially alter the structure of bronzes, whilst ductility and tensile strength are slightly increased. Bronzes containing zinc are more easily forged and cold-rolled and less readily corroded by sea-water. *Phosphorus* may exist entirely as solid solution (up to 1%) or as Cu_3P ; it greatly increases the hardness and resistance to wear, whilst impairing the tensile strength, elasticity and elongation. The maximum in commercial bronzes is about 0·8% P, with about 8% Sn. The valuable properties of *manganese* bronze are its strength and non-corrodibility; commercial products often contain more aluminium than manganese. True *aluminium* bronze seldom contains more than 11% Al; it is useful in casting, though it shrinks considerably. The addition of tin increases its ductility.—W. R. S.

Lead, copper, zinc, tin, aluminium, nickel, mercury, and silver ; World's production of ——. Board of Trade J., Aug. 6, 1914. [T.R.]

According to a statistical summary and report compiled by the "Metallbank und Metallurgische Gesellschaft," Frankfort-on-Maine, the total production of these metals during the last three years has been :—

	1911.	1912.	1913.
	Metric tons.	Metric tons.	Metric tons.
Lead	1,136,000	1,181,800	1,186,700
Copper	893,800	1,018,600	1,005,900
Zinc	902,100	977,900	997,900
Tin	117,600	124,700	128,900
Aluminium	45,000	62,600	68,200
Nickel	24,500	28,500	30,000*
Mercury	4,100	4,300	4,200
Silver, fine	7,685	7,745	..

*Estimated.

Steel production in the United States. Eng. and Min. J., Aug. 1, 1914. [T.R.]

The Statistical Bureau of the American Iron and Steel Association states that the production of steel in the United States in 1913 was the largest ever reported. A further decrease in the make of Bessemer or converter steel, and a large increase in open-hearth steel, chiefly basic metal, are noteworthy.

The production in 1912 and 1913 was :—

	1912.	1913.
	Tons.	Tons.
Bessemer	10,327,901	9,545,706
Open-hearth	20,780,723	21,599,931
Crucible	121,517	121,226
Electric	18,309	30,180
Miscellaneous	2,853	3,831
Total	31,251,303	31,300,874

Included in the open-hearth steel are 1,255,305 tons made by the acid process and 2,210,718 tons produced by the duplex process, made from metal partly treated in Bessemer converters and finally purified in open-hearth furnaces. This is an increase of 772,064 tons over the previous year.

In 1913 the production of steel treated with ferro-vanadium, ferrotitanium, nickel and other alloys was 714.357 tons, a decrease of 78,144 tons from 1912. The total included 74,924 tons Bessemer steel, 213,404 acid open-hearth, 386,486 basic open-hearth, 28,279 crucible and 11.264 tons electric and miscellaneous steel.

At the close of 1913 there were 30 plants equipped to make steel by the standard Bessemer process and 80 by the Tropenas or other modifications of that process. There were 119 basic and 93 acid open-hearth plants, 29 of them being equipped to make both acid and open-hearth steel. There were 110 crucible steel plants and 19 electric plants.

Mineral output of the Philippine Islands in 1913. Board of Trade J., July 30, 1914. [T.R.]

The following statistics have been obtained from the Mines Department of the Bureau of Science of the Philippine Islands showing the mineral output of the islands in 1913, as compared with 1912 :—

	1912.		1913.	
	Quantity	Value.	Quantity.	Value.
		Dollars.		Dollars.
Iron .. metric tons	141	24,636*	227	32.235*
Silver .. fine ounces	7,121	4.332	Not stated	Not stated
Gold .. „	27,582	570.212	42,011	868,362
Coal .. metric tons	2.720	10.100	Not stated	Not stated
Clay products	—	226.500	—	230,000
Lime .. metric tons	—	46,013	11,050	51,350
Sand and gravel cubic metres	—	234,375	689.011	297,823
Stone „	—	325.525	197.039	175.020
Salt .. metric tons	19,147	287,255	19,500	287,500

* The statistics for iron represent the quantity and value of iron castings, mostly ploughshares.

Mineral products mined or manufactured but not sold at the end of each year are not included in the foregoing figures.

Mineral production of Canada in 1913. J. McLeish. Min. and Eng. World, July 18, 1914. [T.R.]

The preliminary report on mineral production in Canada in 1913 shows a total value of $144,031,047, made up as shown in the following table :—

Metallic.

Product.	Quantity.	Value.
Copper, at 15.269 cts., lb.	76,975,832	$11,753,440
Gold, oz.	784.525	16.216,131
Pig iron, tons	73.508	996.429
Iron ore sold, tons	216.614	430,561
Lead, at 4.659 cts., lb.	37,662,703	1,754,705
Nickel, at 30 cts., lb.	49.676.772	14,903,032
Silver, at 59.791 cts., oz.	31,750,618	18,984.012
Cobalt and nickel oxides	—	689.511
Zinc ore, tons	7,535	400,000
Total		$66,127,821

Non-metallic.

Actinolite, tons	66	$720
Arsenic, white, tons	1,692	101,463
Asbestos, tons	136,951	3,830,909
Asbestic, tons	24,135	19,016
Coal, tons	15,115,089	36,250,311
Corundum, tons	1,177	137,036
Feldspar, tons	15,935	56,841
Graphite, tons	2.162	90.282
Grindstones, tons	4,284	43,900
Gypsum, tons	639,698	1,477,589
Magnesite, tons	770	4,620
Mica, tons	—	170,112
Mineral pigments—		
Barytes, tons	641	6,410
Ochres, tons	5,987	41,774
Mineral water	—	173,677
Natural gas, per M	20,345,763	3.338,314
Peat, tons	2,600	10,100
Petroleum, at $1.782 brls.	228,080	406,439
Phosphate, tons	25	217
Pyrites, tons	228,811	638,185
Quartz, tons	78,261	169,842
Salt, tons	100,791	491,280
Talc, tons	12,250	45,980
Tripolite, tons	620	12,138
Total	—	$47,517,155

Structural materials and clay products.

Cement, Portland, brls.	8,658,922	$11,227,284
Clay products—		
Brick, common, pressed, paving	—	7,709,224
Sewer pipe	—	920,973
Fire clay, drain tile, pottery, etc.	—	1,037,870
Kaolin, tons	500	5,000
Lime, bus.	7,671,381	1,605,812
Sand and gravel	—	1,712,256
Sand-lime brick	—	962,004
Slate, sq.	1,432	6.444
Stone—		
Granite	—	1,644,183
Limestone	—	3,087,991
Marble	—	250,373
Sandstone	—	216,657
Total structural materials and clay products	—	$30,386,071
All other non-metallic	—	47,517,155
Total value, metallic	—	66,127,821
Grand total, 1913	—	$144,031,047

Smelter production.—The total quantity of ore, concentrates, etc., treated in 1913, was 3,027,085 tons as compared with 3,005,410 tons in 1912. The ores treated may be classified as follows :—

	1912.	1913.
	Tons.	Tons.
Nickel-copper ores	725,065	823.403
Silver-cobalt-nickel-arsenic ores	8,097	5,818
Lead and other ores treated in lead furnaces	59.932	78,110
Copper-gold-silver ores	2,212,316	2,119,754
Total	3,005,410	3,027,085

The products obtained in Canada from the treatment of these ores include refined lead produced at Trail, B.C., and fine gold, fine silver, copper sulphate, and antimony produced from the residues of the lead refinery there silver bullion, white arsenic, nickel oxide and cobalt oxid produced in Ontario from the Cobalt district ores. I addition to these refined products, blister copper, coppe matte, nickel-copper matte, cobalt material or mixe cobalt and nickel oxides are produced and exported fo refining outside of Canada.

Refined products produced and metals contained in refined smelter products exported.	1913	
	Refined products.	Metals contained in matte, bliste base bulli and speiss
Gold, oz.	11,977	213,279
Silver, oz.	13,789,709	934,601
Lead (including secondary lead), lb.	39,468,729	—
Copper, lb.	—	59,245 722
Copper sulphate, lb.	130,533	—
Nickel, lb.	—	49,676,772
Nickel and cobalt oxides, etc., lb.	1,644,185	
White arsenic, lb.	3,384,249	—

The aggregate results of smelting and refining operations may be summarized as in the above table. The figures do not represent the total production from smelting ores mined in Canada since considerable quantities of copper and silver ores are still shipped to other smelters outside Canada for smelting.

Smelter products shipped out of Canada for refining were blister copper carrying gold and silver values 15,270 tons in 1913, as compared with 17,063 tons in 1912, copper matte carrying gold and silver values 5159 tons in 1913 as against 6727 tons in 1912 and Bessemer nickel-copper matte carrying small gold and silver values as well as metals of the platinum group 47,150 tons in 1913 as compared with 41,925 tons in 1912.

PATENTS.

Metal; Means for stirring or agitating molten —— in melting pots. I. Hall, Birmingham. Eng. Pats. 15,323, 23,493, and 24,081, July 3, Oct. 7 and Oct. 24, 1913.

THE dish-shaped stirrer fits fairly closely into the bottom of the melting pot, and its outer edge is turned upwards and is provided with annular corrugations. Perforations are arranged at or near the angle where the turned-up portion commences. A central sleeve, attached to the solid central part of the dish, surrounds the stem of a valve which controls a central tapping hole. The dish is worked upwards and downwards by a lever attached to the sleeve and pivoted on the furnace edge. Modified forms have perforated radial blades attached to the sleeve, and means for imparting a rotary motion to the dished member. —T. St.

Metals; Composite ——. The British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, U.S.A. Eng. Pat. 19,021, Aug. 21, 1913.

METAL of the general character of Monel metal (Ni 2, Cu 1) is united to steel by means of an intermediate film of copper. Plates of the two metals, with a sheet of copper between, are heated in hydrogen or in a vacuum to somewhat above the melting point of copper, but below the melting-point of the other metals. The composite sheet may be rolled or otherwise worked without danger of the components separating.—T. St.

Waste heat of slags; Method and apparatus for utilising the ——. C. Semmler. First Addition, dated Dec. 4, 1913, to Fr. Pat. 463,298, Oct. 6, 1913 (this J., 1914, 426).

THE receptacles into which molten slag is run, are surrounded by closed-in vessels full of water. A reservoir situated at a higher level communicates with the water vessels by pipes through which a natural circulation of the water takes place. The steam produced, assists the circulation. Various forms embodying this principle are described.—T. St.

Furnaces; Calcining and roasting ——. E. Cornet. First Addition, dated Jan. 8, 1914, to Fr. Pat. 465,302, Nov. 25, 1913 (this J., 1914, 540).

THE lower portion of the furnace containing the calcined product is surrounded by an annular chamber, or independent segmental chambers, containing refractory chequer-work in which the incoming air is strongly heated. The central conduit which admits air into the centre of the charge, to complete the oxidation of carbon monoxide, is also provided with chequer-work. The iron bars of the framework of the annular preheaters may be hollow so as to allow of water cooling.—T. St.

Furnace for roasting ores. P. Piketty. Fr. Pat. 466,991, Jan. 5, 1914.

A SHAFT furnace is built up on a framework of reinforced concrete. The walls are formed of independent slabs of concrete with asbestos in the joints. The lining is composed of refractory bricks, vertical grooves being left for air cooling.—T. St.

Alloys of high melting point; Manufacture of ——. Wolfram Lampen Akt.-Ges. Fr. Pat. 466,737, Dec. 30, 1913. Under Int. Conv., Aug. 19, 1913.

IN making ductile alloys of high melting point from one of the metals Cr, V, Nb, Ta, Os, Ru, Th, Zr, and W, with a small amount of another of the same metals, a very small amount (1/2000 of the total mass) of a metal of the platinum group is added to the mixture before compression, to act as a catalytic agent in facilitating the formation of an alloy, or solid solution.—T. St.

Ores; Method of agglomerating and simultaneously transforming —— before smelting. R. E. Trottier. Fr. Pat. 467,301, March 26, 1913.

THE ore is agglomerated with the coal necessary for reduction and the necessary flux so that the briquettes can be treated in a blast-furnace direct without other additions. The briquettes may be heated to dull redness out of contact with air, or in a reducing atmosphere, before charging into the blast-furnace, whereby volatile constituents of the ore are driven off, the distillation products of the coal are recovered, and the metal is partly reduced. —T. St.

Agglomeration of iron ores; Process for increasing the output of rotary kilns especially as used for the ——. G. Polysius, Eisengiesserei und Maschinenfabrik. Ger. Pat. 275,582, Feb. 8, 1913.

BESIDES the main burner a second burner is provided, the flame from which is directed to that part of the kiln where the finer material, which is not or only partly agglomerated, accumulates. The two burners may form branches from a common fuel- and air-supply pipe.—A. S.

Plated metals; Process for removing the coating from —— by means of mercury, with recovery of the latter by distillation. K. Albert, E. Ellenberger, and C. von der Linde. Ger. Pat. 275,105, Sept. 13, 1912.

THE plated metal is treated with mercury vapour, which condenses and forms with the coating metal a liquid amalgam. The residual mercury adhering to the metal, and unused mercury vapour, are distilled from the reaction vessel and recovered. The process, which is applicable to the treatment of iron coated with zinc, copper, lead, tin, brass, or nickel-copper alloys, may be carried out wholly or partly in a vacuum.—A. S.

Briquettes from iron ore and flue dust; Manufacture of ——. M. Freiberger, Charlottenburg, Germany. Eng. Pat. 15,919, July 10, 1913. Under Int. Conv., July 10, 1912.

SEE Fr. Pat. 460,954 of 1913; this J., 1914, 85.—T. F. B.

Iron or manganese metal; Process of manufacturing —— from pure or impure iron or manganese-metal oxides. C. A. Brackelsberg, Stockum, Germany. U.S. Pat. 1,103,258, July 14, 1914. Date of appl., Dec. 11, 1911.

SEE Ger. Pat. 241,321 of 1910; this J., 1912, 136.—T. F. B.

Pyrophoric alloy. P. Faehr, Bitterfeld, Assignor to Elektrochemische Werke G.m.b. H., Berlin. U.S. Pat. 1,102,575, July 7, 1914. Date of appl., March 27, 1912.

See Fr. Pat. 439,058 of 1912; this J., 1912, 648.—T. F. B.

Alloy for welding copper and nickel. C. Canzler and R. Samesreuther, Düren, Assignors to Autogenwerk Sirius Ges. m. b. H., Dusseldorf, Germany. U.S. Pat. 1,103,482, July 14, 1914. Date of appl., Sept. 24, 1913.

See Fr. Pat. 461,942 of 1913; this J., 1914, 205.—T. F. B.

Alloy; Metallic ——. C. E. Monkhouse. Fr. Pat. 467,487, Jan. 20, 1914. Under Int. Conv., Jan. 22, 1913.

See Eng. Pat. 1819 of 1913; this J., 1914, 87.—T. F. B.

Minerals; Process for treatment of —— and extracting metal. B. Junquera, Oviedo, Spain. U.S. Pat. 1,102,339, July 7, 1914. Date of appl., Dec. 18, 1908.

See Fr. Pat. 394,719 of 1908; this J., 1909, 370.—T. F. B.

Ore concentration. H. H. Greenway, Clare, South Australia, and A. H. P. Lowry, Prahran, Victoria. U.S. Pat. 1,102,738, July 7, 1914. Date of appl., May 17, 1913.

See Fr. Pat. 458,051 of 1913; this J., 1913, 1078.—T. F. B.

Ore concentration. (1) G. A. Chapman and S. Tucker, (2) G. A. Chapman. Assignors to Minerals Separation, Ltd., London. U.S. Pats. 1,102,873 and 1,102,874, July 7, 1914. Dates of appl., Dec. 26, 1912, and May 8, 1913.

See Eng. Pats. 28,929 of 1911 and 12,171 of 1912; this J., 1913, 146.—T. F. B.

Ores and similar substances; Process and apparatus for preparing [concentrating] ——. G. S. A. Appelqvist and E. O. E. Tydén. Fr. Pat. 467,018, Jan. 5, 1914. Under Int. Conv., Jan. 6, 1913.

See Eng. Pat. 402 of 1913; this J., 1913, 430.—T. F. B.

Filter for slimes pulp and the like. G. Ridgway, Kalgoorlie, Western Australia. U.S. Pat. 1,103,080, July 14, 1914. Date of appl., Feb. 3, 1912.

See Eng. Pat. 10,731 of 1912; this J., 1913, 608.—T. F. B.

Gold and silver from refractory ores; Recovery of ——. C. Butters, London. U.S. Pat. 1,103,346, July 14, 1914. Date of appl., Aug. 28, 1912.

See Eng. Pat. 18,660 of 1912; this J., 1913, 915.—T. F. B.

Nickel; Extraction of —— from mixtures of nickel and other metals. H. E. Fierz, Basle, Switzerland. U.S. Pat. 1,103,747, July 14, 1914. Date of appl., March 26, 1914.

See Eng. Pat. 4249 of 1913; this J., 1913, 870.—T. F. B.

Nickel; Recovery of —— from its ores. The Madagascar Minerals Synd., Ltd. First Addition, dated Feb. 15, 1913, to Fr. Pat. 463,615, Dec. 21, 1912.

See Eng. Pats. 27,626 of 1912 and 3814 and 6703 of 1913; this J., 1914, 30.—T. F. B.

Nickel; Recovery of —— from its ores. The Madagascar Minerals Synd., Ltd. Second Addition, dated March 22, 1913, to Fr. Pat. 463,615, Dec. 21, 1912.

See Eng. Pats. 6703, 17,131, and 18,769 of 1913; this J., 1914, 30, 489.—T. F. B.

Metals; Process for extracting ——. MacKay Copper Process Co. Fr. Pat. 465,614, Dec. 3, 1913.

See U.S. Pat. 1,094,371 of 1914; this J., 1914, 598.—T. F. B.

Copper; Process for hardening ——. W. H. White. Fr. Pat. 467,583, Jan. 22, 1914.

See U.S. Pat. 1,062,067 of 1913; this J., 1913, 662.—T. F. B.

Furnaces for melting glass or metals. Eng. Pat. 29,313. *See* VIII.

XI.—ELECTRO-CHEMISTRY.

Patents.

Accumulators; Alkaline electric ——. E. Foss, F. Harris and B. W. Parker, London. Eng. Pat. 16,027, July 11 1913.

Positive electrodes of nickel or cobalt hydroxide, an negative ones of iron monoxide or sesquioxide, are contained in a box partly filled with granulated pumice ston saturated with caustic potash solution.—B. N.

Wood for storage-battery separators; Process of treating ——. J. M. Skinner, Assignor to Philadelphia Storage Battery Co., Philadelphia. U.S. Pat. 1,098,357, May 26, 1914. Date of appl., Dec. 26, 1912.

Wood separators for storage batteries are immersed in an aqueous solution of sodium sulphide or other sulphide at 15° to 100° C.; they are removed before the fibres and cells are disintegrated, and are then washed and dried under pressure. The object of this treatment is to remove some of the constituents objectionable for battery purposes, and to make the wood more porous.—T. F. B.

Furnaces; Electric ——. I. Rennerfelt, Stockholm, Sweden. Eng. Pat. 226, Jan. 5, 1914. Under Int. Conv., Jan. 4, 1913.

Electrodes, for the production of arcs, are supported in stationary brickwork portion of the furnace, and within this portion the bottom, supporting a number of crucibles arranged in a circle underneath the electrodes, is rotated round a vertical axis. The arcs play directly on to arbon, or other conducting material, supported on a rojection fixed to the movable bottom, and the roof of the urnace radiates the heat rays on to the crucibles. Burners, or oil or gas, may be located in the stationary portion as supplementary source of heat.—B. N.

using refractory materials; Process for ——. E. Podszus, Berlin-Treptow, Germany. Eng. Pat. 27,744, Dec. 2, 1913. Under Int. Conv., Dec. 2, 1912.

ee Fr. Pat. 465,604 of 1913; this J., 1914, 700.—T. F. B.

lectrolytic apparatus. W. Thum, Hammond, Ind., U.S.A. Eng. Pat. 9232, April 14, 1914.

urnace; Electric ——. A. Minet and H. L. L. Lucas, Paris. U.S. Pat. 1,103,309, July 14, 1914. Date of appl., Dec. 30, 1913.

ee Eng. Pat. 12,444 of 1913; this J., 1913, 1159.—T. F. B.

lectric arcs; Method of generating heat by means of ——. I. Rennerfelt, Stockholm. U.S. Pat. 1,103,379, July 14, 1914. Date of appl., March 18, 1913.

ee Fr. Pat. 466,291 of 1913; this J., 1914, 599.—T. F. B.

l used for electrical purposes; Process of regenerating ——. R. Friese, Charlottenburg. Assignor to Siemens-Schuckertwerke G. m. b. H., Berlin. U.S. Pat. 1,103,499, July 14, 1914. Date of appl., April 1. 1913.

ee Eng. Pat. 8130 of 1913; this J., 1913, 950.—T. F. B.

lectrolytic process for producing acetic acid from acetylene. Fr. Pat. 467,778. *See* VII.

mposition of amalgams of alkali and alkaline-earth metals. Ger. Pat. 275,047. *See* VII.

XII.—FATS; OILS; WAXES.

an oil extracting mill at Dairen. Board of Trade J., Aug. 6. 1914. [T.R.]

he new experimental bean-mill belonging to the South anchuria Railway Company (see this J., 1914, 756) arted operations in the middle of April last. The mill situated at Ji-ji-ko, about two miles from the Dairen harves, and cost about £30,000, of which the plant cost out £20,000. It is equipped for the manufacture crude oil and bean meal from soya beans, and for fining the crude oil obtained. The maximum capacity the mill is 80 tons of beans per day of 24 hours. At esent only 50 tons are used daily, producing 7 tons of oil and 40 tons of meal. The crude oil is not at present refined at the mill as there are no operatives sufficiently trained to work the refining plant.

Owing to the low percentage of moisture and oil in the residue obtained by this process, it will be possible to export this residue to Europe for use as a cattle food, and trial shipments for this purpose are to be made. At present the residue is sold in Japan as a fertiliser. It fetches a higher price by 20% than bean cake; but from equal quantities of beans the residue obtained is 20% less than the amount of bean cake obtained by the crushing method, whilst there is the additional expense of providing bags for packing.

It is too early to say whether the experiment will give satisfactory results from a commercial point of view. The capital cost is much greater than for a mill of the ordinary type and more skilful operatives are necessary. The crude oil contains benzine and is therefore unsuitable for edible purposes—its chief use in China; for this reason it has fetched lower prices than the oil from the crushing mills The oil must therefore be refined before being put on the market, and it will probably be necessary to find a market in Europe or America.

Kukui and lumbang oils. Oil, Paint, and Drug Rep., July 27, 1914. [T.R.]

There is very little if any difference between the kukui nut of Hawaii and the lumbang nuts, *Aleurites moluccana* and *Aleurites triloba*, found in the Philippines. Kukui-nut oil is a valuable Hawaiian product and is in demand in the paint and varnish trade. It has been shipped to the United States from various Pacific islands for the last 75 years. The kukui-nut oil of Hawaii, like the lumbang oil of the Philippines, has very pronounced drying properties and is said to be suitable for all purposes for which linseed oil is used. The kukui-nut press cake is rich in nitrogen, phosphoric acid, and potash, and is highly prized as a fertiliser. This is also true of the lumbang cake of the Philippines. There seems to be some difference of opinion as to the value of these cakes as a fodder, but most feeders consider them poisonous. The oils are generally considered as unfit for human consumption on account of their pronounced purgative properties.

An oil is made in the Philippines from the nuts of *Aleurites tri-sperma*, locally called "lumbang banucalad," which is asserted to be practically identical with Chinese tung oil.

Soya bean oil for paint making in Australia; Denaturation of ——. Board of Trade J., July 30, 1914. [T.R.]

The following formula has been approved, under the provisions of By-Law No. 231, for the denaturation of soya bean oil for paint making:—

Soya bean oil	85	gallons
Linseed oil, double boiled	15	„

Oil so denatured may be delivered free of duty under Tariff heading No. 234 (H).

Hardened oils in Europe. Oil, Paint and Drug Rep., July 20, 1914. [T.R.]

Artificially hardened liquid oils are now being supplied in large quantities, both in Europe and in the United States. On account of the relatively lower price of linseed oil during the past year, this has been more generally hardened for the soap makers than the other oils. Whale oil is also coming into use for this purpose. Cottonseed oil, being relatively high in price, is not being hardened in important quantities except for edible uses. In the United States most of the large makers of compound lard, who formerly used 80% of liquid cottonseed oil and 20% oleo-stearin, now use cottonseed oil exclusively, after hardening it to the desired consistency. In Europe small quantities of cottonseed oil are being hardened for margarine, and this will probably be an important business, but for the present most of the hardened oils are being used for soap. The total capacity of European hardening plants for 1914 is put at 1,375,000 barrels (400 lb. each), but not more than half this amount was made in 1913. In the United States the output for 1913 is put at 500,000 barrels, and the plants are said to be rapidly increasing.

The amounts of various oils used in the principal European countries in 1913 for making margarine are estimated at:—Copra oil, 169,000 metric tons; palm kernel oil, 35,000; animal hard fats, 143,500; liquid oils, 150,000 tons. The production of margarine is increasing year by year, and copra oil as an ingredient is becoming increasingly popular. The demand for this purpose alone will probably be 250,000 tons in 1914, and this is two-thirds of the world's crop. The soap trade will always require important quantities. The copra crop of 1913 is estimated at 630,000 metric tons. At the highest probable yield of 60%, this would make 378,000 metric tons of oil.

PATENTS.

Wagon- and machine-grease; Manufacture of ——. A. Schmitt, geb. Zannowsky. Ger. Pat. 274,209, Aug. 29, 1911.

In the preparation of lubricating greases, a solution of sodium aluminate is used instead of calcium oxide or hydroxide to effect saponification of saponifiable oils or fats dissolved in mineral oils. Aluminium hydroxide in a very fine state of division, and possessing considerable lubricating value, is precipitated in the mass.—A. S.

Lubricants and substances for adding thereto; Manufacture of —— *capable of indicating "hot running."* W. Esch. Ger. Pat. 275,055, April 22, 1913.

Naphthalene-sulphur (prepared by melting together equal weights of naphthalene and sulphur) is incorporated with the lubricant by heating, and after cooling, burnt magnesia or equivalent oxides, hydroxides, peroxides or the like, may also be incorporated with the mass. If a bearing lubricated with this preparation becomes heated, hydrogen sulphide is evolved.—A. S.

Trimethylamine derivatives for use in preparing soaps, candles, ointments, finishing materials, or for other purposes for which stearine is used; Process for making ——. M. Herzmann. Ger. Pat. 275,344, June 15, 1911.

Trimethylamine is treated, first at the ordinary temperature and then at about 120° C. under pressure, with the chlorohydroxy-fatty acids or sulphuric esters of hydroxy fatty acids, such as Turkey-red oil, obtainable from higher unsaturated fatty acids; a small quantity of a catalyst, such as finely divided copper or pyridine, facilitates the reaction. The products thus obtained contain the carboxyl group intact, and can therefore be saponified with alkalis; on the other hand, owing to their basic properties, they can combine with oxalic and other acids to form salts.—T. F. B.

Wood-oil; Process of preserving —— *from congealing on being subjected to heat.* E. Beringer and W. Zimmer, Charlottenburg, Assignors to Reichhold, Flügger und Böcking, Hamburg, Germany. U.S. Pat. 1,103,473, July 14, 1914. Date of appl., Sept. 23, 1913.

See Ger. Pat. 261,403 of 1912; this J., 1913, 834.—T. F. B.

Apparatus for testing lubricants. Ger. Pat. 275,225. *See* XXIII.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

PATENTS.

Plastic masses; Process for preparing solid ——. K. Hagendorf. Ger. Pat. 274,179, July 29, 1913.

Serum from the blood of cattle is treated with formic acid and trioxymethylene or formaldehyde, and then heated with phenol and sodium peroxide until a solid product is obtained.—T. F. B.

Paints and printing colours; Manufacture of ——. N. W. Turkin. Fr. Pat. 467,039, Jan. 6, 1914.

See Eng. Pat. 23,128 of 1913; this J., 1914, 757.—T. F. B.

Paints, enamels, etc.; Process for making ——. International Color and Chemical Co., Inc. Fr. Pat. 467,464, Jan. 19, 1914. Under Int. Conv., Feb. 1, 1913.

See U.S. Pat. 1,084,361 of 1914; this J., 1914, 208.—T. F. B.

Cellulose nitrates; Solutions of —— *more especially applicable for lacquers.* A. G. Bloxam, London. From Act.-Ges. f. Anilinfabr., Treptow, Germany. Eng. Pat. 17,953, Aug. 6, 1913.

See Fr. Pat. 461,034 of 1913; this J., 1914, 93.—T. F. B.

Resin-soap and resin; Method for manufacturing ——. J. Aktschourin, Aktschourin-Tupik, Russia. U.S. Pat. 1,103,336, July 14, 1914. Date of appl., Jan. 8, 1913.

See Ger. Pat. 257,015 of 1912; this J., 1913, 499.—T. F. B.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Rubber solutions; Influence of the solvent on the viscosity of ——. F. Kirchhof. Kolloid-Zeits., 1914, **15**, 30—36.

The experiments were made with an Ostwald capillary viscometer as modified by Ubbelohde. Preliminary tests showed that with a working pressure corresponding tc 60 cm. of water the viscosity-coefficients of not too concentrated solutions were practically independent of the efflux-velocity. The viscosity-coefficients of 0·5, 1, 2, and 3% solutions of plantation rubber in carbon tetrachloride tetrachloroethane, and pentachloroethane respectivel were about double those of solutions of equal concentratio in benzene or petroleum benzine. According to Hatschek (Kolloid-Zeits., 1913, **12**, 238, **13**, 88), the viscosity of a emulsoid sol. depends upon the ratio of the total volum to the volume of the disperse phase, in that this rati $A=\left(\frac{\eta}{\eta-1}\right)^3$, where η is the viscosity coefficient; and th values for the volume of the disperse phase calculated b the aid of this formula showed that the rubber in th disperse phase was combined with many times its ow volume of solvent; the quantity of solvent thus combine was different for different solvents and varied with tl concentration of the solution. When the concentratio of the solutions were calculated on the basis of the volun of the disperse phase, values were obtained which we in agreement with the enormous increase of viscosi observed with solutions containing more than 1% dissolved rubber.—A. S.

PATENTS.

Rubber compounds. J. F. Monnot, Paris. Eng. P 16,033, July 11, 1913.

Durability of rubber tyres is increased and tendency skid lessened by making them with a mixture of Pa rubber, 15; sulphur, 1·8; litharge, 1·5: magnesi carbonate, 1·8; whitening, 1·7; zinc oxide, 5·0, a finely ground "ruby arpax or telium," 3·2 kilos.—D. J.

Rubber; Apparatus for evaporating the moisture out coagulated ——. Bertrams Ltd., R. F. Gillespie a P. M. Matthew, Edinburgh. Eng. Pat. 16,372, July 1913.

Rubber is carried on a continuous band or the like fr the coagulating machine through rollers into a dry chamber, from which the moist air may be forced out drawn off. Partitions in the drying chamber cause air to follow a tortuous path, and the band passing c rollers is caused to travel up and down the chamber d present an extended drying surface.—D. J. L.

Rubber; Process for regenerating old ——. L. Sachs. Ger. Pat. 275,061, Feb. 11, 1913.

Finely subdivided rubber waste is treated with a mixture of a metallic sulphite and an oil capable of combining with sulphur, at a high temperature and preferably under increased pressure.—T. F. B.

Caoutchouc, guttapercha, and like substances; Treatment of ——. L. Feval and J. de la Fresnaye, Paris. U.S. Pat. 1,102,487, July 7, 1914. Date of appl., Aug. 11, 1913.

See Eng. Pat. 17,582 of 1913: this J., 1913, 1078.—T. F. B.

Rubber: Process for accelerating the vulcanisation of natural or artificial ——. Farbenfabr. vorm. F. Bayer und Co. First Addition, dated Dec. 29, 1913, to Fr. Pat. 464,533, Nov. 7, 1913. Under Int. Conv., Feb. 25, 1913.

See Ger. Pat. 269,512 of 1913; this J., 1914, 365.—T. F. B.

XV.—LEATHER; BONE; HORN; GLUE.

Salt stains: The salting of hides and the avoidance of so-called ——. E. Romana and G. Baldracco. Collegium, 1914. 517—519.

Fresh hides were carefully washed in running water and tumbled in running water for half an hour. They were then laid on the horse, hair side out, allowed to drain for 12 hours, and afterwards salted with 15% of denatured salt with an addition of 1% (on the weight of salt) of various other salts (sodium fluoride and sulphate, potassium carbonate, chloride and borax). After salting the hides were left in pile for 24 hours, then bundled in the usual way and left for 15 days. They were found to be perfectly preserved, the hair being firm and the flesh quite clear. After soaking back, and washing out the salt, the hides were limed in a lime liquor to which sodium sulphide had been added, fleshed and delimed. In every case the grain was white and without stains. It is concluded that salt stains are caused by impurities contained in the hide, and that to obtain good results it is indispensable to wash the hides well before salting.—D. J. L.

Tanning effects of various quinones; The comparative ——. L. Meunier and A. Seyewetz. Collegium, 1914, 523—527.

The authors have shown previously (this J., 1908, 580, 909) that a product of great stability, having all the physical and chemical characters of true leather, is produced by the action of benzoquinone on the amidogen groups of the albumin molecule. The reaction is accompanied by an oxidation of the fibre, resulting in the transformation of part of the quinone into quinol (hydroquinone) thus:—

$$R.NH_2+2C_6H_4O_2=R.N:C_6H_1O_2+C_6H_4(OH)_2.$$
$$2R.NH_2+3C_6H_4O_2=(R.N)_2:C_6H_4O_2+2C_6H_4(OH)_2.$$

The tanning properties of various substituted quinones have been compared with those of ordinary benzoquinone with regard to their power of rendering gelatin insoluble and their rapidity of penetration. 5 grms. of gelatin in thin sheets was soaked in distilled water for 2 hours, then placed in flasks with 200 c.c. of recently boiled distilled water containing respectively 0·2, 0 15, 0·10 and 0·05 grm. of each of the various substituted quinones. The flasks were kept in the dark and the resistance of the gelatin to boiling water was measured after 18, 68, 96 and 120 hours. Benzoquinone in very dilute solutions did not render gelatin insoluble instantaneously, but only after an appreciable lapse of time. In 120 hours, 5 grms. of gelatin were rendered insoluble by 0·05 grm. of quinone in 200 c.c. of water. Higher homologues of quinone, at concentrations lower than 0·1%. did not render gelatin insoluble in 120 hours. The chlorine, sulphonated, chloro-sulphonated and bromo-sulphonated derivatives of quinone had a more rapid tanning action than quinone itself. At very great dilutions their action seemed to be a surface effect. All the sulphonated derivatives were used in the form of their sodium salts; their tanning action would be modified by the presence of an acid. In determining penetrating power tubes were used containing 5 c.c. of 4% gelatin solution and 15 c.c. of 0·2% solutions of the quinones. The degree of penetration was followed by observing the reddish brown colour of the gelatin when tanned by the quinones. All the sulphonated, chloro-sulphonated and bromo-sulphonated quinones which had a rapid tanning action coloured and tanned the outer surface of the gelatin rapidly but the penetrating action was very weak and the lower part of the gelatin remained untanned. The slower acting quinones such as toluquinone penetrated slowly but regularly. The action of ordinary benzoquinone was intermediate between that of the two types. Quinones thus resemble natural tannins in the fact that the more rapid their tanning action the feebler is their penetrating power.—D. J. L.

Gambier; Chinese block ——. E. O. Sommerhoff and C. Apostolo. Collegium, 1914, 7, 504—509.

The mineral matter, *e.g.*, magnesium salts, in tanning extracts exists as a kind of complex salt with the tannin, analogous to the combination of magnesium in chlorophyll. A kind of dongola tannage takes place when these extracts are used, even when no extra mineral substance is added. In the yellow powder deposited from Indragiri gambier in hot water, 1·5% of ash was found; the dissolved matter yielded 4·9% ash. Comparative analyses of the ash of Chinese and Indragiri gambier are given; the Chinese gambier contains more alkali salts while the Indragiri contains more magnesium salts. The difference in the method of extraction is held responsible for the different composition of the ash. The Chinese gambier was extracted in an open vessel in the light and air, while the Indragiri was extracted in a closed battery. By dissolving in boiling water and stirring in the light the red Indragiri gambier becomes yellow and similar to the Chinese. By stirring, relatively dilute gambier solution can be caused to coagulate. In both kinds of gambier 0·52% of nitrogen was found, corresponding to 3·5% dry vegetable albumin. This nitrogen has been disregarded in the determination of the amount of loading silk fibre has undergone when gambier has been used for the purpose. Gambier consists of sparingly soluble catechin and more easily soluble catechintannic acid. The substance which is generally regarded as being fixed by the hide cells is the catechin which is sparingly soluble in water but soluble in ether, while the catechintannic acid, insoluble in ether, is easily soluble in water, and washed out from the leather to a great extent.—D. J. L.

Mangrove in quebracho extracts: van Gijn and van der Waerden's method for the detection of ——. W. Moeller. Collegium, 1914, 485—487. (See this J., 1914, 151.)

The presence of methylpentosans in a tanning extract is not always due to mangrove, and their absence is no proof that mangrove is not present. Furfural is volatilised in the process of manufacture and by drastic treatment all furfural and methylfurfural may be removed from mangrove or quebracho or any other extract. Quebracho wood contains 14% and oak bark 16% of pentosans but their extracts contain none. Mangrove wood contains both pentosans and methylpentosans but the extract only methylpentosans. As the boiling point of methylfurfural is 20° higher than that of furfural, more of the former is left in the extract after the manufacturing process. Methylfurfural is formed in mangrove extract during manufacture and may be removed almost quantitatively by distillation at 110° C. in a vacuum without adding hydrochloric acid; it is not removed by shaking out with ether, being apparently in a loosely combined form. Methylfurfural is destroyed by other chemical treatment besides sulphiting as found by van Gijn, and quebracho extract may contain 50% of mangrove without showing it by the test. A small quantity of methylfurfural found in an extract shows the probability of the presence of mangrove, but it may be derived from other materials. Many other barks beside that originally known as mangrove bark appear in trade under the same name, and all barks giving a red extract and containing much tannin are now called mangrove. Some samples of so-called mangrove bark give a value of 30—40% when shaken out with ethyl acetate (see this J., 1914, 94), while real mangrove, according to Stiasny, should yield only 0—5%.—D. J. L.

Barks; Valuation of birch —— by von Schroeder's hydrometer method. W Appelius. Collegium, 1914, 399—402.

A table is given showing the connection between the specific gravity of birch bark liquors and the percentage of total extract and tannin contained in them. The tannin content was, on the average, 10% by the official method and 9% by the Löwenthal method. An average of 3·7% of sugar was found, and, per 100 parts of tannin, 93—94 parts of non-tannins and 35 parts of saccharine substances. —D. J. L.

Tanning extracts, and in leather; Cellulose extracts and their detection in ——. W. Moeller. Collegium, 1914, 488—493. (See also this J., 1914, 365, 654.)

The substances in cellulose extract which react with aniline and hydrochloric acid are all contained in the portion of it which is absorbed by hide. That the non-tannin filtrate sometimes gives the precipitate is due to the fact that many cellulose extracts are neutral or alkaline, and the material reacts very slowly with hide powder. Cellulose extract was detected in the suspender pits of a tannery in which its use had been discontinued for 6 months. By adding absolute alcohol to a fairly strong cellulose extract solution 40—50% is precipitated, which is quite a different action to that shown by most tanning materials. The precipitate contains all the substance which gives the Procter-Hirst reaction (this J., 1909, 293), and the portion left in solution is free from lignin. By reprecipitating the lignin substance was obtained as an oily liquid which was evaporated to a solid extract consisting mainly of substances absorbed by hide. The alcoholic filtrate contained very little material capable of being absorbed by hide and did not react with aniline. Small quantities of cellulose extract mixed with other extracts can be detected by precipitating with alcohol and applying the Procter-Hirst test to the dissolved precipitate. The author found it impossible to detect cellulose extract in leather in the manufacture of which it had been used mixed with other extracts in the ordinary course of manufacture. When cellulose extract has been used as a filling and weighting material on tanned leather it can be washed out with water and the Procter-Hirst test applied.—D. J. L.

Leather and in sulphited extracts; Sulphuric acid in ——. U. J. Thuau and R. Madru. Collegium, 1914, 527—533.

A great quantity of leather, in the manufacture of which no sulphuric acid has been used, is refused for use in the French army as containing too much sulphuric acid. The quasi-official method of determination of Balland and Maljean is inaccurate, amorphous sulphur, sulphur of sulphites and bisulphites and all organic sulphur being converted by it into sulphuric acid and estimated as such. The presence of sulphur is necessary in many leathers. Dufour has investigated the behaviour of organic sulphur under the Balland method and has attempted to isolate the tanning matter from sulphited extracts and separate from it the inorganic sulphites and sulphates. 20 c.c. of $N/10$ hydrochloric acid was added to 5 grms., sulphited extract of 25° Bé. (1·21 sp. gr.) in 100 c.c. of water. The tannin was precipitated with a 5% solution of cinchonine hydrochloride and the precipitate washed, dried, and burnt in an electric muffle furnace. The solution of the ash in dilute nitric acid gave no precipitate with barium chloride. On repeating the experiment and adding 10—15 c.c. of $N/1$ sodium carbonate to the tannin precipitate before burning, much precipitate was obtained with barium chloride. An extract sulphited with 10% of bisulphite and containing 40% tannin showed 1·094% SO_3. A leather tanned with this extract and containing 40% tannin would thus show the same percentage of SO_3 by Balland's method but would appear basic by Procter's method. Chestnut and oak wood extracts contain organic acids and when sulphited or mixed with a sulphited extract, free sulphuric acid may be formed and may appear in the leather. Sulphates and sulphites may be estimated accurately to 3% by the following method. Sulphates are first estimated by precipitation with barium chloride. A known weight of the extract is evaporated with sodium carbonate and potassium nitrate and ignited, and sulphates estimated in the ash. The difference between the two is calculated as sulphurous acid. Free sulphurous acid is estimated by distilling into standard soda solution, oxidising with bromine water and precipitating as sulphate. The rate at which sulphurous acid is driven off by boiling is some guide as to the behaviour of the extract in practice. Extracts sulphited under pressure give off much less sulphurous acid than others. In the first case sulphonation probably takes place, and the Balland and Maljean method would not distinguish between free sulphuric acid and SO_3 combined in this form.—D. J. L.

Patents.

Tannin; Process for extracting —— from bark, wood or other vegetable materials and apparatus for carrying out the said process. S. B. Bilbrough and J. Frew, Johannesburg. Eng. Pat. 14,405, June 21, 1913.

The material is subjected to a preliminary mechanical crushing to render it absorbent and afterwards to a series of crushings or squeezings prior to one or more of which it is soaked with tannin liquor or water. The material is delivered direct from one set of rollers to the next by conveyors or carriers set between the rollers, and pumps deliver the tan liquors expressed from each set of rollers through pipes which spray the liquors on the material issuing from the preceding set of rollers. Means are provided for applying two or more washes prior to any or all of the stages of pressing, each wash being followed by one or more pressings. Flanges are provided to prevent the bark pulp or fibre from spreading beyond the ends of the rollers.—D. J. L.

Tannin and dyestuff extracts; Process for preparing an agent for decolorising and clarifying —— from soya beans. E. Dammer. Ger. Pat. 274,974, Feb. 2, 1913.

Soya beans are ground, freed mechanically from oil, and dried, and these processes are repeated several times, the husks and starch particles being removed. This treatment renders the protein substances insoluble, and yields a product suitable for decolorising and clarifying tannin and dyestuff extracts, by virtue of its power of precipitating colouring matters without affecting the tannin.—T. F. B.

Hides; Method of storing ——. W. H. Allen, Detroit, Mich. U.S. Pat. 1,098,005, May 26, 1914; date of appl., March 12, 1913.

Tanned hides are kept in a condition suitable for dyein by storing them whilst still wet in a chamber of which th atmosphere is kept saturated with moisture and an anti septic such as formaldehyde. The hides before storin may be treated with an antiseptic and should be raise on supports to keep them off the floor of the chamber —D. J. L.

Leather; Process for decolorising ——. R. Friedrich Ger. Pat. 275,304, July 16, 1913.

Vegetable-tanned hides are immersed in a dilute solutio of aluminium bisulphite, or of a mixture of aluminiu sulphate and sodium bisulphite; treatment with a dilut alkali carbonate solution may precede the bisulphit treatment when hides tanned with mangrove and simila extracts and then dried and finished, are to be bleache —T. F. B.

Adhesive substance; Production of an —— of a lig colour from seaweeds. A. Krefting, Assignor to Nor Tangsyndikat, Christiania, Norway. U.S. Pa 1,099,382, June 9, 1914. Date of appl., Feb. 21, 191

The outer dark-coloured skin is removed from the stal of sea-weeds by grinding, cutting or slitting. The stal re then cut into smaller pieces, leached with water and ibjected to a treatment with chemicals to effect dissotion.—D. J. L.

rotein-containing materials [*soya-beans*]; *Preparation of plastic substances* [*artificial horn, bone, etc.*] *from* ——. R. Dodd and H. B. P. Humphries, London. Eng. Pat. 15,316, July 3, 1913.

SEMI-PLASTIC material is prepared from the soya bean y removing the bulk of the oil, macerating and extracting ith water, separating the insoluble and non-emulsifiable ibstances from the liquors or paste so obtained and agulating the liquor either warm or cold with aluminium lphate or formaldehyde. Suitable glutinous, colouring, ling, hardening or other materials may afterwards be lded.—D. J. L.

anning. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 18,258, Aug. 11, 1913.

E Addition of July 31, 1913, to Fr. Pat. 443,730 of 1912; is J., 1914, 209.—T. F. B.

tins; Process for preparing —— for tanning and dyeing. E. d'Huart. Fr. Pat. 466,562, Oct. 20, 1913.

E Eng. Pat. 23,841 of 1913; this J., 1914, 326.—T. F. B.

XVI.—SOILS; FERTILISERS.

itrification and denitrification in arable soils: Influence of organic matter on ——. A. Kossowicz. Z. Gärungsphysiol., 1914, **4**, 1—48. Chem. Zentr., 1914, **2**, 260—261.

HE experiments were made on an alluvial loam soil. itrification was retarded by peptone and to a lesser extent a mixture of peptone and straw, and also by very large iantities of straw alone. Dried farm manure had a ght retarding action, and dried manure mixed with raw had a greater effect than old manure with straw. nitrification was greatly accelerated by straw and straw with peptone and in a still higher degree straw with manure; the ammonia-nitrogen formed the decomposition of peptone was rapidly nitrified. other experiments in which both ammonium lphate and potassium nitrate were added, the effect various substances on nitrification and denitrification gether was similar to that on nitrification alone. rbohydrates had no specially favourable influence on trification. The following substances had a progressively eater retarding effect on nitrification in the order given: ea, ammonium acetate, acetamide, asparagin, peptone. the case of peptone nitrification began only when all e peptone-nitrogen was converted into ammoniatrogen; formation of nitrate and nitrite began simulneously in nearly all cases. (See also Barthel, this J., 14, 759).—A. S.

Patent.

ag containing phosphoric acid; Process for increasing the solubility in citric acid of ——. Act.-Ges. Peiner Walzwerk, and H. Küppers. Fr. Pat. 467,111, Jan. 8, 1914.

E Eng. Pat. 922 of 1914; this J., 1914, 704.—T. F. B.

XVII.—SUGARS; STARCHES; GUMS.

aste waters; Report upon the work of the (*German*) *State Commission for the examination of methods of purifying beet sugar factory* ——. C. Günther and A. Herzfeld. Z. Ver. deut. Zuckerind., 1914, 139—168.

IL purification processes cannot be applied generally account of the large amount of land required. It is possible to find one method that will suit every case. The ne applies to the Proskowetz process (this J., 1912, 205) and its modifications; another disadvantage of the latter process is the "sliming" of the soil. Which process should be adopted depends upon a large number of factors, amongst which may be mentioned the nature and amount of land available, the possibility of enlarging the factory, and the relative prices of sugar and of beetroot slices. —J. P. O.

Determination of rhamnose in presence of other methylpentoses. Votocek and Potmesil. *See* XXIII

Patents.

Beet slices; Apparatus for the lixiviation of subdivided material, especially ——. W. Möhring. Ger. Pat. 273,960, April 14, 1912.

The apparatus comprises two smooth pipes of the same diameter, inclined to one another at an acute angle, and connected by a curved piece, at the lowest part of which is a juice outlet provided with a grating. The material is conveyed through the apparatus, under a constant degree of compression, by a suitable conveyor, which also acts as a scraper serving to prevent stoppage of the juice outlet. The shorter pipe, immediately below the feed hopper, is surrounded by a heating device.—A. S.

Sugar cane and other materials; Apparatus for obtaining juice from ——. O. Mengelbier. Ger. Pat. 274,462, Dec. 13, 1912. Addition to Ger. Pat. 261,999.

In the process described in the principal patent (this J., 1913, 920) the bagasse, on its way from one set of press rolls to another, was passed through a chamber divided into compartments, in one of which it was treated with steam and in others with sweet water or water. According to the present patent the compartments are formed by partitions fixed to the conveyor on which the bagasse is carried through the chamber.—A. S.

Sugar solutions; Clarification of ——. E. Köpke, Honolulu, Hawaii, Assignor to Köpke Clarifier Co. U.S. Pat. 1,101,940, June 30, 1914; appl., July 20, 1911.

Expressed juice is centrifuged to remove insoluble matter, the latter being extracted with water and centrifuged again. The solutions thus obtained are clarified, heated, and centrifuged to remove coagulated impurities. The coagulum is extracted with water and centrifuged, the clear solution obtained being concentrated and centrifuged.—L. E.

Molasses; Process for desaccharifying —— and boiling centrifugal syrup. A. Gräntzdörffer and A. List, Magdeburg, Germany. Eng. Pat. 15,957, July 10, 1913.

See Fr. Pat. 460,192 of 1913; this J., 1914, 36.—T. F. B.

XVIII.—FERMENTATION INDUSTRIES.

Yeast; Determination of glycogen in ——. E. Salkowski. Z. physiol. Chem., 1914, **92**, 75—88.

The author states that glycogen in yeast cannot be determined by the method and modifications thereof recently proposed (see Schönfeld and Künzel, this J., 1914, 155). The yeast gum which is not removed in the course of the analysis, yields reducing sugar in the final treatment with hydrochloric acid; further, part of the yeast cell membrane is converted by the hot potassium hydroxide into erythrocellulose which behaves like, and in the author's opinion is identical with, yeast glycogen.—L. E.

Ethylmercaptan; Phytochemical formation of ——. C. Neuberg and F. F. Nord. Ber., 1914, **47**, 2264—2271.

When an aqueous alcoholic solution of thialdine (the ammonia-compound of thio-acetaldehyde) was added to an aqueous solution of sucrose undergoing fermentation by means of yeast, no noteworthy slackening of fermentation was observed, and after a few minutes the odour of mercaptan was distinctly perceptible. The formation of ethylmercaptan was demonstrated by passing the fermentation gases through a solution of mercuric cyanide, when a yellow precipitate was produced. This was separated, decomposed with dilute hydrochloric acid, and the evolved gas passed into a solution of lead acetate, a yellow precipitate of the lead salt of ethylmercaptan being produced. In an analogous experiment with dead yeast no formation of mercaptan took place.—A. S.

Acetic fermentation ; Favourable influence of manganese on ——. G. Bertrand and R. Sazerac. Bull. Soc Chim., 1914, **15**, 627—630.

Mycoderma aceti was allowed to act on alcohol in a nutrient medium in presence of varying amounts of manganese sulphate for 2—10 days, and the liquid then titrated with $N/1$ alkali. The quantity of acetic acid formed increased with the proportion of manganese sulphate up to a concentration of about 1 : 10,000, beyond which it decreased. —W. P. S.

PATENTS.

Malting machine. J. Sleeman, Stonehouse, Gloucester Eng. Pat. 13,426, June 10, 1913.

An improved form of the machine described in Eng. Pat. 22,204 of 1911 (this J., 1912, 1091), the perforated hinged sections dividing the space into grain-chamber and air-chamber being dispensed with. The grain lies on a single perforated floor situated midway between the axis and the lower periphery of the drum, so that when the latter is rotated the bed of grain is thoroughly broken up. Air is introduced through a hollow trunnion and distributed by pipes on either side of the floor : gases may be exhausted in a similar manner.—J. F. B.

XIXa.—FOODS.

PATENTS.

Milk ; Apparatus for sterilising, pasteurising, and condensing ——. A. Reynierse, Middelburg, Holland. Eng. Pat. 14,616, June 24, 1913. Under Int. Conv., Jan. 6, 1913.

The milk is introduced into a water-jacketed vessel containing a cooling coil and hollow perforated stirring arms carrying brushes which rub against the wall of the vessel and prevent incrustation. For sterilisation, steam is first admitted to the water-jacket, and when the milk has been heated to about 90° C., steam is admitted through the stirring arms into the milk, the latter being stirred. When the milk has been heated to 120° C., the steam to the arms is cut off, and the water in the jacket is kept at 120° C. for 30 mins. The milk is then cooled, stirring being continued. During sterilisation, air is admitted to the space above the milk, being first sterilised by passage through a sinuous tube.—L. E.

Milk separators ; Centrifugal ——. H. Lanz, Mannheim, Germany. Eng. Pat. 4028, Feb. 16, 1914. Under Int. Conv., May 2, 1913.

Plates fitted in a centrifugal drum are provided with openings for the supply of milk and for conducting the cream to the uptake adjacent to the central inlet ; auxiliary openings in the plates permit the cream to pass radially towards the centre and reduce the surface to which it is exposed.—W. P. S.

Meat and other foodstuffs ; Process for the preservation of ——. O. Bocandé, Paris. Eng. Pat. 19,921, Sept. 3, 1913. Under Int. Conv., Nov. 18, 1912.

Joints of meat are placed in a closed chamber and the air is exhausted from the latter ; air mixed with ozone is then admitted and the chamber again exhausted, a pressure of 5—15 mm. being maintained until the meat has lost from 15 to 20% of its water-content ; the evaporated water is condensed or absorbed by hygroscopic substances. The joints are now removed from the chamber, wrapped in tinfoil, paper, or fabric, and then coated with a mixture consisting of water, 60—65 ; gelatin, 20—25 ; sea salt, 5 ; sugar, 5 ; glycerin, 5 ; and formalin, about 1%. —W. P. S.

Potatoes ; Process for the production of dried ——. C. Warth, Charlottenberg, Germany. Eng. Pat. 3531, Feb. 11, 1914. Under Int. Conv., June 5, 1913.

Potatoes are grated and the mass is washed on a sieve with water to remove the starch. The aqueous portion is centrifuged to separate the water as far as possibl from the starch, and the pulp on the sieve is pressed. The starch and the pulp are then mixed and the mixture dried by heat.—W. P. S.

Food fats ; Manufacture of —— *more particularly for th preparation of pastries and the like.* P. A. Schmitt Hamburg, Germany. U.S. Pat. 1,102,551, July 7, 1914 Date of appl., July 10, 1913.

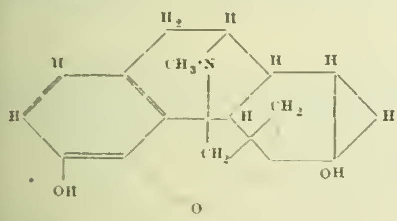
XX.—ORGANIC PRODUCTS ; MEDICINAL SUBSTANCES ; ESSENTIAL OILS.

pium alkaloids. J. v. Braun. Ber., 1914, **47**, 2312—2330.

s the formulæ which have been deduced for morphine, odeine, and thebaine (see Knorr and Hörlein, this J., 907, 943) there is a partially hydrogenised benzene ring ontaining a double linkage in the $\beta\gamma$-position to the itrogen atom. Previous investigations by the author ad indicated that compounds of this character behave bnormally with cyanogen bromide, the ring being ruptured t the nitrogen atom, instead of the normal replacement y a CN-group of a CH_3-group attached to the nitrogen. Then thebaine was treated with cyanogen bromide it was onverted into a compound, soluble in ether, in which the ethyl group attached to nitrogen was still intact. Iorphine and codeine, on the other hand, when treated ith cyanogen bromide, after acetylation of the free ydroxyl groups, behaved in a normal manner, the methyl roup attached to the nitrogen being replaced by a CN-roup, with the production respectively of cyanodiacetylnor-orphine and cyanodiacetylnorcodeine. The acetyl erivatives of dihydromorphine and dihydrocodeine ehaved in a similar manner. It is concluded that in the rmulæ of morphine and codeine there is no double linkage the benzene ring III. (*loc. cit.*), but probably a bridge-nkage connecting the carbon atoms at 6 and 8 :—



n hydrolysis of cyanodiacetyl-normorphine and -nor-deine, the acetyl groups are first removed, and e cyanonormorphine, $C_{16}H_{14}O(OH)_2 : N.CN$, and yanonorcodeine, $C_{16}H_{14}O(OH)(OCH_3) : N.CN$, formed, e subsequently converted respectively into ormorphine, $C_{16}H_{14}O(OH)_2 : NH$, and norcodeine, $_{16}H_{14}O(OH)(OCH_3) : NH$ (Diels and Fischer's N-de-ethylcodeine, this J., 1914, 765). These bases are milar in properties to morphine and codeine (into which ey are converted by methylation), but are more reactive certain directions owing to the presence of the imino-roup. The O-isoamyl derivative of normorphine and the -phenylethyl derivative of norcodeine were prepared. —A. S.

ocaine ; Detection of ——. G. Denigès. Bull. Soc. Pharm. Bordeaux, **52**, 385. Z. anal. Chem., 1914, **53**, 497.

a 0·5% solution of a cocaine salt be treated with an qual volume of a 5% solution of sodium perchlorate, a recipitate composed of long, very fine needles is formed ; ith very small quantities the precipitation is observed nder the microscope.—A. S.

trychnine in presence of brucine ; Determination of ——. D. B. Dott. Proc. Brit. Pharm. Conf., 1914, 8.

HEN strong nitric acid is added in the proportion of 1 vol. 10 vols. of acid solution, and 1 c.c. of nitric acid for ach 0·25 grm. of brucine, a period of 20 mins. at the dinary temperature is sufficient to destroy all the brucine. arming to 40° C. causes an appreciable loss of strychnine. —F. Shdn.

Belladonna leaves ; Adulteration of ——. G. S. Allen and H. Deane. Proc. Brit. Pharm. Conf., 1914, 9—11.

Belladonna is largely adulterated with *Phytolacca decandra*, *Scopola carniolica* and *Ailanthus glandulosa*, which are best distinguished by the microscope. Portions of the leaf are warmed with chloral hydrate solution till sufficiently transparent for microscopic examination. *Phytolacca* shows characteristic acicular raphides of calcium oxalate differing from the sandy crystals of belladonna. In *Ailanthus* and *Scopola* the stomata occur on the lower surface of the leaf whilst in belladonna they are found on both surfaces.—F. Shdn.

Benzoin ; Analytical characters of ——. T. T. Cocking and J. D. Kettle. Proc. Brit. Pharm. Conf., 1914, 13—14.

To determine the balsamic acids in benzoin 5 grms. are extracted with alcohol in a Soxhlet apparatus and the extract hydrolysed with alcoholic potash. The alcohol is evaporated, the residue dissolved in 100 c.c. of water and treated with a slight excess of hydrochloric acid, 5 grms. of light magnesium oxide and 20 c.c. of xylene. The whole is boiled under a reflux condenser for an hour, cooled, the aqueous portion filtered off and the insoluble matter boiled twice with 100 c.c. of water which is allowed to cool before filtering. The combined aqueous extracts are shaken out once with ether, when the balsamic acids are liberated by the addition of hydrochloric acid and removed by ether, the latter being distilled off and the residue dried in a vacuum over sulphuric acid before weighing. To determine the cinnamic acid the ethereal residue is left overnight in contact with excess of a 5% solution of bromine in carbon tetrachloride, and the excess of the latter is driven off by evaporation on the water bath. The residue is evaporated several times with ether, dried as before and weighed. The amount of cinnamic acid is calculated from the increase of weight, one mol. of the acid absorbing 2 atoms of bromine (see this J., 1910, 112). The "free" balsamic acids are determined by boiling the powdered drug with water, magnesium oxide and xylene and proceeding as described above. The acid and ester values are determined on the alcoholic extract of a separate portion of the drug. Analyses of a number of different specimens are given.—F. Shdn.

Pepsin ; Bacteriological purity of ——. E. Quant. Proc. Brit. Pharm. Conf., 1914, 8—9.

Out of eleven samples of pepsin in scale or powder form from various sources, several were contaminated with bacteria. The most satisfactory samples contained a small amount of free acid. The standard might be improved by the presence of free acid and the use of chloroform.—F. Shdn.

Oil rich in sulphur from Kimmeridge shale of St. Champ (France). Demesse and Réaubourg. Bull. Soc. Chim., 1914. **15**, 625—627.

Dry distillation of Kimmeridge shale found at St. Champ yielded an oil of the following composition : C 77·3, H 9·2, S 11·99, N 0·37, O (by diff.) 1·14%. The sulphonation product neutralised by ammonia was similar to ichthyol and like products used in therapeutics.—W. R. S.

Cinnamic aldehyde ; Stability of ——. H. A. Phillips. Proc. Brit. Pharm. Conf., 1914, 17—18.

Cinnamic aldehyde, whether pure or as a constituent of cinnamon oil, is not appreciably oxidised when distilled with steam under ordinary conditions.—F. Shdn.

Carbon bisulphide in official pharmacy and suggestions for its further use. F. H. Alcock. Proc. Brit. Pharm. Conf., 1914, 21—22.

Useful results can be obtained by determining the amounts extracted by carbon bisulphide from official liquid extracts and tinctures. In this way 0·3% of fat, containing very little alkaloid, can be withdrawn from the liquid extract of *Nux vomica*.—F. Shdn.

Glycerophosphates of commerce; Composition of the ——. J. C. Umney and C. T. Bennett. Proc. Brit. Pharm. Conf., 1914, 22—23.

The composition of calcium glycerophosphate varies and does not correspond with a definite molecular proportion of water. The so-called "soluble" salt, containing citric acid, is less likely to cause a deposit in the preparation of the compound syrup. There is no objection to the addition of citric acid so long as the content of calcium is not reduced below 15%. The salt should be soluble in 25 parts of water. Magnesium glycerophosphate may also contain citric acid but the magnesium content should not be less than 10%. Ferric glycerophosphate should contain about 15% Fe and be soluble in 2 parts of water. Solutions of potassium glycerophosphate, which is difficult to obtain in crystalline form, should be required to contain definite percentages of the anhydrous salt. Sodium glycerophosphate crystallises with 5 mols. H_2O.—F. Shdn.

Cadmium salicylate. W. O. de Coninck. Bull. Soc. Chim., 1914, **15**, 608—609.

Freshly precipitated cadmium carbonate is treated with warm aqueous salicylic acid solution containing a little alcohol, and the salt re-crystallised from boiling water, from which it is deposited without decomposition. The salt, dried at 95°—96° C., has the composition, $[C_6H_4(OH).CO.O]_2Cd + H_2O$; it does not decompose below 165° C., when it gives off carbon dioxide and phenol; it chars above 170° C.—W. R. S.

Determination of rhamnose in presence of other methylpentoses. Votocek and Potmesil. *See* XXIII.

Patents.

Hydrogenised organic substances or compounds [of the opium group]; Manufacture of ——. Verein Chininfabriken Zimmer und Co., G. m. b. H., Frankfort, Germany. Eng. Pat. 14,247, June 19, 1913. Addition to Eng. Pat. 10,204 of 1913, dated May 9, 1912 (see this J., 1913, 989).

Morphine, codeine, and other opium compounds are hydrogenated by treating them with formic acid and a finely divided metal of the platinum group, or a colloidal solution of such metal. For example, 5 parts of codeine hydrochloride are dissolved in 70 parts of a 1% solution of formic acid and mixed with the palladium black obtained from 0·5 part of palladious chloride. The solution is allowed to stand first at the ordinary temperature for a few hours and then at 50° C. until evolution of carbon dioxide has ceased; it is then filtered, mixed with excess of soda lye, saturated with common salt, and extracted with ether The ethereal extract contains the hydrocodeine, which can be recrystallised from water.—T. F. B.

Acetylation [of halogen-hydrocarbons]; Process of ——. W. E. Masland, Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,095,013, April 28, 1914. Date of appl., Oct. 16, 1912.

A mixture of halogen derivatives of aliphatic hydrocarbons (*e.g.*, amyl and hexyl chlorides) is acetylated at a temperature suitable for removing halogen acid from them, with the formation of olefines; the olefines are removed and the remaining chlorohydrocarbons are acetylated at temperatures suitable for the formation of organic acetates (compare Eng. Pat. 29,963 of 1912; this J., 1914, 502).—T. F. B.

Dichlorohydrocarbons; Acetylation of ——. W. E. Masland, Assignor to E. I. du Pont de Nemours Powder Co., Wilmington, Del. U.S. Pat. 1,102,347, July 7, 1914. Date of appl., Oct. 19, 1912.

Dichlorohydrocarbons, such as mixtures of dichloropentane and dichlorohexane, are acetylated by treatment with 70 to 99% acetic acid in presence of sodium acetate. —T. F. B.

Oxidising compounds and producing terpene peroxide; Process of ——. A. S. Ramage, Detroit, Assignor to E. A. Byrnes and C. P. Townsend, Washington. U.S. Pat. 1,097,939, May 26, 1914. Date of appl., March 6, 1906.

The vapours of terpenes and other oxidisable liquids are passed over a catalytic agent, such as platinised asbestos, and simultaneously treated with ozone. Terpenes are converted into peroxides by this process.—T. F. B.

Organic peroxide [from cineol] and process of producing same. A. S. Ramage, Detroit, Assignor to E. A. Byrnes and C. P. Townsend, Washington. U.S. Pat. 1,097,940, May 26, 1914. Date of appl., March 31, 1906.

Cineol is subjected to the continued action of ozone in presence of a catalytic agent (*e.g.*, platinum black) at the ordinary temperature, until a thick, viscous, non-volatile liquid is obtained. This liquid is brownish-yellow, insoluble in water, soluble in petroleum; it is an active oxidising agent and germicide, liberating iodine from potassium iodide, and containing about 18 times its volume of loosely-combined oxygen; it decomposes explosively when heated.—T. F. B.

Terpene peroxide; Process of producing ——. A. S. Ramage, Cleveland, Assignor to E. A. Byrnes and C. P. Townsend, Washington. U.S. Pat. 1,098,356, May 26, 1914. Date of appl., Feb. 7, 1903.

Terpenes capable of being oxidised to peroxide, are treated with ozone or ozonised air at a temperature above 38° C., and in absence of water, the reaction being carried out under conditions to "drive off the terpene peroxide in the form of fumes."—T. F. B.

Quinoline compounds and process of producing same. A. B. Davis, Assignor to Eli Lilly and Co., Indianapolis. U.S. Pat. 1,098,022, May 26, 1914. Date of appl., Jan. 31, 1913.

Equimolecular proportions of salicylic aldehyde, pyruvi acid, and a suitable aromatic amine (*e.g.*, *p*-toluidine) ar boiled together in absolute alcoholic solution, and th product is allowed to crystallise. 2-*o*-Hydroxyphenyl-6 methylquinoline-4-carboxylic acid is produced when *p* toluidine is used.—T. F. B.

Formaldehyde; Process of making ——. H. von Hoch stetter, Constance, Germany. U.S. Pat. 1,100,076, Jun 16, 1914; date of appl., Jan. 9, 1913.

Formaldehyde is produced by passing a mixture of ai and methyl alcohol vapour at a suitable temperatur over two or more catalysts, *e.g.*, through a copper tub containing metallic silver, which may be precipitated upo the copper.—H. H.

Gallic acid; Preparation of ——. M. Hamel, Assign to Nitritfabrik Akt.-Ges., Berlin. U.S. Pat. 1,100,73 June 23, 1914; date of appl., Feb. 25, 1914.

Moist fermented masses of nutgalls, sumac and the like ar dried at an elevated temperature in order to convert th impurities formed during the fermentation into a stat in which they are insoluble in the solvents used for subs quently extracting the gallic acid.—D. J. L.

Chloroform; Method of making ——. T. Griswold, jun and C. J. Strosacker, Assignors to The Midland Chemic Co., Midland, Mich. U.S. Pat. 1,101,025, June 23, 191 Date of appl., July 26, 1912.

Carbon tetrachloride is reduced in presence of water l a metal, such as iron, a portion of which, at least, introduced in the form of relatively coarse particles, whi are subjected to a grinding action to reduce them to fin particles.—T. F. B.

Alkyl sulphates; Process for the manufacture of alipha ——. E. Wolf, Assignor to Chinoin gyógyszer és ve yészeti termékek gyára r. t. Dr. Kereszty és Dr. Wo Ujpest, Austria-Hungary. U.S. Pat. 1,101,373, June 1914. Date of appl., Dec. 8, 1913.

Aliphatic simple or mixed ethers are converted into t corresponding alkyl sulphates by adding sulphuric a chlorhydrin at a low temperature and heating the mixture until the evolution of hydrogen chloride ceases.—T. F. B.

Essential oils, perfumes, and odorous substances ; Process for extracting ——. J. A. Meunier. First Addition, dated Aug. 18, 1913, to Fr. Pat. 466,273, Feb. 26, 1913 (see this J., 1914, 613).

The aqueous solutions or mixtures containing the odorous products, obtained as described in the principal patent, are concentrated by distillation. This is necessary to ensure the production of stable extracts, particularly in the case of fruits.—T. F. B.

Methyl-hexamethylenetetramine thiocyanate ; Process for making ——. K. H. Schmitz. First Addition, dated Dec. 31, 1913, to Fr. Pat. 466,619, Dec. 26, 1913.

See Ger. Pat. 270,486 of 1913 ; this J., 1914, 439. The perchlorate, chromate, and other salts can be obtained n a similar manner to the thiocyanate. The free base, $C_6H_{12}N_4(CH_3)OH$, is obtained by treating the chromate with barium oxide or the halides with moist silver oxide ; by neutralising this with the appropriate acid, pure salts are obtained.—T. F. B.

Esters of tertiary alcohols ; Process for preparing ——. Dr. Neumann und Co. Chem. Fabrik G. m. b. H., and J. Zeltner. Fr. Pat. 466,804, Nov. 8, 1913.

Tertiary alcohols are esterified by treating them with acid chlorides in presence of tertiary bases, such as pyridine r dimethylaniline. In some cases the reaction is facilitated by gentle heating.—T. F. B.

Dimethyl-p-aminophenol and p-hydroxyphenyltrimethylammonium ; Process for preparing pure, stable salts of ——. Fabrique de Produits Chimique ci-dev. Sandoz. Fr. Pat. 467,085, Jan. 7, 1914. Under Int. Conv., Nov. 18, 1913.

The product obtained by the methylation of *p*-aminohenol contains the mono- and dimethylaminophenols ogether with a salt of *p*-hydroxyphenyltrimethylammonium. To separate these, advantage is taken of the act that *p*-aminophenol and its monomethyl derivative o not form precipitates with ferrocyanides in acid soluion, whilst the other two compounds are precipitated apidly and completely as acid ferrocyanides : these two ompounds can then be separated from one another by crystallisation in presence of a normal alkali sulphite, hen dimethyl-*p*-aminophenol is separated in the form f a normal ferrocyanide and the quaternary ammonium ompound remains in solution. A separation of the bases om their mixed ferrocyanides can also be effected by aking the mixture feebly alkaline and extracting the imethyl-*p*-aminophenol by means of benzene or other olvent.—T. F. B.

3-Dihalogen-2-methylbutane and homologues thereof ; Producing ——. O. Graul, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 1,102,654, July 7, 1914. Date of appl., Sept. 5, 1912.

ee Eng. Pat. 3870 of 1912 ; this J., 1913, 252.—T. F. B.

o-olefines ; Producing ——. O. Graul, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 1,102,655, July 7, 1914. Date of appl., March 13, 1913.

ee Fr. Pat. 450,461 of 1912 ; this J., 1913, 624.—T. F. B.

ethyl-hexamethylenetetramine thiocyanate ; Process for making ——. K. H. Schmitz. Fr. Pat. 466,619, Dec. 26, 1913. Under Int. Conv., Feb. 3, 1913.

ee Ger. Pat. 266,788 of 1913 ; this J., 1914, 43.—T. F. B.

ormaldehyde : Process for making ——. Holzverkohlungs-Industrie Akt.-Ges. Fr. Pat. 467,076, Jan. 7, 1914. Under Int. Conv., Jan. 9, 1913.

e U.S. Pat. 1,100,076 of 1914 ; preceding.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Patents.

Silver gelatinobromide or collodio-bromide paper with two emulsions for rapidly producing direct positives in the camera. A. Balconi. Fr. Pat. 466,996, Jan. 5, 1914.

Paper is coated with a slow (*e.g.*, gas-light) emulsion, then with a layer of arrowroot or other starch paste, and finally with a rapid emulsion. After exposure in the camera and development, the paper is exposed to light, the negative film is stripped off, and the positive developed on the slow emulsion. This produces reversed positives. If it is desired to make correct positives, the emulsions are applied to opposite sides of a thin, grainless paper.—T. F. B.

Polychrome screen plates for colour photography ; Manufacture of ——. A. and L. Lumière. Fr. Pat. 467,128, March 21, 1913.

One of the difficulties in preparing polychrome screen-plates is due to the screen presenting a certain amount of colour, which affects the general tone of the finished photographs. It has not been found possible to correct this by staining the gelatin emulsion, but satisfactory results have been obtained by the use of a layer of varnish of a colour complementary to that of the fault in the screen ; the varnish may be introduced between the screen and the emulsion or it may be applied to the glass.—T. F. B.

Colour photographs and the process for their production. A. H. Walker, London. From The Hess-Ives Co., Philadelphia. Eng. Pat. 15,823, July 9, 1913.

See Fr. Pat. 463,737 of 1913 ; this J., 1914, 441.—T. F. B.

Photographic plates, films, and papers ; Sensitive ——. R. E. Crowther. Fr. Pat. 466,530, Dec. 24, 1913. Under Int. Conv., Dec. 30, 1912.

See Eng. Pat. 29,919 of 1912 ; this J., 1914, 221.—T. F. B.

Bleaching-out layers for colour photography ; Process for producing —— *either ready sensitised or to be sensitised before use.* J. Szczepanik and F. Habrich. Fr. Pat. 466,906, Sept. 8, 1913. Under Int. Conv., Sept. 9, 1912.

See Ger. Pat. 264,207 of 1912 ; this J., 1913, 1033.—T. F. B.

Preparing pure stable salts of dimethyl-p-aminophenol and p-hydroxyphenyltrimethylammonium. Fr. Pat. 467,085. *See* XX.

XXII.—EXPLOSIVES ; MATCHES.

Patents.

Detonating explosive charges for mining and military purposes ; Method of ——. C. Claessen, Berlin. Eng. Pat. 16,456, July 17, 1913.

See Addition of July 7, 1913, to Fr. Pat. 459,979 of 1913 ; this J., 1914, 44.—T. F. B.

Explosive. O. Silberrad, Buckhurst Hill. U.S. Pat. 1,102,964, July 7, 1914. Date of appl., Nov. 23, 1912.

See Eng. Pat. 13,860 of 1911 ; this J., 1912, 1009.—T. F. B.

Reaction-vessel for carrying out chemical processes of all kinds between two or more liquids, solutions, solids in paste form, and also gases. Ger. Pat. 274,854. *See* I.

XXIII.—ANALYTICAL PROCESSES.

Iron in the presence of phosphoric acid ; Determination of ——. C. E. Corfield and W. R. Pratt. Proc. Brit. Pharm. Conf., 1914, 19—21.

Gravimetric determinations of iron are unreliable in the presence of even small quantities of phosphoric acid.

Ferrous iron can be oxidised by boiling with hydrogen peroxide and the ferric iron determined by the usual iodimetric method, care being taken that the hydrochloric acid is in excess. Satisfactory results are obtained by reduction with stannous chloride.—F. Shdn.

Rhamnose; Determination of —— in presence of other methylpentoses. E. Votoček and R. Potmesil. Bull. Soc. Chim., 1914, **15**, 634—639.

Hydrocyanic acid converts rhamnose into a cyanhydrin which, on hydrolysis, gives α-rhamnohexonic acid, nitric acid (sp. gr. 1·15—1·2) oxidising the latter to mucic acid. After oxidation is complete, the liquid is evaporated to one-third of its bulk on a water-bath and left to stand for 3 days in the cold, while occasionally rubbing the sides of the beaker with a glass rod. The crystalline precipitate of mucic acid is washed with a little cold water, dried and weighed. 100 parts of anhydrous rhamnose gave an average of 45·5 parts of mucic acid. In presence of other methylpentoses (*e.g.*, rhodeose) the yield of mucic acid was not quite so constant, but sufficiently so to determine the molecular proportion of rhamnose in the products of hydrolysis of glucosides containing it.—W. R. S.

Modification of the Jaeger method for determining hydrogen and methane. Wibaut. *See* IIa.

Effect of acidity of assay slags on silver losses. Livingstone. *See* X.

Patents.

Detecting combustible or explosive gases, especially fire-damp; Device for ——. Accumulatoren-Fabrik A.-G. and F. Rüsse, Berlin, Germany. Eng. Pat. 15,064, June 30, 1913.

A safety-lamp and spark gap are supplied from the same source of current through separate circuits controlled by a change-over switch, the spark gap being connected with the secondary winding of an induction coil. The device may be made more sensitive by employing an electrically-heated wire below the spark gap, the latter being placed within the constricted portion of a glass tube; the gas to be tested is thus heated and its velocity increased.—B. N.

Lubricants; Apparatus for testing ——. R. Drosten. Ger. Pat. 275,225, June 7, 1913. Under Int. Conv., June 22, 1912.

The apparatus is of the type in which a mixture of steam and oil is subjected to friction between a fixed and a rotating surface in a closed casing. In the apparatus described, a vertical rotating shaft carries at different heights two conical valves which rotate on seatings; the latter are provided with openings under control. The oil is delivered on to the upper end of the shaft and the steam is delivered above the upper valve. The space between the two valves acts as a steam-expansion chamber. The oil finds its way between the valves and their seatings and passes through the openings in the latter along with the steam. The mixture of steam and oil leaving the chamber is passed to a condenser.—A. S.

Pyrometers. J. Churchward, Mount Vernon, N.Y., U.S.A. Eng. Pat. 15,922, July 10, 1913.

See U.S. Pat. 1,069,318 of 1913; this J., 1913, 928.—T. F. B.

Trade Report.

Withdrawal of prohibition of certain exports from the United Kingdom.

A supplement to the "London Gazette," dated August 20th, 1914, contains a Proclamation modifying the Proclamations of August 3rd, 5th, and 10th, relative to the prohibition of certain exports from the United Kingdom.

The list published in this Journal, August 15th, 1914, page 810, is accordingly modified as follows:—

The Ports of Belgium are added to the list of Ports excepted from the prohibition.

The following articles are deleted from the list:—Coal, steam, large; fuel, manufactured; nitrates of sodium; tin plates; creosote; glucose.

"Lead, pig, sheet or pipe" is inserted in place of "Lead in all forms."

Union of South Africa; New Customs Tariff and Regulations of the ——, 1914. Suppl. to the Board of Trade J., Aug. 13, 1914. Price 3d.

Among the changes in and additions to Class I. (special rates) of this tariff are the following:—

33. Motor spirit, namely benzine, benzoline, naphtha (not potable), gasoline, petrol, and petroleum spirit generally. 2d. per impl. gallon.

34. Lubricating oils (not elsewhere specified), 3d. pe impl. gallon.

45c. Saccharin, now includes derivatives of ortho toluenesulphamide, dulcin and derivatives of phenylcarbamide and other sweetening substances, £1 per lb.

48. Varnish. 2s. per impl. gallon.

Class III. (25% *ad valorem*) now includes glycerin distilled, not in bulk (formerly 15% *ad val.*). Class IV (3% *ad. val.*) includes glycerin other than crude, and i bulk for manufacturing purposes. Class V. (free of duty includes the items glycerin, crude, in bulk (formerly 15 *ad. val.*); dyes for manufacturing purposes, and tannin substances for leather, including alum; radium; sulphu and iron pyrites in bulk; tallow, including vegetabl tallow.

Netherlands; Prohibition of certain exports from the —— Board of Trade, Aug., 1914.

The issues of the "Nederlandsche Staatscourant" f the 1st, 3rd, and 8th August publish Decrees prohibitin the exportation of the undermentioned articles from th Netherlands:—Acetone; ammunition and gunpowder coal and coke; ether; gold coin and material for mintir gold (except in special cases in which exemption from th prohibition may be allowed); glycerin; lead; medicin bandages, and materials for making the same; molasse sodium nitrate; sugar.

Books Received.

Alkali, etc., Works Regulation Act, 1906. Fiftie Annual Report on Alkali, etc. Works, by the Chi Inspector. Proceedings during the year 1913, H.C. 3 Wyman and Sons, Fetter Lane, E.C. Price 7½d.

A full abstract of this report will appear in an early iss of the Journal.

Some Engineering Phases of Pittsburgh's Smo Problem. Bulletin No. 8 of "Smoke Investigatio Mellon Inst. of Industrial Research, Pittsburgh, P U.S.A. 193 pp. 8vo.

Journal of the Society of Chemical Industry.

No. 17, Vol. XXXIII. SEPTEMBER 15, 1914. No. 17, Vol. XXXIII.

Official Notices.

INTERNATIONAL CONGRESS OF MINING, METALLURGY, &c., LONDON, 1915.

At a meeting of the Executive Committee of the Congress, held at the Iron and Steel Institute on September lth, it was decided, owing to the War, to adjourn *sine die* he holding of the Congress, and, subject to a small levy or expenses already incurred, to release the guarantors rom any further liability.

'OMPETITION WITH GERMANY AND AUSTRIA-HUNGARY.

Further Action by the Board of Trade.

The Board of Trade have received many inquiries for ames of sellers or buyers of articles of which sources of ipply or markets have been interfered with by the war, nd special arrangements have been made for dealing with iem. Lists are being prepared and circulated of articles hich inquirers desire (a) to purchase and (b) to sell. The rst lists (see page 896) may be obtained on application to ie Commercial Intelligence Branch. Firms interested in ay of the goods mentioned, either as buyers or sellers, iould communicate with the Director. An enlarged mple room will also be established exclusively for exbiting samples of German and Austrian or Hungarian oods or materials which have competed with British oducts at home or abroad, especially those which are cessary for the continuance of British manufacture it which cannot be obtained from their previous sources. rms who may wish to exhibit goods are invited to apply the Commercial Intelligence Branch.

A catalogue library will also be opened, and firms are vited to furnish catalogues of goods formerly received by em from Germany and Austria-Hungary; these catagues will be classified by trades in order to be readily cessible to inquirers.

The address of the Commercial Intelligence Branch is , Basinghall Street, London, E.C.

'ATENTS, DESIGNS, AND TRADE MARKS TEMPORARY RULES (AMENDMENT) ACT, 1914.

4 & 5 Geo. 5. Chap. 73.

An Act to amend the Patents, Designs, and Trade arks (Temporary Rules) Act, 1914.

28th August, 1914.

Be it enacted by the King's most Excellent Majesty, and with the advice and consent of the Lords Spiritual d Temporal, and Commons, in this present Parliament sembled, and by the authority of the same, as follows :—

1. The Patents, Designs, and Trade Marks (Temporary les) Act, 1914, shall have effect, and shall be deemed ays to have had effect, subject to the following amendnts, that is to say :—

(a) In section one, for the words "any patent or licence granted to, and the registration of any trade mark the proprietor whereof is, a subject of any State at war with His Majesty, and any proceedings on any application made by any such person under either of the said Acts," there shall be substituted the following words: "any patent or licence the person ntitled to the benefit of which is the subject of any State at war with His Majesty; for avoiding r suspending the registration, and all or any rights conferred by the registration, of any design or trade mark the proprietor whereof is a subject as aforesaid: for avoiding or suspending any application made by any such person under either of the said Acts; for enabling the Board to grant, in favour of persons other than such persons as aforesaid, on such terms and conditions, and either for the whole term of the patent or registration or for such less period, as the Board may think fit, licences to make, use, exercise, or vend patented inventions and registered designs so liable to avoidance or suspension as aforesaid":

(*b*) At the end of the same section the following subsection shall be added :—

"(4) This Act shall apply to any person resident and carrying on business in the territory of a State at war with His Majesty as if he was a subject of that State; and the expression 'subject of any State at war with His Majesty' shall, with reference to a company, include any company the business whereof is managed or controlled by such subjects, or is carried on wholly or mainly for the benefit or on behalf of such subjects, notwithstanding that the company may be registered within His Majesty's dominions: and, where a patent has been granted to any person in respect of an invention declared in the application or any specification to have been communicated to him by some other person, that other person shall, for the purposes of this Act, be deemed to be the person entitled to the benefit of the patent unless the contrary is proved."

2. This Act may be cited as the Patents, Designs, and Trade Marks Temporary Rules (Amendment) Act, 1914; and the Patents, Designs, and Trade Marks (Temporary Rules) Act, 1914, and this Act may be cited as the Patents, Designs, and Trade Marks (Temporary Rules) Acts, 1914.

PATENTS AND DESIGNS (TEMPORARY) RULES, 1914.

Dated September 7, 1914.

Statutory Rules and Orders, 1914. *No.* 1328.

By virtue of the provisions of the Patents, Designs and Trade Marks (Temporary) Rules Acts, 1914, the Board of Trade do hereby make the following Rules :—

1. In any case in which the Board of Trade make an Order by virtue of the powers vested in them under the provisions of the Patents, Designs, and Trade Marks (Temporary) Rules Acts, 1914, and under any Rules made under these Acts or either of them, avoiding or suspending in whole or in part a Patent, or avoiding or suspending the registration and all or any rights conferred by the registration of any Design the Board may in their discretion grant in favour of persons other than the subject of any State at war with His Majesty, licences to make, use, exercise, or vend the patented invention or registered design so avoided or suspended upon such terms and conditions, and either for the whole term of the patent or registration of the design, or for such less period as the Board of Trade may think fit.

2. These Rules shall be read and construed as one with the Patents, Designs, and Trade Marks (Temporary) Rules, 1914, dated 21st August, 1914, and the Designs Rules, 1914, dated 5th September, 1914.

London Section.

NOTES ON THE APPLICATION OF TUNGSTEN SALTS TO THE ANALYSIS OF TANNING MATERIALS.

BY ALEXANDER T. HOUGH.

Whilst investigating the properties of colloidal tungstic acid from quite another point of view, its suitability for the differential analysis of tanning materials became apparent, inasmuch as it gives a reaction with the tannins, analogous to that discovered by Lauffmann with ammonium molybdate (Collegium, 1913, No. 513, p. 10; this J., 1913, 153).

I have been able to prepare two reagents with sodium tungstate, which apparently give different results with the same tannin. The importance of this lies in the fact that it may be possible to establish the purity of a given tanning extract by the constancy of the ratio between the two results given by the different reagents.

Unfortunately, it has only been possible to carry out experiments with mangrove extract, in the manufacture of which I am at present engaged; I am therefore unable to state whether this ratio between the two results will be the same for other tanning materials or not; in the affirmative it naturally loses its importance, as to be interesting it should furnish a characteristic number for each material.

Then, again, the acidity of an extract may have some bearing upon the results, but unless it is such as to more than neutralise the sodium ion of the tungstate—and this is barely possible—I do not anticipate any exaggerated divergence from this source. In any case, even though the ratio of the two figures should prove to be unimportant, the figures themselves will be characteristic of each tanning material in the same way as the "molybdate figure" of Lauffmann.

The following table gives the composition of the two reagents I have worked with:—

Table I.

	Reagent 1.	Reagent 2.
	c.c.	c.c.
10% sodium tungstate	5	5
25% ammonium chloride	3	3
8% by volume HCl	—	2
Water	2	—

In both cases the ammonium chloride solution should be added last and the reagents should only be mixed immediately before use, as after a short interval they rapidly deposit crystalline tungstic acid. The 8% solution of hydrochloric acid was 0·85 normal, *i.e.*, 2 c.c. hydrochloric acid neutralised 17 c.c. *N*/10 sodium carbonate or 5 c.c. of a 10% solution of sodium tungstate, freeing the tungstic acid in the colloidal state; the resulting solution did not turn methyl orange red but was slightly acid to litmus.

In using these solutions for the analysis of tanning materials, the method of Lauffmann is followed exactly, of which the following is a résumé:—

A tannin solution is prepared containing about 4 grms. tannin in 250 c.c. and 10 c.c. of the filtered solution is mixed with 10 c.c. of the reagent; the whole is filtered and 10 c.c. of the filtrate is evaporated to dryness—(A). The precipitate on the filter is now dissolved in hot water, added to the remainder of the filtrate and the washings of both pipette and beaker, then evaporated to dryness—(B). Both residues are dried until constant in weight and the weight of the precipitate is B—A. It is necessary to determine the salted-out tungsten-tannin precipitate by this indirect method as it cannot be washed.

The amount of precipitate is now calculated on the percentage of tanning matter in the extract, and to do this the total solubles in 10 c.c. of the above tannin solution are determined and the amount of tannin in this solution—(C) calculated from the non-tan figure obtained by the official method of tannin analysis using the above solution diluted four times. Then $\frac{(B-A)\,100}{C}$ gives the "Tungstate figure" of the tannin using the first reagent, and the same formula gives the "Tungstic figure" of the tannin using the second reagent, and presumably $\frac{\text{Tungstic}}{\text{Tungstate}} = K$ for any given tanning material.

The following table shows the results obtained with pure mangrove extract "Tannadine," but I cannot vouch for their absolute accuracy, as climatic and other conditions tend to make exact research a difficult matter in Borneo.

Table II.

		Reagent 1.	Reagent 2.
A.	Solids in 10 c.c. of filtrate	0·560 grm.	0·597 grm.
B.	Solids in remainder	0·755 grm.	0·802 grm.

	Ratio	1·0503	
	Solubles in 10 c.c. tannin solution	0 178 grm.	
C.	Tannin „ „ „	0·131 grm.	

It will be noticed that with reagent 1 the solids a much lower than with reagent 2; this is due to the stro alkaline reaction of sodium tungstate which decompos the ammonium chloride. With reagent 2 the added ac naturally fixes the ammonia although a small amount still released during evaporation.

The filtrate from reagent 1 is pale red; this is probab due to the action of the atmospheric oxygen on the tanni like matters in the alkaline filtrate. The filtrate from agent 2 is of a pale straw colour, but upon the addition alkali gradually develops a reddish tint. The precipita from the latter is also lighter in colour and more eas soluble in water.

I regret my inability to follow up this work here, a request my interested colleagues to apply the reacti to and establish the constants of other tanning materi

Finally I have to thank the Chemische Fabrik v Heyden, Radebeul, for kindly sending me samples sodium tungstate.

Pontianak, Borneo, May, 1914

Journal and Patent Literature.

Patent Specifications may be obtained by post by remitting as follows:—

English.—8*d.* each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery L London, W.C.

United States.—1*s.* each, to the Secretary of the Society.

French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue des Francs Bourg Paris (3e.); Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.

German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, Germany.

I.—GENERAL PLANT; MACHINERY.

Filtration; Studies on ——. J. W. Bain and A. E. Wigle. J. Ind. Eng. Chem., 1914, 6, 672—675.

To determine the amount of liquid retained by a mass of finely-divided solid when filtration is carried out under atmospheric or other pressure, or by centrifuging, experiments were made with well-rounded lake sand graded into various sizes (30-, 40-, 50-, 60-, and 80-mesh) by screening: the 40-mesh size, *e.g.*, being composed of grains which passed a 30-mesh but were retained a 40-mesh screen. It was found that the pore space is practically independent of the size of grain, ranging f m 34·1 to 37·7% of the total volume, and a mass of m d small and large grains was similar in porosity to ma es of either small or large grains alone. For masse of crystals such as are commonly produced by rapid coo g, the pore space may be taken as approximately of the total volume. Experiments made by King (Nineteenth Ann. Report, U.S. Geol. Survey) showed that at atmospheric pressure, sand of 20-mesh size retained 11%, and sand of 100-mesh size 20% of water, after draining for 1 hour. In the authors' tests, using a vacuum of 2 ins. of mercury for 15 mins., the amount of water retained, ranged from 5·7 to 7·5%, average 7%, for sand of from 30- to 80-mesh size. In a layer of sand 70 cm. leep, using a vacuum of 5 ins. of mercury for 15 mins., he water retained was, on the average, 4% in the top 10 cm.) and 6·5% in the bottom layer, the size of grain eing of little importance. By the use of a centrifuge, t was possible to reduce the water-content to about 3·5%, irrespective of the size of grain. It was calculated hat in the case of sand of 30-mesh size retaining 6% of moisture, each grain would have a film 0·0116 mm. thick f all the water were distributed over the surface of the particles; or the water would occupy 30% of the pore pace. (See also Hatschek, this J., 1908, 538.)—A. S.

PATENTS.

Drying machines; Steam-heated cylinders of ——. T. Garstang and J. Kershaw, Blackburn, and J. Gent, Chorley. Eng. Pat. 14,545, June 24, 1913.

THE "dolly-head" or bearing for the journal-pin of a team-heated cylinder is provided with a ball or roller earing situated in front of the inner face of the ordinary earing and separated therefrom by an oil well or grease up to prevent any steam which may leak past the ordinary earing, from gaining access to the ball or roller bearing. —W. H. C.

ryer. W. B. Ruggles, Bayonne, N.J. U.S. Pat. 1,105,927, Aug. 4, 1914. Date of appl., June 11, 1909.

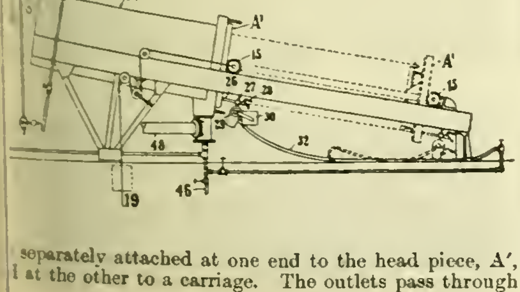
EE Eng. Pat. 10,349 of 1910; this J., 1911, 672.—T. F. B.

rying pulpy materials; Machine for ——. J. T. Knowles, London. From The Sherwin-Williams Co., Cleveland, Ohio, U.S.A. Eng. Pat. 19,409, Aug. 27, 1913.

HE pulp is fed on to an annular rotary drying table, vided into sections which are heated independently. he vapours are drawn off through hoods arranged over e sections and the dried material is stripped from the nnular table by a scraper placed behind the feed point d discharged over the inner edge of the table into a pper. Dust carried by the air current is removed by dust-filter. The whole apparatus is enclosed in a casing d a slightly reduced pressure is maintained therein. prevent the leakage or dust or poisonous gases.—W. H. C.

ltering apparatus. A. L. Genter, Charlottenburg, Germany. Eng. Pat. 14,592, June 24, 1913.

ONGITUDINAL filter-frames covered with bags of filter-th and having their upper edges protected by a metal p to prevent the formation of filter-cake on the top,



separately attached at one end to the head piece, A′, d at the other to a carriage. The outlets pass through the headpiece and can be separately controlled. The carriage is supported on wheels, 15, running on rails, and counterbalanced by weights attached to cords, 19, so that it can be easily run into or out of the inclined chamber, A. The end piece, A′, is made tight by a system of radial toggles and levers and the liquid to be filtered is pumped through the main, 46, the filtrate escaping by the pipes and taps, 26, 27, 28, either into the closed conduit, 29, or the trough, 30. When the cakes are of sufficient thickness the carriage is run out of the chamber and any pieces of cake or sand that may have collected on the bottom of the chamber are pushed out by a hemispherical scraper attached to the rear of the carriage. Compressed air or steam is admitted to the interior of the filter-frames along with an injected cleansing agent and the cakes are stripped off. The carriage is then run into the chamber again and the filter-cloths may be further cleansed by pumping water into the chamber through the pipe, 48, and injecting air at the same time to agitate the water. To prevent the premature discharge of the cakes when the excess of liquid is withdrawn, a float chamber, 41, and a reducing valve, 38, are provided, which admit low-pressure air as the liquid is discharged, so that there is always a slight pressure within the chamber.—W. H. C.

Dryer. J. Janka and O. Vyskŏcil. Fr. Pat. 466,568, Nov. 22, 1913. Under Int. Conv., Nov. 23, 1912.

THE passage of air into and out of the dryer, inside which a separate circulation of air is maintained, is regulated by dampers controlled electrically or pneumatically by a hygrometer within the dryer.—O. E. M.

Filters; Mechanical ——. The Pulsometer Engineering Co., Ltd., and J. Björnstad, Reading. Eng. Pat. 20,652, Sept. 12, 1913.

IN mechanical filters which are cleaned by reversing the flow, in order to secure the cleansing of the filter material which lies next the shell, an enlarged recessed ring is formed in the shell to support the strainer plates.—W. H. C.

Filters; Process and apparatus for the preparation of a refractory material with large pores for —— *and for other applications.* L. Kern. Fr. Pats. 466,657 and 466,659, Dec. 26, 1913. Under Int. Conv., Sept. 19 and Dec. 3, 1913.

A MIXTURE of refractory material with organic substances and a binding agent is heated in a furnace and oxygen from an independent source forced through the pores to burn out the organic matter; or, after heating, high-pressure air is forced through the material for the same purpose, after which the calcination is completed in a still atmosphere.—W. H. C.

Retort or furnace tubes or chambers for gaseous reactions at high temperatures; Manufacture of ——. R. P. Pictet, Berlin. Eng. Pat. 15,379, July 3, 1913.

To prepare tubes which will be impermeable to hydrogen and which will not suffer deformation when heated to 2000° C., a paste is made of highly refractory oxides and mixed with finely-divided carbon prepared by decomposing hydrocarbons by heat. After the tubes have been formed and dried they are heated to incipient fusion either electrically or in a reverberatory furnace heated by water gas and oxygenated air.—W. H. C.

Hollow vessel for chemical reactions. R. Glauser. Fr. Pat. 467,796, Jan. 28, 1914. Under Int. Conv., Jan. 29, 1913.

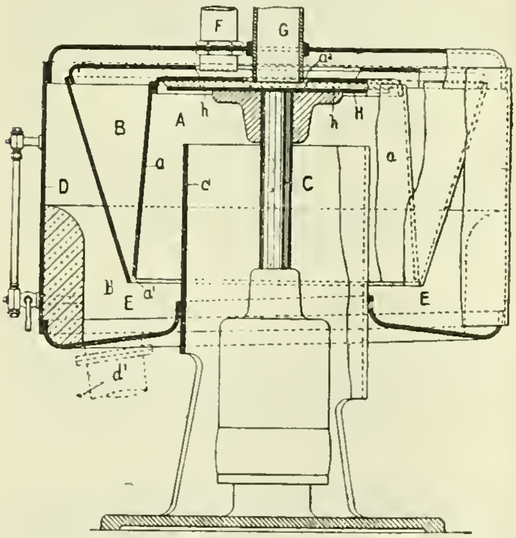
THAT part of the hollow vessel which comes into contact with the chemicals is formed of glass, porcelain or other refractory material which is a poor conductor of heat, and that portion which comes into contact with the fire is provided with a coating of a suitable metal which is a good conductor.—W. H. C.

Gas-furnaces ; Regenerative ——. F. K. Siemens. First Addition, dated Jan. 9, 1914 (under Int. Conv., Dec. 5, 1913), to Fr. Pat. 461,938, Aug. 27, 1913 (this J., 1914, 342).

The air and gas passages are so connected that the major portion of the preheated air is employed for the direct flame heating the sole or hearth of the furnace and a smaller proportion for a flame which serves to heat the regenerators.—W. H. C.

Separating [*solid*] *materials by centrifugal force ; Process and apparatus for* ——. W. W. Richardson, St. Austell, Cornwall. Eng. Pat. 26,142, Nov. 14, 1913.

Two vessels, A and B, of the shape shown (see fig.), are rotated about a common axis, C, within an outer casing, D. Water is fed through the pipe, F, on to the top of the vessel, A, and flows down over its outer surface, part being caused by the centrifugal force to stand up against the inner surface of the outer vessel, B, in a line vertically above the lip, *b′*, and part escaping between the edges, *a′*, *b′*. The latter portion fills the space, E, to a predetermined level, sealing the lower ends of the vessels, A, B. The solid material to be separated is fed through the pipe, G, on to the plate, H, is distributed by the vanes, *h*, and along with some of the water flows down the inner surface, *a*, of the vessel, A. When it reaches the lower edge, *a′*, which is slightly overlapped by the edge, *b′*, the heavier particles are projected through the water on to the edge, *b′*, and are caused by the centrifugal action to rise and collect in the upper part of B. The lighter particles pass on with the water and are eventually discharged through the gate-valve, *d′*, by which the height of the water is regulated. The scouring action of the water on the inner surface of A, helps to disintegrate and separate the material. The heavier particles which collect in the upper part of B, are discharged through the opening between A and B, by stopping the feed and reducing the speed.—W. H. C.



Solids from liquids ; Process for obtaining ——. I. S. and O. E. Merrell, Syracuse, N.Y., Assignors to Merrell-Soule Co. U.S. Pat. 1,102,601, July 7, 1914 ; date of appl., Feb. 16, 1912.

The solution is blown, in an atomised condition, into a whirling body of air within a desiccating chamber and at the same time a direct current of air surrounding the spray is blown into the chamber.—W. H. C.

Heating and evaporating liquids ; Method of ——. O. K. Zwingenberger, Perth Amboy, N.J., Assignor to The Roessler and Hasslacher Chemical Co., New York. U.S. Pat. 1,104,285, July 21, 1914 ; date of appl., Nov. 25, 1911.

Hot gas is circulated upwards in a zig-zag path through a system of primary evaporators. The liquid is circulated from the bottom to the top in the evaporators and the hot gas is distributed over a sufficient number thereof to prevent the liquid from reaching the boiling point. From the evaporators the hot gas passes to a series of boilers, the steam generated in which is used for evaporating purposes in any convenient way.—A. S.

Evaporator. L. Hirt. Fr. Pat. 466,496, Dec. 23, 1913 Under Int. Conv., Feb. 21, 1913.

To avoid interruption of the flow of heat by the presenc of bubbles of vapour, or deposited solids, on the heatin surface, the liquid to be evaporated is pumped throug the heating tubes under a pressure, maintained by loade valves, sufficient to prevent boiling ; after passing th valves, it is sprayed into a chamber in which evaporatio takes place.—O. E. M.

Agglomeration of powdered carbon, metals or other material for the preparation of articles used for electrical and othe purposes. Comp. Fr. de Charbons pour l'Electricit Fr. Pat. 466,639, March 8, 1913.

Powdered substances to be agglomerated are mixed wit a small quantity of a binder so that after grinding an mixing, the substance is still in the form of powder. suitable solvent for the binder is then added, and the ma brought to the desired consistence and forced into moul under a pressure of at least 1000 kilos. per sq. cm.—A. T.

Method for carrying out reactions [*by the action of ultr violet rays*]. J. de Kowalski-Wierusz. Fr. Pat. 466,91 Dec. 8, 1913. Under Int. Conv., Dec. 11, 1912.

Substances, especially organic compounds, are expos to the action of ultra-violet rays by passing them vapour, alone or mixed with other vapours, through a hig frequency field, so that they become self-luminous. —O. E. M.

Particles suspended in gases ; Apparatus for the remo of ——. Soc. des Carbures Métalliques. Fr. P 467,267, March 25, 1913.

To remove suspended liquid or solid particles, the ga passed between flat electrodes, consisting of coarse sack attached with graphite and sodium silicate to glass pla and connected to an alternator. The high-tension f thus formed is modified by a glass plate, midway betw and parallel to the electrodes, which collects the suspen particles.—O. E. M.

Cleaning tubular and other vessels [*used for treating p*]. T. Rigby, Dumfries, and N. Testrup, Assignors to W carbonizing, Ltd., London. U.S. Pat. 1,106, Aug. 4, 1914. Date of appl., Dec. 6, 1911.

See Eng. Pat. 9105 of 1911 ; this J., 1912, 677.—T. F. B.

IIa.—FUEL ; GAS ; MINERAL OILS AND WAXES.

Weathering of the Pittsburgh coal bed at the experim mine near Bruceton, Pa. H. C. Porter and A. C. Fiel U.S. Bureau of Mines, Technical Paper 35, pp. 35

The experimental mine comprises an outcrop of the Pittsburgh coal-bed on a hillside. Two nearly horiz galleries were driven about 620 ft. and coals take various distances from the outcrop were compared. Ch in chemical composition have occurred for a distan bout 50 ft. from the outcrop, the amount of cover at is distance being less than 25 ft. The weathered coal ntains less carbon and hydrogen and more oxygen and mbined water in the coal-substance, has a lower calorific lue, absorbs less oxygen from air and liberates less ethane. Boiler tests with clean coal taken at 620 ft., d with "rusty" coal (lumps having yellow coatings of on compounds) taken at 70 ft. from the outcrop, showed differences in evaporative power, furnace efficiency, or rning qualities.—A. T. L.

flammability of gaseous mixtures; The dilution-limits of ——. H. F. Coward and F. Brinsley. Chem. Soc. Trans., 1914, **105**, 1859—1885.

termination of dilution limits.—The results given by evious workers varied over a considerable range, owing different forms of apparatus, and different arrangements r ignition having been used and different standards opted for inflammability. The authors define a gaseous xture as inflammable at a stated temperature and essure if it will propagate flame indefinitely when the burnt portion of the mixture is kept at that temperature d pressure. Combustion in an inflammable mixture is t necessarily complete. In order to conform with this finition, the flame is started near the bottom of a tall ssel which is of sufficient cross-section to minimize the ling influence of the walls, and the bottom of the ssel is sealed in water so that the pressure cannot rise preciably. Upward flame propagation is adopted since very weak mixtures the velocity of propagation may be s than that of the upward convection currents and wnward propagation of the flame may thus be prevented. e largest vessel employed was 1·8 meters high and sq. cm. in section, two sides being made of wood and e of glass. Electric ignition was usually employed

Lowest limits for hydrogen, methane and carbon monoxide air.—Mixtures at atmospheric pressure, and saturated th water vapour at 17°—18° C., were inflammable if ey contained not less than 4·1% H_2, 5·3% CH_4, or 12·5%).—A. T. L.

tural-gas wells; The Hungarian ——. Chem.-Zeit., 1914, **38**, 469.

e occurrence of natural gas in Hungary has long been own, and for some years the gas has been used for ving gas engines. The distribution of the gas for long tances has now been undertaken. In April, 1909, a gas-ring layer was tapped at a depth of 302 meters (990 ft.); wells yield 1·7 million cub. m. (60 million cb. ft.) of (pure methane) per day. It is intended to supply gas for lighting and for power over a wide district, luding the cities of Klausenburg and Marosvásárhely, h 150,000 inhabitants, and to carry the gas eventually Budapest. It is estimated that natural gas could be l in Budapest for 2·4 heller per cub. m. (6·8d. per 1000 ft.), as compared with 7 heller (19·8d. per 1000 cb. ft.) coal gas. The gas is already being distributed over a tance of 75 km. (46½ miles). The rolling stock of the te railways in the district is lighted with the gas, which tored in 40-litre cylinders at 100 atmospheres, and the is also used in several large chemical works, including Portland cement factory. Natural gas and oil have ently been discovered in the north-west of Hungary, r Pressburg, the first boring yielding 1½ wagon-loads oil per day and about 500 cub. m. (17,650 cb. ft.) gas containing 95% CH_4 per hour.—A. T. L.

nbustion in motors. E. Terres. Chem.-Zeit., 1914, **38**, 417.

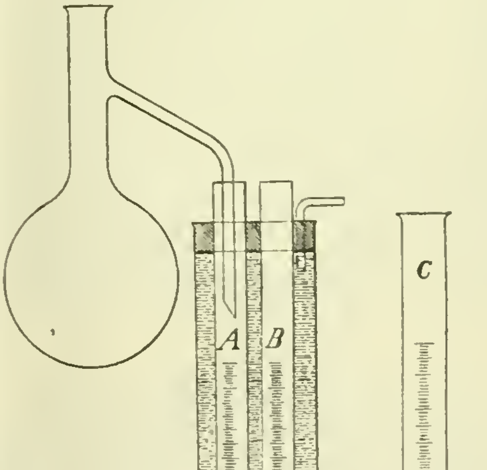
e completeness of the combustion in a four-stroke-le engine working with benzene was found to vary with load, the degree of compression, the timing of the tion, and the quantity of air in the charge. The heat due to incomplete combustion increased from 1·47 to 9% as the load decreased from 3·5 H.P. to no load. —A. T. L.

Petroleums of California; Physical and chemical properties of ——. I. C. Allon, W. A. Jacobs, A. S. Crossfield and R. R. Matthews. Techn. Paper 74, Dept. of Interior, Bureau of Mines, U.S.A. 38 pages.

Tables are given of the results of the fractional distillation of typical oils from different districts. The asphaltic petroleums, after distillation of oils up to 325° C. at 10 to 20 mm. pressure, left a residue of solid elastic asphaltum of technical value. In many cases paraffin wax could be determined by the following method:—The filtered petroleum spirit solution of the sample was treated first with strong and then with fuming sulphuric acid, the petroleum spirit distilled, and the residue dissolved in ethyl acetate. The solution was mixed with 95% alcohol, cooled to 0° C., and the precipitated paraffin wax washed with 75% alcohol, dried and weighed. Under these conditions 2·5 mgrms. of paraffin wax of m. pt. 56° to 58° C. dissolved in 100 c.c. of the solvent. Applying this correction to test mixtures of Trinidad asphaltum and paraffin wax, results were obtained within 0·1% of theory. Refinement of the oils by agitation four times with sulphuric acid, once with sodium carbonate solution, and three or four times with water, and redistillation, showed a total loss of 11% of the oil. In the case of heavier fractions dilution with 1% of pure benzene before the acid treatment obviated difficulties caused by the high viscosity.—C. A. M.

Petroleum; Fractional distillation of ——. J. M. Sanders. Chem. Soc. Trans., 1914, **105**, 1697—1703.

To enable rapid determinations to be made of the specific gravity of successive fractions, a graduated vertical condenser, A, is used, which can be connected by a three-way cock, D, with a discharge tube, E, or with the graduated tube B, and levelling tube, C. The tube, C, is adjusted at the start and at the end of each stage of the fractionation so that water stands at the zero mark on tube, A, and readings are taken of the height of the oil and water levels in A and B respectively. The successive



distillates are run off at E. The levelling tube, C, is graduated so that the quantity of water in the sample of oil can be ascertained from the increase in the amount of water in the tubes A, B, C. For distilling heavy crude oils, containing water which causes frothing, and asphaltic matter which requires heating to the coking stage to ensure complete distillation, a copper-coated distillation flask having two branch tubes at the same level in its neck is used. The flask can be heated very strongly without danger, the expansion of the copper coating separating it from the glass so that a thin film of air is left between them, and the flask is very uniformly heated. Frothing is reduced by passing a current of carbon dioxide into the flask and through the oil by means of one of the branch tubes, and an electrically heated test-tube is inserted in the still-head to prevent condensation.—A. T. L.

Petroleum distillates; Fluorescence of ——. B. T. Brooks and R. F. Bacon. J. Ind. Eng. Chem., 1914, **6**, 623—625.

Evidence is adduced showing that the fluorescence of petroleum oils is not due to resinous or asphaltic constituents in colloidal solution, or to carbon, sulphur, or other substances in colloidal suspension. The fluorescent constituents are only slightly absorbed by fullers' earth and the character of the fluorescence is affected by the addition of various common solvents in the same way as in the case of the fluorescent diamino-derivatives of terephthalic acid methyl ester (Kauffmann, Annalen, 1912, **393**, 1). The fluorescent substance was isolated in a crude state from the acid sludge tar obtained in refining petroleum with sulphuric acid, by washing with water, nearly neutralising the dilute acid solution with lime, filtering, evaporating nearly to dryness, and extracting the residue with alcohol. It probably contains one or more compounds of the benzene series resembling chrysene, fluorene, or pyrene, and is formed to a considerable extent during the distillation of the crude oil, for products obtained by distilling under diminished pressure are much less fluorescent than those distilled at atmospheric pressure. The fluorescence is destroyed by halogenation, hydrogenation, and partly or completely by oxidation. The action of nitro-compounds in neutralising the fluorescence is physical in character, for if an oil "debloomed" in this way be refined with sulphuric acid, a fluorescent product is obtained. A light-coloured oil having only a slight bluish fluorescence, similar to sun-bleached oil can be obtained by shaking lubricating oil with nitrous acid for 3 mins., washing with water, and filtering through fullers' earth, or by treating the chilled oil (not above 10° C.) with oxides of nitrogen and washing with dilute alkali.
—A. S.

Patents.

Fuel; Use of chlorophyll extracts as ——. E. Bouchaud-Praceiq. Fr. Pat. 466,985, March 19, 1913.

The chlorophyll extract may be obtained by means of alcohol or ether, alone or mixed with carbon bisulphide or tetrachloride, or other organic solvents, the plant residue forming a colourless material which can be used for the manufacture of cellulose for paper-making, etc., or as a cattle-food. The residue from evaporating the chlorophyll extract is distilled, alone or with steam, yielding a light fuel oil, suitable for use in internal combustion engines, ammonia which is recovered, and a mineral residue containing phosphates which is useful as a manure.
—A. T. L.

Coal briquettes; Manufacture of ——. Pure Coal Briquettes, Ltd. Fr. Pat. 467,688, Jan. 24, 1914.

Waste coal is ground wet, and the pulp containing 45 to 60 parts of water to 100 parts of coal, is partially dried and solidified by submitting it to a pressure of 500—800 kilos. per sq. cm. between two pistons in a mould having its sides formed by vertical bars which are practically in contact at the inner surface and are tapered towards the outer surface so as to leave spaces for the escape of the water. The briquettes are passed through a tube in which the temperature rises from 80° C. at the inlet end to 250°—500° C. at the discharge end, so that the coal is dried and begins to soften, and the briquettes are compressed while hot at a pressure of 800 to 2500 kilos. per sq. cm.—A. T. L.

Fuel; Briquetted ——. Soc. Internationale des Combustibles Artificiels. Fr. Pat. 467,757, April 4, 1913.

Powdered carbon (*e.g.* wood charcoal), 100 parts, is mixed with sodium silicate, 15—20, and calcium carbonate, 2—3 parts, and briquetted.—A. T. L.

Separating the solid residues of combustion, especially those derived from furnaces; Apparatus for ——. A. F. Müller, Berlin. Eng. Pat. 14,928, June 28, 1913.

The furnace residues are first passed over a reciprocating sieve to remove the fine ashes and then treated with a liquid having a higher specific gravity than the utilisable fuel but lower than the non-combustible residue. The liquid which may be waste dilute molasses from sugar factories or waste from cellulose factories, etc., is contained in a horizontal cylindrical vessel which is half filled. The residues are delivered on to the surface of a rotary sieve and enter the liquid with the latter, as it turns into a horizontal position. The lighter fuel floats off as the sieve sinks, the incombustible residue follows the sieve until the latter is nearly or quite vertical when it falls into the bottom of the cylinder and is removed by a scraper.
—W. H. C.

Vertical retorts for the distillation of coal; Continuous ——. Comp. Générale de Construction de Fours. Fr. Pat. 467,445, Jan. 17, 1914.

The primary and/or secondary air and/or the gases from the generators are preheated by being passed through flues adjacent to the lower part of the retorts, and the waste gases from the combustion chamber are caused to pass through flues adjacent to the preheating flues tc assist in the heating.—W. H. C.

Gas producers; Working of by-product recovery —— T. Rigby and G. W. Andrew, Dumfries, and Wet carbonizing Ltd., London. Eng. Pat. 10,981, May 9 1913.

Peat is gasified in the presence of an excess of steam as in the Mond ammonia-recovery process, and the gase are cooled in two stages so as to separate the more volatil by-products such as methyl alcohol, from the wate and tar. The cooling may be effected in surface con densers, or the gas may first be brought into direct contac with the cooling water under conditions which ensu a final temperature high enough to prevent condensatio of methyl alcohol, and afterwards cooled in a surfac condenser. The gases cooled to atmospheric temperatu may be scrubbed with water or other solvents to recov uncondensed volatile by-products.—A. T. L.

Gas producers and method af working same. J. Stewa Glasgow. Eng. Pat. 21,697, Sept. 26, 1913.

Relates to improvements in producers of the ty described in Eng. Pat. 26,858 of 1909 (this J., 1910, 119 for generating tar-free gas continuously from bitumino coal. The producer comprises a lower, an intermedia and two upper chambers. The lower chamber is provid with a grate and air inlet and is of suitable dimensio for continuous production of gas. The upper chambers a separated from one another by a hollow vertical metal w extending downwards to the top of the intermedia chamber, and serving as an air heater or as a stea generator. Each upper chamber is provided with a fe hopper, air inlet and gas outlet, and with controlli valves. The upper chambers are charged with fresh f alternately, and the newly charged chamber is work with a down-draught of air or air and steam and t other chamber with an up-draught until it needs chargi when the currents are reversed, the lower and int mediate chambers being worked continuously with up-draught. If desired, one of the upper chambers u be fed with anthracite or coke, and the other with bitum ous coal, and the chambers may then be worked c tinuously with up-draught and down-draught respective.

The grate is pivoted and is rocked to agitate the fuel or turned further about a horizontal axis to leave a space for the discharge of ashes into the ash-pit. The upper part of the producer is closed by a hollow casing serving as an air heater or as an evaporator.—A. T. L.

Producer-gas; Process for the production of —— in rotary generators. Alpine, Maschinenfabrikges. m. b. H. vorm. Holz-Häner'sche Maschinenfab. G. m. b. H. and F. Meyer. Fr. Pat. 466,860, Dec. 27, 1913. Under Int. Conv., Jan. 10, 1913.

Oxidation (combustion) of the fuel is effected in an auxiliary furnace and the gases are introduced into the rotary furnace where destructive distillation is carried out, under such conditions as to composition and temperature that no fusion of the ash takes place.—W. H. C.

Generation of mixed steam and combustion products under pressure for the purpose of power. J. B. Kinnear, Kinloch, Fife. Eng. Pat. 22,775, Oct. 9, 1913.

Solid, liquid or gaseous fuel is burnt with air under pressure in an hermetically-sealed furnace, connected with a steam-chamber, and water is injected into the hot products of combustion until the temperature of the mixed gases passing to the steam-chamber is reduced to the desired point. (Reference is directed to Eng. Pats. 3556 of 1877, 23,828 of 1893, 573 of 1894, and 4278 of 1902.)—A. T. L.

Gas-purification; Apparatus for ——. C. Heine. Fr. Pat. 466,459, Dec 22, 1913.

The gas passes upwards through a series of flat drums perforated with small holes at the bottom, and large ones, fitted with internal baffle-plates, at the top. The drums are in a gas-tight casing from which they can be removed separately.—O. E. M.

Petrol or like fuel; Method of increasing the efficiency of —— in internal-combustion engines. J. E. Birtill, Manchester. Eng. Pats. 15,524 and 17,539, July 5 and 31, 1913.

The petrol, before entering the carburettor, is mixed with about 0·05 of its quantity of a soluble lubricating oil. —A. T. L.

Fuel suitable for use in internal-combustion engines; Manufacture of ——. P. H. King, London. Eng. Pat. 15,970, July 10, 1913.

A petrol substitute consisting of heavy hydrocarbons, such as a petroleum distillate boiling from 100°—350° C., mixed with a standard saturated solution of acetylene in benzene.—A. T. L.

Light oils; Production of —— from crude, heavy, or lighting oils. J. Moeller and H. C. Woltereck, London. Eng. Pat. 16,611, July 19, 1913.

The vapours of the crude oil are mixed with steam at 700°—800° C. under atmospheric pressure and passed through tubes filled with coke and heated to 600°—700° C. A large yield of light oils free from sulphur is obtained. —A. T. L.

Combustible liquid from heavy hydrocarbons; Process for the manufacture of ——. W. A. Hall. Fr. Pat. 467,381, Jan. 16, 1914. Under Int. Conv., Oct. 28, 1913.

The gases and liquid distillates from "gas oil" distilled under pressure, after separation and purification from tarry substances, are passed together through a retort heated to about 200° C. and at a pressure of about 3½ atmospheres. The gas combines with the oil to form a liquid suitable for internal combustion engines.—W. H. C.

Coke; Process for the production of ——. L. Franck, Luxemburg. U.S. Pat. 1,098,359, May 26, 1914. Date of appl., Jan. 6, 1914.

See Ger. Pat. 274,853 of 1914; this J., 1914, 782.—T. F. B.

Heating gases; Process for obtaining ——. "Athion" Ges.m.b.H., Mannheim-Waldhof, Germany. Eng. Pat. 21,213, Sept. 19, 1913. Under Int. Conv., Sept. 21, 1912.

See Fr. Pat. 462,740 of 1913; this J., 1914, 304.—T. F. B.

Gas-producer. J. A. Weil, Stockton-on-Tees. U.S. Pat. 1,105,474, July 28, 1914. Date of appl., May 16, 1914.

See Eng. Pat. 4452 of 1914; this J., 1914, 636.—T. F. B.

Gases; Treating illuminating and heating —— for purifying them and obtaining useful products therefrom. "Athion" Ges. m. b. H., Mannheim-Waldhof, Germany. Eng. Pat. 17,877, Aug. 5, 1913. Under Int. Conv., Aug. 7, 1912.

See Fr. Pat. 461,107 of 1913; this J., 1914, 244.—T. F. B.

[Mineral] oil; Apparatus for mixing —— with chemicals. O. J. Shiner, Bayonne, N.J. (M. E. Shiner, Administratrix). U.S. Pat. 1,102,696, July 7, 1914. Date of appl., Feb. 2, 1914.

See Eng. Pat. 13,441 of 1913; this J., 1914, 740.—T. F. B.

Treatment of [mineral] oils [for medicinal purposes]. Eng. Pat. 15,551. *See* XX.

Calorimeter for gas and other fuels. Fr. Pat. 467,180. *See* XXIII.

IIb.—DESTRUCTIVE DISTILLATION; HEATING; LIGHTING.

Bunsen flame; Influence of secondary air on the inner cone of the ——. L. Ubbelohde and O. Dommer. J. Gasbeleucht., 1914, **57**, 733—740.

A mixture of gas and air containing less air than is necessary to form an explosive mixture, will burn at the orifice of a tube with a flame having an inner cone. This is due to the fact that combustion effected by secondary air (*i.e.*, air derived from the atmosphere about the flame) extends within the inner cone. Experiments made with a burner 0·7 cm. diam., with mixtures of carbon monoxide and air, showed that the velocity of the gases at the surface of the inner cone, *i.e.*, the velocity of flame propagation in the mixture of gas and air, was increased by the secondary combustion when the mixture contained 60% CO or more, and the temperature of the inner cone was similarly raised when the mixture contained 45% CO or more. By analysing gases withdrawn from various parts of the flame it was found that the inner cone contained products from the secondary combustion when the gas mixture contained 50% CO or more, and with 85% CO the gases in the inner cone contained nearly double the quantities of carbon dioxide and nitrogen that could be formed by the primary combustion alone. The maximum flame temperature of carbon monoxide was obtained with a mixture containing CO 34, air 66%. With large quantities of primary air in the gas mixture, combustion in the inner flame was very incomplete. —A. T. L.

Wood; Steaming of ——. Heuser. *See* V.

Patents.

Decolorising-carbon; Regenerating ——. A. Wijnberg, Amsterdam. Eng. Pat. 17,432, July 29, 1913. Addition to Eng. Pat. 19,357, Aug. 23, 1912 (this J., 1913, 85).

Carbon revivified as described in the principal patent loses its efficiency after about 15 to 20 repetitions of the process. It can then be regenerated by treating with a solution (1% to 25%) of alkalis, alkaline compounds, or alkaline-earths, with or without an oxidising agent, and heating to red heat or incandescence. The regenerated carbon may be revivified after use as described previously (*loc. cit.*).—A. T. L.

Filaments for incandescent electric lamps ; Manufacture of metallic ——. J. A. Scoular and Dick, Kerr and Co., Ltd., London. Eng. Pat. 14,807, June 26, 1913. Addition to Eng. Pat. 11,455, May 14, 1912 (this J., 1913, 527).

Tungsten powder is mixed with a small proportion of sodium silicate and squirted into filaments, which are straightened, dried in hot air and heated to bright redness in an atmosphere of hydrogen. They are then treated with a solution of hydrofluoric acid, washed, dried, and heated to a sintering temperature.—W. H. C.

Electric incandescent lamps ; Manufacture of ——. F. Simpson, Liverpool. Eng. Pats. 15,297, July 2, 1913, and 2612, Jan. 31, 1914.

Tungsten filaments or bars are manufactured in bulk from a paste made of tungsten or its oxygen compounds and an organic binding material. The filaments are squirted, and dried in air at 150°—200° C. Batches of 500 or more of the dry filaments are hung over T-shaped tungsten supports, and carried by power-driven mechanism into a tubular resistance furnace which is kept at about 900° C. and through which a current of dry hydrogen, free from nitrogen and oxygen, is passed. The filaments are heated in the furnace for about 30 mins. to carbonize the binder and reduce the tungsten to metal. They are then heated to 240° C. in an oven to which air has access, so as to produce more oxide than is sufficient for the decarbonisation of the filaments, this being effected by heating for ½ to 20 mins. at 1800° C. in an atmosphere of hydrogen in a furnace consisting of a resistance tube of pure iridium. Alternatively the re-oxidised filaments may be heated *in vacuo* for 6—8 mins. at 800°—950° C., so as to remove carbon, and are sintered by heating for 2—5 mins. to 1800° C. in hydrogen. (See also Eng. Pats. 11,409, 13,596, and 21,509, of 1906, 8947 of 1907, 12,720 of 1908 and 15,192 of 1909; this J., 1907, 462, 1131 ; 1908, 798 ; 1909, 788).—A. T. L.

Electrodes suitable for electric arc lamps. The British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, N.Y., U.S.A. Eng. Pat. 18,355, Aug. 12, 1913.

The electrodes are composed of magnetite 70, rutile 30, and lithium fluoride or other lithium compound, 1 part. —W. H. C.

Arc light carbons. H. Ayrton, London. Eng. Pat. 6104, March 10, 1914. Addition to Eng. Pat. 1775, Jan. 22, 1913 (this J., 1914, 346).

The carbon is similar to that described in the principal patent but has an additional thin layer of copper or other metal between the hard core and the soft outer shell. —A. T. L.

Metallic filaments for electric incandescent lamps ; Manufacture of ——. J. A. Scoular, Hammersmith, Assignor to Dick, Kerr and Co., Ltd., London. U.S. Pat. 1,104,557, July 21, 1914. Date of appl., March 14, 1913.

See Eng. Pat. 11,455 of 1912 ; this J., 1913, 527.—T. F. B.

III.—TAR AND TAR PRODUCTS.

Patents.

Triaminocarbazolemonosulphonic acid ; Process for preparing ——. L. Cassella und Co. Ger. Pat. 275,975, July 1, 1913.

Carbazole is highly sulphonated, preferably until a trisulphonic acid is formed, and the product is treated with powerful nitrating agents. This results in the replacement of sulphonic groups by nitro groups, and also in the introduction of a further nitro group, with the formation of a trinitrocarbazolemonosulphonic acid, convertible by reduction into triaminocarbazolemonosulphonic acid. —T. F. B.

Pitch, resin, and the like ; Granulation of ——. C. N. Stevens, Chicago, U.S.A. Eng. Pat. 25,567, Nov. 8, 1913. Under Int. Conv., April 10, 1913.

See U.S. Pat. 1,088,635 of 1914 ; this J., 1914, 413.—T.F.B.

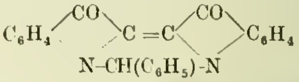
Dinitro-diaminobenzophenone. L. Blangey, Mannheim, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 1,104,611, July 21, 1914. Date of appl., Feb. 26, 1914.

See Eng. Pat. 8690 of 1914 ; this J., 1914, 743.—T. F. B.

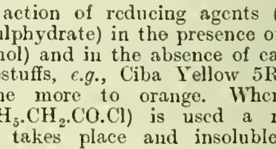
IV.—COLOURING MATTERS AND DYES.

Indigo ; Some new derivatives of —— *and other indigoid dyestuffs.* G. Engi. Chem.-Zeit., 1914, **38**, 199.

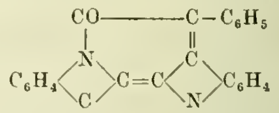
A description of the dyestuffs of the Indigo Yellow series discovered by the author and I. Fröhlich (Eng. Pats. 29,368 of 1910 ; 8900 of 1911 ; 8421 and 9940 of 1912 ; and Ger. Pat. 263,470 ; this J., 1911, 1247 ; 1912, 22,635, 766 ; 1913, 1005). Indigo Yellow 3G, made by condensing indigo with benzoyl chloride in a neutral solvent in the presence of copper powder, is regarded as having the constitution



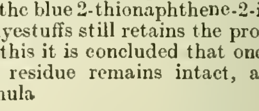
Its bromo-derivative is known as Ciba Yellow G and from this by the action of reducing agents (sodium hydrosulphite or sulphydrate) in the presence of an indifferent solvent (alcohol) and in the absence of caustic alkali are obtained dyestuffs, *e.g.*, Ciba Yellow 5R of which the shades incline more to orange. When phenylacetyl chloride ($C_6H_5.CH_2.CO.Cl$) is used a more extensive condensation takes place and insoluble products are obtained incapable of giving vats but valuable as pigments on account of their fastness to light, *e.g.*, Lake Red Ciba B. The product obtained by condensing indigo with phenylacetyl chloride probably has the constitution



The green β-naphthylindigo gives a red pigment dyestuff. The sulphonic acids of these products are wool dyestuffs. In the case of the blue 2-thionaphthene-2-indole-indigo the resulting red dyestuffs still retains the property of forming a vat. From this it is concluded that one carbonyl group of the indigo residue remains intact, as shown in the suggested formula



2-Naphthalene-2-indole-indigo condensed with phenylacetyl chloride gives a vat dyestuff dyeing bright but fugitive carmine-red shades. It probably has the constitution



—J. B.

Indigo ; Halogenated —— *and derivatives.* E. Grandmougin and P. Seyder. Ber., 1914, **47**, 2365—2373. (See also this J., 1910, 553.)

5.7.5.′7′-Tetrachloroindigo (Brilliant Indigo B ; Fr. Pa 315,180 ; this J., 1902, 401) is redder than the tetrabrom indigo (Ciba Blue 2B, Brilliant Indigo 4B; Ber., 1909, 42, 4408; this J., 1910, 14). It gives on oxidation 5.7-dichloroisatin. 4.4′-Dichloro-5.5′-dibromoindigo (Brilliant Indigo 4G; Ger. Pat. 234,961) oxidises to 4-chloro-5-bromoisatin. 4.7.4′.7′-Tetrachloroindigo (Ber., 1884, 17, 752; this J., 1884, 411) gives similarly 4.7-dichloroisatin. Octochloroindigo (Annalen, 1912, 48, 473) dyes in blue violet tones and gives on oxidation 4.5.6.7-tetrachloro-satin. 6.6′-Di-iodoindigo is obtained from 6.6′-diamino-ndigo (Monatsh. Chem., 26, 1253) by diazotising in ulphuric acid solution and decomposing with potassium odide. It dissolves in hot nitrobenzene or methyl enzoate with a violet colour, turning pure blue on cooling. 6.6′-Dibromoindigo (Ger. Pat. 195,291) has also been prepared by the Sandmeyer reaction. 6.6′-Diamino-5.7.5′.7′-tetrabromoindigo is a brown dyestuff (Ciba Brown R), although the unbrominated diaminoindigo is worthless. The absorption spectra of the different ndigo derivatives have been determined.—J. B.

m-Aminophenol and m-anisidine; Nitro-derivatives of the acidyl-derivatives of ——. F. Reverdin and K. Widmer. Chem.-Zeit., 1914, **38**, 276.

By nitrating the diacetyl-, dibenzoyl- and ditoluene-ulphonyl compounds of *m*-aminophenol, the 4- and 6-mononitro derivatives have been obtained. The four ossible mononitro-*m*-anisidines have also been obtained y nitrating and saponifying acetyl-*m*-anisidine. The -mononitro-compound melts at 169° C., the 2-mononitro-ompound at 143° C. The other two are known. Further itration yielded 4.6-, 2.4- and 2.6-dinitro-*m*-anisidine, he latter compound melting at 146° C. Trinitro-erivatives were not obtained.—J. B.

itro-m-anisidines; Comparison of the azo dyestuffs from —— with those from the corresponding nitranilines. F. Reverdin and K. Widmer. Chem.-Zeit., 1914, **38**, 276.

s the orange and red dyestuffs the introduction of the ethoxy-group caused the shade to incline towards red r violet. 4-Nitro-*m*-anisidine gave dyes of brighter shades an the 5-isomeride. The dyestuffs from the 5-isomeride nd naphthionic acid, 1.4-naphtholsulphonic acid and 3.6-naphtholdisulphonic acid are distinguished for stness to light.—J. B.

urpurogallin; The yield of —— by oxidation of pyrogallol with peroxydase and hydrogen peroxide. A. Bach. Ber., 1914, **47**, 2125—2126.

HE highest yields previously obtained by Bach and hodat (this J., 1904, 505) were 16·2 and 16·8%. öcklin's yield of 50% (Dissertation, Geneva, 1907) used the author to re-investigate the matter, using a ry active peroxydase obtained by the ultrafiltration ethod (see preceding abstract) and with various pro-rtions and concentrations of hydrogen peroxide. Never ore than half Stöcklin's yield was obtained, however, d the possibility of error due to retention of water by e voluminous purpurogallin precipitate is suggested. very sensitive test for purpurogallin is to dissolve the tter in alcohol or acetone, dilute with 3 vols. of water d add peroxydase and hydrogen peroxide. A violet loration results, gradually becoming brown. One part purpurogallin in 500,000 can be detected. Phenolase ves the same reaction. The yield of purpurogallin from rogallol is evidently dependent on the avoidance this reaction by separation of the purpurogallin from e solution as quickly as possible.—J. B.

PATENTS.

louring matters of the anthracene series; Manufacture of ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. Eng. Pat. 21,133, Sept. 18, 1913.

dyestuffs which produce violet shades on vegetable res are obtained by condensing halogenated fluorenene-boxylic acids with 1-aminoanthraquinone. During the ocess the carboxyl group is split off, giving products identical with those obtained by condensing halogenated fluorenones with 1-aminoanthraquinone (see Addition to Fr. Pat. 365,920; this J., 1910, 1197).—T. F. B.

Azo-dyestuffs; Production of ——. Chem. Fabr. Griesheim Elektron, Frankfurt a/M., Germany. Eng. Pat. 3313, Feb. 7, 1914. Under Int. Conv., April 19, 1913.

ARYLIDES of 2.3-hydroxynaphthoic acid are condensed with formaldehyde in alkaline solution (Eng. Pat. 3312 of 1914; this J., 1914, 742). The new products may be combined with diazo compounds just as in the case of the parent materials (see also Eng. Pats. 6379 of 1912 and 17,279 of 1913; this J., 1912, 635 and 1914, 73).—J. B.

Azo dyestuffs; Production of new ——. Chem. Fabr. Griesheim Elektron. Fr. Pat. 466,922, Dec. 26, 1913.

THE diazo-compound of an aminoarylamide of an *o*-hydroxycarboxylic acid of the benzene series is combined with a suitable end component. For example 1.4-naphtholsulphonic acid with the *p*-aminoanilide of salicylic acid gives a red which dyes wool fast to washing and milling.—J. B.

Nitrosulphochlorides of ortho-oxycarboxylic acids or of their derivatives; Manufacture of ——. Farbenfabr. vorm. F. Bayer und Co., Leverkusen, Germany. Eng. Pat. 12,061, May 15, 1914. Under Int. Conv., May 29, 1913.

THE sulphochlorides of phenol-*o*-carboxylic acids or their derivatives can be converted into nitro compounds by nitration in the usual manner. The *p*-sulphochloride of salicylic acid is converted into a nitro derivative ($OH : COOH \cdot SO_2Cl : NO_2 = 1 : 2 : 4 : 6$). The products may be used as intermediate compounds in the manufacture of azo dyestuffs.—T. F. B.

Polyazo dyestuffs; Preparation of green substantive ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pats. 276,140, May 3, 1913, and 276,141 and 276,142, Aug. 5, 1913.

(1.) AN aromatic acidyldiamine or nitroamine, or a derivative or sulphonic acid thereof, is diazotised and combined with a diazotisable amino compound; the product is diazotised and combined with a *m*-aminobenzo derivative of 2.5-aminonaphthol-7-sulphonic acid, and the disazo dyestuff thus produced is diazotised and combined with resorcinol or *m*-aminophenol, the product being finally saponified or reduced. When dyeings with such compounds are treated with formaldehyde, fast green shades are produced. The *m*-aminobenzo derivatives, mentioned above, may be the *m*-aminobenzoyl derivative, or *m*-aminobenzenyl-1.2-naphthylenediamine-7-sulphonic acid, or the benzonaphthothiazole, etc. (2.) The dyestuffs obtained according to the preceding patent are diazotised and combined with resorcinol or *m*-aminophenol, or a diazotised acidyldiamine or nitroamine is combined with an amino compound, the product is diazotised and combined with a *m*-aminobenzo derivative as above, the disazo dyestuff is saponified or reduced, and the product is tetrazotised and combined with two mols. of resorcinol or *m*-aminophenol, or with one mol. of each. (3.) The acidyldiamine or nitroamine in Ger. Pat. 276,140 is replaced by α- or β-naphthylamine or their sulphonic acids.—T. F. B.

Amino-anthraquinones; Process of producing ——. R. Uhlenhuth, Assignor to Farbwerke vorm. Meister, Lucius, und Brüning, Höchst on Maine, Germany. U.S. Pat. 1,104,943, July 28, 1914. Date of appl., June 2, 1913.

ANTHRAQUINONESULPHONIC acids are converted into the corresponding aminoanthraquinones by heating them with aqueous ammonia in such a manner that the sulphurous acid produced is converted into a practically insoluble metallic salt; for example, the reaction may be carried out in presence of barium chloride or other soluble barium salt.—T. F. B.

Dyestuffs ; Preparation of brown, chrome —— for wool. Fab. Prod. Chim. ci-dev. Sandoz. Fr. Pat. 467,114, Jan. 8, 1914. Under Int. Conv., Nov. 23, 1913.

Resorcinol is combined on the one hand with a diazobenzene sulphonic acid or the diazo-compound of a monoazo dyestuff made by combining Clève's acid with a diazobenzenesulphonic acid or an o-diazophenol, and on the other with an o-diazophenol or the diazo-compound of a monoazo dyestuff made by combining Clève's acid with an o-diazophenol. The new dyestuffs dye wool directly in brown shades sufficiently fast to milling and potting for ordinary purposes, becoming still faster on after-chroming. (Compare Ger. Pat. 251,844 ; this J., 1912, 1117.)—J. B.

[Azo] colouring matters capable of being further developed ; Manufacture of ——. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 20,714, Sept. 13, 1913.

See Ger. Pat. 273,934 of 1913 ; this J., 1914, 783.—T. F. B.

Dyes for dyeing furs, hairs, and the like. A. Erlenbach and K. Marx, Dessau, Assignors to Act.-Ges. f. Anilinfabr., Berlin. U.S. Pat. 1,105,501, July 28, 1914. Date of appl., Nov. 6, 1912.

See Addition of May 7, 1912, to Fr. Pat. 413,877 of 1910 ; this J., 1912, 1121.—T. F. B.

Sulphurised dyes and process of making same. H. Heimann, Dessau, Assignor to Act.-Ges. f. Anilinfabr., Berlin. U.S. Pat. 1,105,515, July 28, 1914. Date of appl., Oct. 16, 1912.

See Fr. Pat. 436,373 of 1911 ; this J., 1912, 426.—T. F. B.

Mordant dyestuffs ; Green —— and process of making. E. Bodmer, Assignor to Dye-Works, formerly L. Durand, Huguenin und Co., Basle, Switzerland. U.S. Pat. 1,106,185, Aug. 4, 1914. Date of appl., July 3, 1913.

See Fr. Pat. 459,681 of 1913 ; this J., 1913, 1101.—T. F. B.

V.—FIBRES ; TEXTILES ; CELLULOSE ; PAPER.

Wool ; The presence of an amino-group in ——. K. Gebhard. Färber-Zeit., 1914, **25**, 279—283. (See this J., 1914, 251 and 640.)

Kann's conclusion that wool contains no amino-group is disputed. Wool treated with formaldehyde under the conditions described by Kann still retains its power of reacting with nitrous acid to form a true diazo-compound. This is explained by the author's theory that wool contains two substances, an amino-acid and a colloidal substance loosely attached to the amino-groups of the acid. Kann probably effected the splitting off and coagulation of this colloid, leaving free the amino-acid with an active amino-group.—J. B.

Cellulose for making cellulose solutions ; Preparation and requirements of ——. C. Piest. Papierfab., 1914, **12**, 860—865.

For guncotton the material most largely employed is a mixture of spinning waste and American "linter-waste." The threads are first torn up and the lint passed through a cleaning machine to remove all mechanical impurities. Oil, natural wax, proteins, etc. are then removed by digesting with about 1% caustic soda solution under 3 atmos. pressure. The material must be tightly packed in the boilers and good circulation ensured ; high purity of the soda and the exclusion of air during boiling and washing are advantageous. Bleaching must be very carefully controlled to preserve the chemical integrity of the cellulose ; a little acetic acid may be added. The "copper value" (Schwalbe's test) must not exceed 1·0 ; fat and waxy matters, extracted by absolute alcohol, 0·5% ; wood-gum, 2%. Tissue paper, from sulphite wood pulp, may also be used for nitrating but is dearer than cotton-waste and yields an inferior product. For celluloid, great mechanical purity is required to avoid specks in the product ; a low "copper value," not above 1·0 is specified. For collodion cotton, long fine fibres and freedom from metallic impurities are required. For nitro-artificial silk, resin and oil are most objectionable impurities ; as highly concentrated solutions of low viscosity are employed, the degree of bleaching, as indicated by the "copper value," may be higher. Wood celluloses give a softer but weaker silk ; they should be purified by boiling under pressure with dilute sodium carbonate solution with the addition of a little caustic soda or sodium sulphide. For leather-substitutes the requirements are the same as for celluloid, but a higher degree of bleaching may be permitted. For cellulose acetate, freedom from knots is an additional requirement. For cuprammonium silk also, the cotton must be free from knots and the "copper value" must not exceed 1·0. According to one process, the cotton is bleached, then mercerised, washed, centrifuged and dissolved without drying. For viscose, only wood cellulose is employed, generally purified by steeping in 2% hydrofluoric acid and then boiling out with 1% caustic soda ; the "copper value" should not exceed 4·0.—J. F. B.

Celluloid chemistry ; Problems of ——, *and the necessity of colloid-chemical views in this industry.* H. Schwarz. Kolloidchem. Beihefte, 1914, **6**, 90—126.

Celluloid may be regarded as a solid colloidal solution of nitrocellulose and camphor and the process of manufacture consists of two stages : the conversion of a mixture of nitrocellulose and camphor into a celluloid-gel by means of alcohol, and the conversion of the gel into celluloid by hot rolling and drying, whereby the alcohol is removed ; the stability of the system is increased in both stages of the process. Two factors of great importance in regard to the suitability of nitrocellulose for celluloid manufacture are the magnitude of the latent acidity (*i.e.*, acidity developed when nitrated paper which has been washed until neutral is subsequently subjected to certain treatments such as beating, washing with hot water, etc.) and the ease with which such latent acidity becomes manifest. Celluloid also shows the phenomenon of latent acidity an part of this latent acidity may become manifest in th operation of hot pressing. The nature and causes of number of defects of celluloid are discussed and also th so-called "antazide" treatment. In the case of a colloida system such as celluloid, an antazide will be more effectiv the larger the size of its particles and the more colloida its character : in agreement with this, solids are found t be more effective than liquids and the substituted urea superior to urea itself. The efficacy of an antazide in creases, within limits, with the quantity used, but it i possible that certain colouring matters may interfere wit the action, since it is known, for example, that the additio of some Erythrosine solution prevents the precipitation silver bromide from its solution by sodium sulphate. solid antazides those which also act as colouring matte (zinc white, zinc carbonate, white lead, etc.) are mo largely employed. All pigments and mineral colou must be regarded as antazides and it is irrational attempt to increase the stability of celluloid coloured wi a pigment by addition of a special antazide. Opaque coloured celluloid is more stable than the transpare material, and treatment with special antazides, apa from the colouring matters and gelatinising agents used the ordinary course of manufacture, should never resorted to except after taking all precautions to ensu that the nitrocellulose used is of good quality a stability.—A. S.

Wood ; The steaming of ——. Heuser. Chem.-Ze 1914, **38**, 126—127.

The by-products formed in the steaming of wood brown mechanical pulp at 4 atmos. pressure for 8 ho were examined at intervals. They included organic aci sugars, resin, mineral salts, incrusting matters, tanni furfural. It may be assumed that the resins, tanni incrusting matters and salts are extracted from the w without chemical change. The acetic and formic ac are produced by the decomposition of the lignone ;

sugar and furfural are formed from the carbohydrates. The "browning" may be regarded as a first step towards carbonisation. The formation of organic acids reached a maximum after 4—6 hours' steaming. The analytical separation of acetic and formic acids was complicated by the presence of sugar; they were separated from this by distillation *in vacuo* and then determined by Lieben's method (this J., 1894, 288). The yield calculated from 100 kilos. of wood was 213 grms. of acetic acid and 32 grms. of formic acid. These numbers would vary according to the species of wood; pine wood yielded more formic acid. The sugar was estimated as dextrose; the maximum production from spruce wood was found after steaming for 2—5 hours, from pine wood after steaming for 4—6 hours. The total quantity from pine wood was greater than from spruce; the highest value found was 0·52% of the solid wood. The maximum amount of resin was separated in the early stages of the process but was too small for profitable recovery. The furfural appears to be formed either by the direct action of the steam and inorganic salts or else by the action of the steam and organic acids, the latter playing the part of hydrochloric acid. Müller stated that if the wood be immersed for a short time in caustic soda before steaming, the consumption of power in the grinding process is reduced by 25%; by blowing in the alkali with the steam the economy of power has been increased to 45%.—J. F. B.

Paper pulp; Suitability of long-leaf pine for ——. H. E. Surface and R. E. Cooper. U.S. Dept. Agric., Bull. No. 72, May 29, 1914, 1—26.

Digestions were made with Southern long-leaf pine material, logs and edgings, in a stationary vertical boiler of 62 galls. capacity. The high density of the wood, 3550 lb. oven-dry weight per solid cord of 100 cb. ft. green volume, is favourable from the point of view of yield. Mild conditions of digestion by the sulphate process gave high yields (61%) of fibre, somewhat harsh in character but suitable for papers of kraft type of moderate strength. The best results were obtained with a lye containing 15 lb. NaOH and 7·5 Na_2S per 100 lb. of chips, at the rate of 0·68 gall. per lb. of material; the maximum pressure of 100 lb. per sq. in. was maintained for 3 hours; total time, 3½ hours. Under these conditions the yield was reduced to 48·4—49·1%, but the papers produced from the pulp were as strong and as resistant to wear as the best imported "krafts," and possessed the characteristic "leathery" handle. In the digestions with caustic soda alone, the best results were obtained with a liquor containing 20 lb. NaOH per 100 lb. of wood, at an initial concentration of 79·7 grms. per litre; steam-pressure 110 lb. per sq. in. for 5 hours; total time 6 hours. The yield was 48% of pulp, which gave papers of excellent quality. The sulphate process is superior in all respects to the caustic soda process, particularly as regards time. The presence of inactive salts, such as sodium sulphate and carbonate serves no useful function; there appears to be, for each different combination of digestion conditions, some definite minimum proportion of sodium sulphide to caustic soda necessary to produce the characteristic toughness of kraft pulps, but as the sulphide is increased the odour becomes more pronounced. Plain soda pulps from long-leaf pine tend to be soft and "fluffy" if well boiled, and do not acquire the same degree of "greasiness" in beating as the sulphate pulps; they are generally less resistant to rubbing, even if the tensile strength is good. Soda pulps, if underboiled, will not give even moderately good papers, and the maximum yield at which papers can be made is only about 50%, whereas with the sulphate process, fairly strong papers can be made from underboiled pulps prepared with a yield of 60%.—J. F. B.

Sulphite pulp manufacture; Notes on ——. A. Frohberg. Chem.-Zeit., 1914, **38**, 126.

The idea that the system of digesting with indirect steam is superior to the direct steam system is not correct. When boiling with live steam the circulation is much better and the mixing of the "acid" and raising of the temperature are more rapid. Below 100° C. adsorption phenomena occur, the colloidal wood adsorbing sulphurous acid from the liquor; consequently high concentration and maximum surface development are favourable. The chief objection to the direct steam system is the necessity for blowing over large quantities of liquor owing to the dilution. The liquors thus driven over and regenerated contain organic matters which weaken the efficiency of the "acid" by promoting the decomposition of the sulphurous acid into trithionic acid. It is better to separate the gases from the liquors blown over and utilise them separately. The organic matters in the "acid" may be determined colorimetrically after driving off the sulphurous acid, or oxidising by hydrogen peroxide. Acid produced in the towers at 3—3·2% strength can be enriched up to 4·5% by a systematic regeneration process. Blowing over also causes loss of heat; the necessity for blowing over increasea with steam of low heat-capacity; the use of superheated steam up to 220° C. affords a considerable economy in this direction. Good distribution of superheated steam is essential; a maximum digestion temperature of 145° C. does not injure the quality of the cellulose. When pneumatic stamping machines are used to increase the quantity of the charge, the strength of the "acid" should be increased. Dry wood shows a higher adsorption capacity than fresh; artificial drying by waste heat or hot air is very advantageous. In producing sulphurous acid, rich and cool gases are desirable. The formation of sulphur trioxide is at a maximum at 400°—500° C.; at 900°—1000° C. the sulphur trioxide is decomposed again into sulphur dioxide and oxygen. The furnace therefore must be worked as hot as possible in order to obtain gases rich in sulphur dioxide; the gases must be immediately cooled by direct spraying with water to reduce the temperature to 90°—100° C., the formation of sulphur trioxide being thus reduced to a minimum.
—J. F. B.

Coniferous woods; The resin of —— and its removal from sulphite-cellulose. C. G. Schwalbe. Chem.-Zeit., 1914, **38**, 926.

The "resin spots" of paper are caused by a mixture of resin and fat. The resin itself is hard, but the mixture is plastic, hence the fat content is the real cause of the markings. The fat consists mainly of the glyceride of oleic acid and some linolic acid. For the removal of this impurity from sulphite-cellulose an emulsifying agent is suggested. Alkalis in the proportion of 1% NaOH or Na_2CO_3 on the weight of the material remove 70—80% of the resin and fat, but affect the cellulose. Borax or "tetrapol" soap remove 50—70%. Emulsifying agents capable of acting in acid solution would be especially valuable. Twitchell's reagent (this J., 1900, 254), for example, removed 50%.—J. B.

Fibres; Observations on bleaching soda and sulphite [wood-pulp] ——. E. Sutermeister. Papierfab., 1914, **12**, 898—900.

Investigations were made with poplar soda pulp requiring 11·5% of bleaching powder, easy bleaching sulphite requiring 5% and medium sulphite requiring 13% to produce a standard colour at 40° C., when acting for 11—13 hours. Bleaching at 68° C. instead of 40° C. gave a poorer colour than the standard. Bleaching with very much larger proportions of bleach liquor gave in all cases a higher colour than the standard, but increments of bleach did not always produce proportional increments of colour. Of the two sulphite pulps the easy bleaching sample responded more readily to an excess of bleach than the poorer grade while the soda pulp showed less improvement still. In bleaching with potassium permanganate, 1 part produced the same effect as 1·85 parts of bleaching powder. In this case the use of an excessive proportion produced a maximum effect upon the soda pulp and had least effect on the higher grade sulphite. The results obtained by bringing the pulp to the standard colour by bleach liquor and producing the higher whites by permanganate showed little advantage in cost over permanganate alone. In producing high whites with excess of hypochlorite the loss in weight increased as the action was intensified but was less with the permanganate bleach than with the hypochlorite bleach. The destructive effect of high bleaching on the fibre was studied (*a*) by the "copper value," (*b*) by the loss on boiling with 0·25% caustic soda; the two methods gave parallel results. Mechanical tests of papers prepared from the pulps showed that moderate bleaching tended to increase rather than decrease the strength as compared with the same pulps in the unbleached condition.—J. F. B.

Loading materials [*for paper*]; *The behaviour of* —— *to dyestuffs.* P. v. Ehrenthal. Chem.-Zeit., 1914, 38, 87.

The adsorption of various types of dyestuff used in paper making by the various filling materials—talc, china clay, asbestine and *blanc fixe*—was investigated with a view to devising a method of rapidly estimating the value of a given loading material. Irregularities in the adsorption curves show that the method must be used with discretion.—J. B.

Paper; Removal of ink from printed ——. H. Wangner. Chem. Zeit., 1914, 38, 927—928.

In removing the carbon of printers' ink from waste papers it is necessary first to decompose the linseed oil medium by the action of alkali and then to pulp the paper without direct pressure, in order to avoid fixing the particles of carbon on the fibres. In the author's process, the yellowing of the mechanical wood fibre by the action of the alkali is prevented by the use of a special bleaching-soda, which contains about 3% Na_2O_2. The paper is fed dry into one end of a perforated steeping drum revolving slowly in a trough containing a 1% solution of this alkali, heated to a temperature depending on the class of paper under treatment, 30°—40° C. for news paper. The interior of the drum is provided with helical passages and a special scoop removes a given quantity of the steeped material from the delivery end at each revolution. This material falls into a helical compressor which squeezes out the excess of lye to be pumped back to the steeping trough and delivers the paper as a cake to the pulping machine. The latter is arranged vertically and contains a rotating bell provided with blunt teeth. The material travels down between the bell and the outer mantle and then rises up inside the bell till it reaches the top of a stationary central cylinder. By that time it is completely pulped by the action of the teeth, and it is washed down the central tube by a large quantity of back-water from the washing process, the dilution being assisted by stirring-vanes on the shaft. The fluid stuff is collected in a chest, then passed over sand-tables and through a strainer, from which it flows on to an endless wire-sieve which receives a vertical shaking motion, imparted by ribs on the guide-rolls which are driven at high speed. The fine particles of carbon, clay and fibre-debris are washed through the sieve by means of spray pipes arranged above the travelling wire, so that the stuff is delivered at the other end perfectly washed and practically free from colour. Provision is made for the systematic re-utilisation of the cleaner back-waters. The loss of stuff amounts to 20—30%.—J. F. B.

Manufacture of ethyl alcohol from wood waste. Preliminary experiments on the hydrolysis of white spruce. Kressmann. *See* XVIII.

Patents.

Artificial sponge; Process of manufacturing ——. V. Ottorepetz, Graz, Austria. Eng. Pat. 23,196, Oct. 14, 1913. Under Int. Conv., Oct. 20, 1912.

A concentrated solution of a derivative of cellulose, such as a nitrate or acetate, or viscose, is mixed with fibrous material (cotton, etc.) and a readily soluble substance such as a salt or sugar, and the paste thus obtained is immersed in water or a dilute acid or salt solution, so that pores are formed in the mass owing to the solution of the salts, etc., and the cellulose derivative remains in the form of a spongy body enclosing the fibrous substance.—T. F. B.

Textile plants; Electrolytic and electrochemical process for de-gumming ——. M. S. Peyvel. Fr. Pat. 466,555, March 5, 1913.

The plant, previously steeped in water, is subjected to the action of an electric current in presence of an electrolyte consisting of a solution of caustic soda of suitable strength. —J. F. B.

Cotton waste; Process for cleaning ——. W. Zimmermann. Fr. Pat. 466,806, Nov. 18, 1913.

A mixture of 6 kilos. of fullers' earth with 10 litres of cold water is mixed with a solution of 1 kilo. of potash soap, 1 kilo. of sodium carbonate, and 0·5 kilo. of sodium chloride in 5 litres of boiling water; the whole is boiled and about 250 grms. of "ammonium" are added. The used cotton waste is sprinkled with this solution in a drum fitted with agitators and pressing rolls. The solid impurities collect in a recess at the bottom of the drum; the cleansing liquid is gradually displaced by water and the oily matters floating on the surface of the liquid are drawn off by aspiration through an adjustable pipe passing through the lid.—J. F. B.

Cellulose xanthate; Manufacture of derivatives of ——. F. Petit. First Addition, dated Apr. 4, 1913, to Fr. Pat. 461,900, Nov. 8, 1912 (this J., 1914, 196).

Additional examples of suitable precipitating baths are (1) a 25% solution of common salt with 15% of commercial phosphoric acid, sp. gr. 1·42; (2) a 25% solution of salt with 15% of ammonium chloride and 6% of commercial hydrochloric acid.—J. F. B.

Lustrous threads from crude viscose; Manufacture of —— *by means of a hot mineral acid.* Vereinigte Glanzstoff-Fabriken Act.-Ges. Fr. Pats. 467,164 and 467,165, Jan. 9, 1913. Under Int. Conv, Jan. 10, 1913.

Threads are spun by injecting crude viscose into a coagulating bath containing warm mineral acid only: (1) For viscose which has been ripened for 8 days at 15°—20° C., a coagulating bath containing 20% of sulphuric acid at 40° C. is specified. A normal speed of 40 m. per min. and a normal length of bath of 10—15 cm. are suitable. (2) For viscose in a fresher condition, ripened for about 4 days, corresponding to the stage "C_{12}—C_{18}," a bath containing 10% of sulphuric acid at 25° C. is used; at the normal speed the length of thread immersed in the bath should be about 3 cm.—J. F. B.

Coated sheets; Process of drying ——. G. H. May, Boston, Mass., and W. M. Grosvenor, New York. Eng. Pat. 15,256, July 2, 1913.

Sheets coated with materials combined with volatile solvents, *e.g.*, sheets of waterproofed paper, are dried in a chamber in which the drying medium (*e.g.*, air) is circulated in a closed circuit, the medium being heated to a temperature slightly below the boiling point of the solvent and saturated to the extent of about 60—90% with the vapours of the solvent before coming in contact with the sheets. The evaporation of the solvent is thus controlled and surface-skinning, blistering, etc. are prevented. The closed drying chamber is provided with a condenser maintained at a moderate temperature so that only a determined proportion of the solvent evaporated is condensed, the remainder passing with the air to the re-heater to maintain the partial degree o saturation.—J. F. B.

Paper; Method and apparatus for drying webs of —— C. Bauer, Leipzig-Schleussig, Germany. Eng. Pat. 8607 April 4, 1914.

For completing the drying on both sides of a web o coated paper previously partly dried, the web is conducte by rollers supporting it alternately on opposite side through an annular drying chamber consisting of a hollow cylinder surrounded by a casing, the walls of both bein provided with slots through which heated air is blown o both sides of the paper.—J. F. B.

Paper; Process of sizing ——. Dubois und Kaufmann. Fr. Pat. 467,808, Jan. 28, 1914. Under Int. Conv., Jan. 30, 1913.

Vegetable globulins, dissolved by means of alkalis, ammonia or alkaline-earths, are employed for sizing paper and are fixed by means of aluminium salts or weak acids, or by heating the paper to 60°—120° C. with or without the addition of water.—J. F. B.

Sulphite fibre; Reclaiming waste products [sulphur dioxide] in the manufacture of ——. H. K. Moore and R. B. Wolf, Berlin, N.H. U.S. Pat. 1,103,216, July 14, 1914; date of appl., Nov. 1, 1910.

The contents of the digester are discharged into a blow-pit provided with a vent which maintains the pressure substantially at that of the atmosphere. A surface condenser communicates with the vent, so that the absorption of the sulphur dioxide is limited to that taken up by the liquid products of condensation. The condensed liquid is collected and the excess of sulphur dioxide in the gases passed on for recovery.—J. F. B.

Solutions of cellulose or materials containing cellulose; Process for the production of ——. R. Willstätter, Berlin-Dahlem, Germany. Eng. Pat. 10,605, April 29, 1914. Under Int. Conv., May 24, 1913.

See Ger. Pat. 273,800 of 1913; this J., 1914, 746. Hydrochloric acid containing more than 39% HCl is specified. —T. F. B.

Cellulose; Method of bleaching ——. F. W. Dobson, Tamworth. U.S. Pat. 1,104,109, July 21, 1914. Date of appl., Jan. 26, 1912.

See Eng. Pat. 3181 of 1911; this J., 1912, 225.—T. F. B.

Shaped articles from copper-ammonium cellulose solution; Process for the production of ——. E. Bronnert, Niedermorschweiler, Assignor to Verein. Glanzstoff-Fabriken A.-G., Elberfeld, Germany. U.S. Pat. 1,106,077, Aug. 4, 1914. Date of appl., April 9, 1913.

See Fr. Pat. 454,811 of 1913; this J., 1913, 865.—T. F. B.

Waste water from paper-mills, cellulose factories, and the like; Apparatus for purifying ——. E. Mann and J. Heess, Ebertsheim, Germany. Eng. Pat. 24,938, Nov. 1, 1913.

See Fr. Pat. 464,483 of 1913; this J., 1914, 478.—T. F. B.

Use of chlorophyll extracts as fuel. Fr. Pat. 466,985. *See* IIa.

VI.—BLEACHING; DYEING; PRINTING, FINISHING.

Fibres [bleached cotton]; Causes of discoloration of organic —— *and of articles manufactured from them.* B. Haas. Papierfab., 1914, 12, 891—894.

The tendency to discoloration of bleached cellulose was studied with samples of pure cotton cloth, (a) American, (b), Egyptian. A most useful test consisted in boiling the fabric with distilled water, draining and exposing to light; in many cases the discoloration was already apparent in the aqueous extract. Fabrics bleached with bleaching powder solution showed the greatest tendency to discoloration; those bleached by electrolytic liquor were better and those bleached with sodium peroxide were almost stable in colour. Another test consisted in damping the cellulose and subjecting it in small heaps to a retting process with a thermometer embedded in the heap; lack of purity and tendency to discoloration were then indicated by a greater or less rise of temperature. Unbleached cottons responded to this test in the highest degree but the bleached fabrics also followed in the order of the bleaching processes mentioned above. In all cases the Egyptian samples showed more distinct reactions than the corresponding American samples. The infeiror results obtained with bleaching powder liquor are attributed partly to the deleterious action of the calcium chloride and free lime and partly to the fixation of alkaline-earth compounds on the fibre in an insoluble condition; moreover the benefit to be derived from the use of soft water in the bleaching process is forfeited. In the electrolytic bleach, the sodium chloride and chlorate may have a minor deleterious action, but the fixation of insoluble calcium compounds is avoided. Discoloration is due to the presence of impurities of original or secondary nature, mechanically or chemically combined with the true cellulose, and to the auto-oxidation or alteration of these impurities. The nearec the cellulose approaches a state of complete purity the more stable is the bleached colour.—J. F. B.

Zirconium mordants. P. Wengraf. Färber-Zeit., 1914, **25**, 277—279.

Zirconium was applied to the fibre as the basic acetate and as the bisulphite and its mordanting properties compared with those of an equimolecular quantity of aluminium acetate. Some mordant-dyestuffs were fixed better on zirconium than on aluminium and others the reverse.—J. B.

Aged colours; The diazotisation and development of —— *on the fibre.* M. Freiberger. Färber-Zeit., 1914, 25, 283—284.

Various amines may be oxidised on the fibre like Aniline Black and afterwards diazotised and developed. Fast colours which can be discharged are produced. For instance, Benzidine Puce in this way with various developers gives shades ranging from red-brown to yellow-brown and grey-brown. Xylidine when oxidised on the fibre and developed with resorcinol or α-naphthol gives a bronze, with β-naphthol a dark red-brown, with "Diamine solution" (Cassella) a drab. *o*-Toluidine and dimethylaniline similarly developed give greys. —J. B.

Indigo; Discharge printing on —— *with hydrosulphite and without steaming. Coloured discharge printing with diazo-compounds and vat-dyestuffs.* A. Juteau. Chem.-Zeit., 1914, **38**, 929.

The new indigo-discharge consists in printing a hydrosulphite in an insoluble state—best as zinc salt—and passing through alkali. The paste is prepared directly from sodium hydrosulphite, zinc oxide and zinc chloride. The printed cloth is then treated for 10—15 seconds in a boiling bath containing 10 c.c. of caustic soda of 40° B. (sp. gr. 1·383) per litre, followed by a sodium silicate bath as in the usual process. The caustic soda bath tends to accumulate hydrosulphite and must therefore be frequently renewed. By this method there is no danger of overheating in the drying or re-oxidation, as in the usual method; it is also much cheaper. The paste keeps well and Indanthrene and Algol dyestuffs can be printed along with it as coloured discharges, in which case a caustic soda bath is used as in the ferrous sulphate—stannous chloride process, but weaker. This method of coloured discharge printing can also be combined with the chromate discharge for the purpose of printing diazo-colours. The diazo-colour (nitroanisidine or α-naphthylamine) is printed along with barium chloride. The latter is converted into barium carbonate by passing through boiling sodium carbonate solution, which also removes leuco-indigo. A subsequent bath of bichromate converts the barium carbonate into the chromate. Careful washing and then a bath of oxalic acid and hydrochloric acid follow. The chromic acid liberated, discharges the indigo. The chief difficulty of this method is the careful treatment required on account of the barium carbonate and chromate not being well fixed on the fibre.—J. B.

2-Hydroxy-1-naphthoic acid [*; Use of —— in printing*]. J. Heilmann et Cie. and M. Battegay. Sealed notes 2029, dated Sept. 6, 1910, 2043, dated Oct. 12, 1910, 2045 and 2046, dated Oct. 22, 1910. Report thereon by E. Noelting. Bull. Soc. Ind. Mulhouse, 1914, 84, 267—281.

When diazo-compounds react with 2-hydroxy-1-naphthoic acid combination takes place in the 1-position, the carboxyl group being replaced and products identical with those from β-naphthol produced. Its property of forming stable solutions of the salts without the use of caustic soda and the non-volatility of its salts make the use of this acid of interest in special cases. Thus vat-dyestuffs can be printed on a ground of 2-hydroxy-1-naphthoic acid and fixed by steaming under conditions which would injure a β-naphthol ground on account of dissociation, sublimation, etc. The same applies to printing tannin-colours, which require a good steaming for fixation. The copper and persulphate used in printing Dianisidine Blue easily destroy 2-hydroxy-1-naphthoic acid during steaming, especially in the presence of a little castor oil soap. The rest of the ground can be developed with *p*-nitraniline or, better, with *p*-nitro-*o*-anisidine, the diazonium salt of which is less sensitive to copper. Several recipes show the application of 2-hydroxy-1-naphthoic acid for diazo-colours in conjunction with Aniline Black or basic colours. Additions of antimony salts and (except for α-Naphthylamine Claret) of castor oil soap are generally useful. The acid can also be used in the form of its salts for the production of diazo-colours on wool.—J. B.

Patents.

Ermine; Bleaching ——. A. Gabriel-Claude and H. L. Bricard. Fr. Pat. 467,518, Jan. 21, 1914.

After cleaning (*e.g.* with ether) the skin is impregnated with paraffin, for instance by injecting a solution of paraffin in ether. It is thus protected from the bleaching agent. The hair is then treated with hydrogen peroxide solution followed by hydrosulphite, and rinsed. If a greenish tinge persists, the hair is treated with permanganate followed by hydrosulphite. After soaping and drying, the paraffin is dissolved out of the skin with ether and the latter softened in the usual way.—J. B.

Felt cloth; Process for treating [*sizing*] ——. G. R. Shevill, Brooklyn, N.Y.; M. E. Shevill, Executrix. U.S. Pat. 1,103,694, July 14, 1914; date of appl., Aug. 22, 1912.

Felt cloth and shaped articles thereof are sized with an aqueous solution of gum tragacanth and gum dammar so that the gums become incorporated in and form part of the cloth; bleaching agents, acids and mordants may be added if required.—J. F. B.

Lustre; Production of a fast, silky —— on cotton and other vegetable fabrics. H. Dutschke. Fr. Pat. 467,670, Jan. 24, 1914.

The cloth is impregnated with a salt, *e.g.*, sodium or ammonium chloride, or other crystallisable substance, and calendered at 100°—200° C. The crystallisation of the salt during the hot calendering produces the lustre. —J. B.

Mercerising cotton piece goods and recovering the soda lye used therein; Process of and apparatus for ——. W. Brächter, Lohausen, Germany. Eng. Pat. 25,691, Nov. 10, 1913. Under Int. Conv., Nov. 14, 1912.

See Fr. Pat. 464,730 of 1913; this J., 1914, 480.—T. F. B.

Dyeing furs, hairs, and the like; Process for ——. K. Marx, Dessau, Assignor to Act.-Ges. f. Anilinfabr., Berlin. U.S. Pat. 1,105,447, July 28, 1914. Date of appl., Feb. 21, 1913.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Alkali, etc., works; Fiftieth annual report on —— by the Chief Inspector. Proceedings during the year 1913, *etc.* pp. 151. Price 7½d.

The number of works registered in England, Ireland, and Wales was 1327 (including 70 "alkali" works), and in Scotland 167; this makes a net increase of 23 for the United Kingdom. The increase is again largely associated with the utilisation of by-products, especially ammonia and tar. The acidity of gases of "all chimneys" was equivalent to 1·198 grain SO_3 per cb. ft. as compared with 1·218 grain during 1912, and the further general adoption of mechanical appliances has conduced to the prevention of local intermittent escapes of acid gases and fumes. No occasion for prosecution arose during the year, but in 5 cases back fees for non-registration of processes were accepted in lieu of proceeding being taken.

Alkali and copper (wet process) works. Activity wa maintained throughout the year, the amount of sal decomposed being distinctly greater than during 1912 and a slight but continuous increase is reported in th proportion of hydrochloric acid condensed, as compare with that produced; but the boom in trade of the las two years is considered unlikely to continue in som departments owing to developments in this industr abroad and in the colonies. Means have been taken a St. Helens to neutralise all acid drainage before allowin it to mix with that from the old alkali waste heaps, an the nuisance due to such drainage at Widnes has bee overcome by constructing a special drain around the ol waste heaps. Complaints of escaping acid fumes aros in one case owing to neglect of operatives at the saltcak furnaces to spread a little cold saltcake over the h freshly-drawn charge. A further considerable extensio in the use of mechanical furnaces for calcining burn pyrites in copper works is reported.

Cement works. The emission of black smoke fro rotaries has been much reduced. A steady reduction in t number of vertical kilns, both intermittent and continuo and an increase in the number of horizontal rotary kil continues. *Smelting works.* Further advance w made during 1913 in the prevention of the escape metallic fume and in the reduction of acid escapi with chimney gases, but the acidity of gases from le and copper smelting works presents a problem whi still awaits solution, and the amount of sulphur escaping into the air from the zinc blende calciners in the immediate neighbourhood of Swansea (within an area of 4 sq. miles) is equivalent to approximately 80 tons sulphuric acid of 150 T. (sp. gr. 1·75) per 24 hours. At one large spelter works chambers are being erected for the manufacture of sulphuric acid from the gases, and it is suggested that by calcination in muffle-type furnaces, at a central works, or by arrangement with vitriol makers, the whole of these waste gases might become a source of profit instead of polluting the air.

More attention is now given to providing wider space between sulphuric acid chambers, thus affording greater cooling space and condensing power, longer life to the chambers, greater ease in effecting repairs, and opportunity for keeping the outside of the chambers clean; the practice of limewashing chambers and woodwork is commended as tending to preserve the latter and as making evident the slightest leak. Encasing flues from burners to denitrating columns in cast iron has been found successful in preventing local escapes due to weakening of the brickwork by heat. Appreciative reference is made to an apparatus called "Nitrophor," devised to control automatically the supply of "nitre" to the system by responding to alterations of temperature of the chamber gases, but it is pointed out that influence may be exerted by factors other than the chemical actions taking place in the chambers. Glass-packed absorbing towers are being used in increasing numbers, and water sprays in lieu of steam for supplying moisture to the chambers are on the increase, although in Scotland there is said to be some tendency to return to the older system. The injection of sodium nitrate solution into the first chamber instead of "potting" nitrate in the burner flue, is also becoming popular. In Scotland, fans for controlling draught and additional Gay Lussac towers are in more general use, and a strong solution of soda ash has been employed at several works to reduce obstruction of towers by chemical deposits, with good effect. The undue escapes previously reported during the concentration of acid in over-heat pans were greatly lessened. Kessler plant came into more extended use during the year; the substitution of mechanical means for obtaining the necessary draught further replaced the high-pressure steam jet aspirator originally used in all installations of this form, with advantage as regards steam consumption and strength of recovered weak acid. The cascade system was also further adopted, silica ware, "tantiron," and, to a small extent, "ironac" being in use for making the evaporating vessels.

Chemical manure works were in full activity during the year, the use of mechanical means for removing the freshly manufactured superphosphate from the dens affecting very favourably the general condition of the works. The general average escape of acid gases, equivalent to 0·105 grain SO_3 per cb. ft., is considered satisfactory, being reduced from 0·127 grain for 1912. The quantities of manure materials, expressed in tons, imported into the United Kingdom during the years 1911-13 were:—

	1913.	1912.	1911.
Guano	25,548	14,115	34,124
Mineral phosphates	539,016	520,270	493,413
Nitrate of soda	140,926	123,580	128,487

The imports of mineral phosphates exceed those given in any previous Reports. The exports of ammonium sulphate in 1913 amounted to 325,000 tons, as compared with an estimated home consumption (for all purposes, including manure manufacture) of 97,000 tons. The corresponding figures for 1912 were 287,000 and 90,000 tons. The rapid increase in the manufacture of cyanamide is illustrated by statistics which show a production of 266,000 tons for 1913, as against 152,500 tons for 1912.

Sulphate and muriate of ammonia and gas liquor works continued to increase in number owing, in great measure, to the erection of coke oven works provided with recovery plant for by-products. The amount of ammonia recovered in the United Kingdom (expressed as tons of sulphate) was:—

	1913.	1912.	1911.
Gas works	182,180	172,094	168,783
Iron works	19,956	17,026	20,121
Shale works	63,061	62,207	60,765
Coke oven works	133,816	104,932	105,343
Producer-gas and carbonising works (bone and coal)	33,605	32,019	29,964
Total	432,618	388,308	384,976

In each group of works an increased production over 1912 is recorded. The "direct" method of producing ammonium sulphate and the "semi-direct" method (in which the gases are cooled, to extract tar, and re-heated before passing into sulphuric acid) were put to further service both in coke oven and gas works, and some very high returns of ammonium sulphate per ton of coal carbonised, were claimed as compared with ordinary experience with the distillation method. The fitting of simple but effective systems for continuous liming of stills has extended during the year, with beneficial results on yields, and at two works it has been the practice to decompose cyanides present in the liquor by running down the still a little polysulphide of sodium or calcium with the liquor; this gives an exceedingly white salt. The noxious gases evolved during the distillation continued to be dealt with chiefly by oxide of iron purifiers, and the "heap" form is again reported to be steadily displacing the box or brick walled purifier. The system is useful both in large and small works and for cleaning, and working up to high sulphur content, oxide which has become inert in carburetted water gas purifiers through impregnation with oil; the heat of chemical action taking place in an exposed heap of such contaminated oxide will in time entirely remove the oil by volatilisation. The study of the behaviour of oxide of iron during fouling and revivification (see Reports for 1911 and 1912; this J., 1912, 717; 1913, 787) was continued, with special reference to (*a*) the valuation of oxide as absorbent for hydrogen sulphide, by means of the "sulphuretted hydrogen burette" (*loc. cit.*), (*b*) the part played by ammonia in the foul gases entering the purifier in preventing "souring" of oxide, and (*c*) the temperature attained by oxide purifiers in English and Scottish practice during sulphiding and revivification. Comparative results obtained with the "burette" showed that oxide prepared by drying at 100° C. and remoistening so as to contain 15—20% H_2O is in the best condition for absorbing hydrogen sulphide. In revivifying, the sulphided product was moistened with ammonia water before heating to 40°—50° C. in air, and remoistened as required with the same solution; this prevented a small but distinct loss of sulphur, presumably as sulphur dioxide, as well as formation of free sulphuric acid and soluble sulphate, the sum of the sulphur equivalents of the "free" sulphur, soluble sulphate, and disulphide and other forms found by oxidation with fuming nitric acid being found equal to the sulphur absorbed as hydrogen sulphide. When the degree of hydration was low, a marked increase was observed in the amount of disulphide formed (and subsequently of its oxidation product, ferrous sulphate); a due degree of hydration is therefore considered of the first importance if the efficiency of an oxide is to be maintained. Ignited oxide, although completely sulphided in time, gave a product which re-oxidised very slowly, and the revivified material consisted mainly of the inert disulphide; a significant and discouraging result in view of recent attempts to utilise burnt pyrites and other furnace products for purification purposes. Experiments at both English and Scottish works showed that the average amount of ammonia entering the oxide purifiers with the foul gases was in all cases very small; in the English works however the weight per cb. ft. was nearly 20 times that in the Scottish works. The results so far confirm the conclusion previously arrived at, that the amount of ammonia in the foul gases in Scottish works is insufficient to neutralise acid conditions set up as the result of defective working of the oxide, and are in accordance with Gedel's views (this J., 1905, 664). A very complete study of the working conditions of oxide purifiers has been made in all parts of the country (involving over 220 purifiers) both with respect to the condition of the oxide charged and the maximum temperature attained in the active layer during sulphiding and revivification. The results, given in the form of tables, lead to the conclusions, (1) that in English practice a box or heap purifier, roofed over, is suitable provided care be taken to ensure that the oxide does not get too dry, the heap purifier being preferred for general use, (2) that in Scottish practice the conditions of working are such as to lower the working temperature of the purifier and thereby unduly prolong the "life" of the oxide, giving opportunity for oxidation of the disulphide (a relatively slow process) to soluble sulphate and free acid. The lower working temperature is considered due, in the main, to the small proportion of ammonia and high proportion of carbon dioxide in Scottish gas liquor compared with the sulphide present, but the larger purifying area in Scottish works and, in the north, the lower average atmospheric temperature are contributory causes. It is thought better where possible to seek a remedy for the souring evil by prevention than to apply chemical treatment after the mischief is done (this J., 1913, 787). Where the working temperature is unduly low, the replacing of box by heap purifiers is suggested, or even slight preheating of the saturator gases, after condensation and before admission to the purifier; but the best procedure in cases where souring is a chronic source of trouble is considered to be the use of heap purifiers of small dimensions, with frequent transfer, where possible, of the oxide to the gas works purifiers, where conditions would be suitable for complete sulphiding of the mass, in absence of air. By this means any soluble sulphate present in the oxide would tend to be neutralised by traces of ammonia entering with the crude coal gas and disulphide effectually excluded from contact with air in the surface layers of the material during the sulphiding stage. Laboratory experiments carried out by H. J. Bailey to determine the temperature attained by oxide of iron when fouled with undiluted hydrogen sulphide, in absence of air, and revivified by exposure to air in a thin layer (the processes of sulphiding and revivification being repeated 4 times), showed that an increase in the rate of fouling is attended by a very definite rise of temperature, but that no excessive rise during sulphiding need be apprehended with hydrated oxide suitably moistened, even with the strongest gas; there was no appearance of souring, the increase of soluble sulphate being extremely small. The Claus sulphur recovery process is said to be less popular than it was, partly owing to the comparatively short life of the brick depositing chambers, but partly to the fact that the treatment of large quantities of hydrogen sulphide by oxide purification is so much better understood than formerly. Some few gas works dispose locally of their make of ammonium sulphate but the bulk is sent abroad, although so many of the works are situated in towns surrounded by agricultural districts. Statistics show that whilst in England the consumption of sulphate was only 24% of the product, the United States, France, and Belgium consumed more than they produced, and Germany, with a manufacture of about 500,000 tons, utilised 84% of her output. Five men were gassed (non-fatally) at a coke oven works while repairing a saturator which was blanked off from the foul gas main by a leaden blind slide: physical disconnection of the saturator for such a purpose is regarded as the only safe course.

Fibre separation works. Investigation of a complaint as to a works in the Dewsbury district, for the separation of wool and cotton fibres by means of hot hydrogen chloride gas showed that, although condensation of the acid gases escaping after their employment in the carbonising process was satisfactory, nuisance was liable to arise in removing the carbonised rags from the machine, or by the escape of smoke and steam from the rag-drying plant or accidental firing of dust dropping from the carbonising machines during working. *Tin plate flux works.* Operations were somewhat restricted throughout the year. The average general escape of hydrogen chloride was further reduced to 0·114 grain per cb. ft., from 0·170 in 1912, but it is again pointed out that thorough investigation is needed on the part of manufacturers as to the treatment of scruff and the escaping smoke so as to obtain the best possible yield of valuable material. A plan adopted by many small works consists in giving the whole of the scruff a prolonged washing with boiling water and furnacing the washed material at a very low temperature: short flues suffice, and no wash-tower is necessary. *Venetian red works.* The scrap-iron wash towers, erected in the first instance to prevent pollution of the air by acid gases, continue to give satisfactory results and are now regarded as the cheapest source of the raw material required in the process, at one works more than 40% of the total copperas furnaced being obtained in this manner. *Tar works.* Thirteen new works have been registered. The increase is due chiefly to the extended use of prepared tar for road purposes and to the erection of coke oven works with plant for recovery of by-products. *Zinc residue works.* During 1913 renewed attention was paid to the arresting of fume produced in the condensation of zinc extracted from "residues" containing zinc chloride or zinc and ammonium chlorides. Opportunity was afforded for studying working conditions at 3 works where zinc "ashes" (containing volatile chloride) were in use for spelter making, and tables are given showing the relative fume-arresting efficiency of various types of "prolong," (figured in the Report), both as regards the weights of fume collected and its chemical composition. The prolongs consisted of iron tubes, divided by a bridge into body and end portions; they were attached to certain selected receivers as soon as the "steaming stage" was over, so that the escaping fumes passed through them before being discharged into the air. The condensed fume collected was composed essentially of zinc chloride and metallic zinc or zinc oxide, and consisted of fine dust mixed with "granular" matter (richest in chlorides) and "massive" metal in the form of shot and irregular particles; the weights accumulating in the body and end portions of the prolongs were determined separately and the proportion of zinc and zinc chloride ascertained. Analysis of the material skimmed at the first tapping showed a composition in respect of chlorine content, very similar to that of the fume, but it was contaminated with a large amount of ash and finely divided breeze carried forward from the retorts. The return of fume and skimmings, without treatment, to the furnace with a subsequent charge, as commonly practised, was found to involve an increase of about 25% in the volatile chloride content of the charge, which could readily be prevented by washing the fume and skimmings with cold water. Washing gave a residue very suitable for admixture with a fresh charge and prevented loss of zinc chloride and unnecessary escape of noxious gases, but it is pointed out that in all cases the combustible gases leaving the prolongs should, if possible, be burned. A study of the effect o "breezing-up" receivers showed that when properly worked and carefully fired, a furnace with breezed-up receivers should discharge no more fume than escapes when clay nozzles are in use. Preliminary experiments on the weight of spelter obtained did not support the view advanced by some zinc makers that clay nozzles are less efficient than breeze stoppers in preventing los of zinc.

In Scotland, the number of works registered was on more than in 1912. 63,150 tons of bones and phosphate were dissolved, as compared with 64,242 tons i 1912, and 137,350 tons of pyrites burned, as agains 138,782 tons in 1912. The production of ammoniu salts (expressed as sulphate) and pitch amounted t 125,446 tons and 174,884 tons respectively, the correspond ing figures for 1912 being 120,347 and 151,345 ton Again the shale works have been most busily engage The total shale mined and quarried in Scotland durin 1913 was 3,280,143 tons, as compared with 3,184,826 to in 1912, and the yield of ammonium sulphate, per to of shale, was 43·1 lb., against 43·7 lb. in 1912.—F. SODN.

Sulphuric acid of the I. Oesterreichischen Sodafabrik a K. Opl in Hruschau; The tower system for the manufactu of ——. K. Opl. Chem.-Zeit., 1914, **38**, 8—9.

THE system comprises six towers, through which t sulphurous gases are drawn by means of a suction fa a coke filter at the end of the series serving to retain sulphuric acid mist. The first tower is sprayed with the nitrous-vitriol of the sixth tower, the second tower with that of the fifth, and the third with that of the fourth. Water is introduced into towers 2, 3, and 4, by means of atomisers operating in the roofs. For complete denitration, the acid overflowing from the towers 2 to 6 is reconducted over the first tower. The passage of the acid to and from the towers is effected by emulsifying the liquid with compressed air, the light froth, which is produced, rising to the required height, and reacting rapidly owing to the large surface of liquor exposed. The reaction space is only one-tenth of that required by the chamber system, and the time required for the production of tower acid is only 20 minutes as against 4—6 hours in the case of chamber acid. For making sulphuric acid of 60° B. (sp. gr. 1·71), the consumption of nitric acid of 36° B. (sp. gr. 1·332) is 0·88% of such acid.—O. R.

Sulphuric acid tower processes. G. Schliebs. Chem.-Zeit., 1914, **38**, 966.

THE essentials of sulphuric acid manufacture are: (1), The intimate mixture of the gases; (2), the dissipation of he heat of reaction without the adoption of special neasures; and (3), the production of desired differences f temperature within the reaction space. These requirenents are fulfilled in the chamber process but are lacking n the ordinary tower process. By placing behind each ower an acid separator, capable of circulating the gases ack to the tower, the author claims that all the shortomings of the tower system may be surmounted, and dvantages acquired as regards control and efficiency, nd also economy of nitric oxide.—O. R.

Potassium chloride; Conversion of the mother-liquor from the manufacture of —— into non-deliquescent material. H. Hof. Chem.-Zeit., 1914, **38**, 512—513.

N the German potash industry, by partially evaporating he mother-liquors, which contain magnesium chloride, and ubsequently adding calcined kieserite, epsomite ($MgSO_4$, H_2O) and anhydrous magnesium chloride are formed, nd the mass acquires great hardness.—W. R. S.

odium silicates; Crystallised ——. E. Jordis. Chem.-Zeit., 1914, **38**, 922. (See also this J., 1914, 253.)

YNTHETIC and technical preparations of the silicates, a_2SiO_3,nH_2O, examined by dilatometric, tensimetric, nd thermometric methods, gave curves with haltingoints at 31°, 37·2°, 41·9°, 46·9°, 47·2°, and 62·3° C. The mperatures 62·3°, 47·2°, and 37·2° C. are the melting oints of hydrates with 6, 9, and about $10H_2O$, whilst 1·9° and 31° C. are the eutectic points of mixtures of the ydrates with 6 and $9H_2O$ and with 9 and about $10H_2O$ spectively; the readings 46·9° and 47·2° C. possibly refer the same compound. The various hydrates showed a ndency to decompose into mixtures of relatively more d less hydrated forms, and prolonged heating at 100° C. elded a product containing about $1·5H_2O$. The hexad nona-hydrates are described, but higher hydrates ere not isolated.—F. SODN.

organic syntheses [of silicates, aluminates, stannates, ferrites, chromites, manganites, titanates, and zirconates]. W. Pukall. Silikat-Zeits., 1914, **2**, 65—76, 87—99, 109—118.

LICATES were prepared (*a*) by interaction of pure alkali icates and metallic salts, in dilute aqueous solution, d (*b*) by prolonged heating of silicic acid with metallic ides, carbonates, or nitrates, at relatively low temperares. Potassium meta-, di-, tri-, tetra-, penta-, and xa-silicates, prepared by heating silica with potassium carbonate, were clear glasses, soluble in water; the rresponding sodium salts tended to crystallise and were s soluble (compare G. W. Morey; this J., 1914, 253). ethod *a* was applied to the preparation of numerous eta-silicates (see this J., 1910, 1011) and of lcium and ferrous disilicates (using potassium disilicate as precipitant). Aluminium chloride and alkali disilicate yielded, according to the conditions, either $6SiO_2,Al_2O_3,3H_2O$ or double silicates of aluminium with potassium or sodium, one of which corresponded in composition to a hydrated form of orthoclase. Calcium ortho- and di-silicates were prepared by the action of silicic acid on lime at the ordinary temperature, and aluminium hydroxide gave with lime, in the presence of water, a series of crystallised calcium aluminates, of which five are regarded as individuals; a second form of the tricalcium salt was obtained by heating on the water-bath. In method *b*, the materials were very intimately mixed and repeatedly ignited at 950° C. (and if necessary at 1270° or 1370° C.) until reaction was complete, the temperature of ignition being as a rule below the melting-point of the product. Ortho- and meta-silicates of Li, Ba, Sr, Ca, Mg, Be, Fe'', Mn, Co, Ni, Zn, Cd, and Pb were thus prepared and (using appropriate oxides or salts) ortho- and meta-stannates of Li, Ba, Sr, Ca, Mg, Be, Zn, Cd, and Pb, aluminates of types, RO,Al_2O_3, and $2RO,Al_2O_3$, of Ba, Sr, Ca, Mg, Fe'', and Mn, aluminates of type, $3RO,Al_2O_3$, of Ba, Sr, Ca, Fe'', and Mn, the ferrites, $CaFe_2O_4$, $Ca_2Fe_2O_5$, $Ca_3Fe_2O_6$, and $Ca_4Fe_2O_7$, calcium chromite, $Ca_4Cr_2O_7$, and ortho- and meta-titanates and zirconates of most of the above metals. In all cases, the microscopical appearance of the product and its behaviour towards dilute hydrochloric acid is described. Ortho-silicates, stannates, titanates, and zirconates were, as a rule, obtained more readily than the corresponding meta-salts. Both ortho- and meta-silicates of calcium exhibited hydraulic properties (the latter only in the presence of a strong base), but both were converted by further ignition into inactive β-modifications. The calcium aluminates prepared were all hydraulic, the speed of setting increasing with the proportion of calcium present; mortar made from the tri- and tetra-salts disintegrated. Powerful hydraulic properties were also possessed by the alkaline-earth orthostannates and by tetra-calcium ferrite ($Ca_4Fe_2O_7$) and the corresponding chromite, both of which gave a quick-setting mortar, disintegrating in the case of the ferrite. The hydrated calcium aluminates showed a plasticity little inferior to that of kaolin.—F. SODN.

Magnesia in magnesites; Determination of ——. H. Wdowiszewski. Chem.-Zeit., 1914, **38**, 949—950.

MAYERHOFER'S method (Z. angew. Chem., 1908, **21**, 592) has been found inaccurate, but gives good results when carried out in the following manner: 5 grms. of magnesite are decomposed by heating with *aqua regia* on the water-bath, the solution is evaporated to dryness, the residue heated for half-an-hour at 180°—200° C., treated with hydrochloric acid on the water-bath, filtered from silica, and made up to one litre. Forty c.c. of the solution (or 20 c.c. with burnt magnesite) are treated with 5 c.c. of strong sulphuric acid and 100 c.c. of ammonium citrate solution (100 grms. of citric acid and 333 c.c. of ammonia, of sp. gr. 0·91, to 1 litre), cooled to 1°—2° C., further treated with 20 c.c. of 10% sodium phosphate solution and 15 c.c. of strong ammonia, the mixture shaken vigorously for 5 minutes, and allowed to stand for 2 hours in ice-water; the precipitate is filtered off, washed with dilute ammonia (1 : 3), and dissolved in hydrochloric acid, the solution again precipitated with ammonia, allowed to stand for half-an-hour in ice-water, the mixture shaken for 5 minutes, filtered, and the precipitate washed with ammonia, dried, ignited, and weighed as $Mg_2P_2O_7$. —F. SODN.

Rare earths; Salts of the —— with hydroxydicarboxylic acids. G. Jantsch. Chem.-Zeit., 1914, **38**, 794. (See also this J., 1913, 140.)

SALTS of the rare earths with malic acid have been prepared in two different hydrated forms.

$$Me_2(C_4H_4O_5)_3.8H_2O(9H_2O) \text{ and } Me_2(C_4H_4O_5)_3.6H_2O(7H_2O).$$

They are soluble in presence of excess of malic acid or an alkali malate, and from these solutions alcohol precipitates crystalline complex salts of the types $Me(C_4H_4O_5)_2H,xH_2O$, $Me(C_4H_4O_5)_2R,H_2O$, or $Me(C_4H_4O_5)_3R_3,xH_2O$. ("Me" stands for "rare earth metal.") From solutions of these complex salts, ammonia did not give an immediate precipitate of the hydroxide, and electrical conductivity measurements confirmed their complex character.—G.F.M.

Radium; Technology of the extraction and utilisation of ——. R. Sternlicht. Chem.-Zeit., 1914, **38**, 49.

The working of pitchblende (average uranium content, 45%) at the Austrian State radium factory, Joachimsthal, by the Curie-Debierne method gives at most 80% of the radium present, and, at the French factory of Armet de Lisle, uranium mica, uranium ochre, carnotite, and autunite, in part decomposed directly with hydrochloric acid, yield about 70% of their radium content. Ebler's method of reduction with calcium hydride (this J., 1913, 976) is criticised on the ground of expense and because loss of radium is liable to occur through re-oxidation of sulphide to sulphate. The Ulzer-Sommer method (this J., 1910, 1156) gives yields of 97—98% and has been carried out on the large scale. The separation of radium and barium is usually effected by fractional crystallisation; Ebler's adsorption method (this J., 1913, 1154) is said to be little used at present. The total world's output of radium (mostly employed in making pharmaceutical preparations and radiation apparatus) is estimated at 7—8 grms. per annum.—F. Sodn.

Radio-elements in rocks; Distribution of ——. *I. Monazite sand.* M. Baltuch and G. Weissenberger. Z. anorg. Chem., 1914, **88**, 88—102.

Determinations of radium and thorium in the constituent minerals of monazite sand (from Brazil), which were separated partly by magnetic concentration and partly by the specific gravity method and then purified by chemical treatment, gave the following results:—

	Percentage in sand.	Radium, per 1 grm. of sand.	Thorium, per 1 grm. of sand.
		grm.	grm.
Monazite	74·95	$1{\cdot}54, 10^{-10}$	$4{\cdot}19, 10^{-2}$
Zircon	8·84	$7{\cdot}88, 10^{-12}$	$1{\cdot}19, 10^{-5}$
Ilmenite	12·36	$3{\cdot}60, 10^{-12}$	$4{\cdot}02, 10^{-5}$
Magnetite ..	0·47	$1{\cdot}54, 10^{-13}$	$2{\cdot}29, 10^{-7}$
Quartz	3·02	$1{\cdot}66, 10^{-14}$	$3{\cdot}53, 10^{-8}$
Felspar	0·29	$2{\cdot}24, 10^{-15}$	$4{\cdot}39, 10^{-9}$

Uranium (0·062%) was found in the monazite, and the ratio Ra/U harmonised with the results of Boltwood and Rutherford for uranium minerals. The zircon crystals exhibited a violet colour like that of glass after exposure to radium preparations.—F. Sodn.

Patents.

Hydrochloric acid: Process of producing ——. J. H. Nield, Hackensack, N.J., Assignor to General Chemical Co., New York. U.S. Pat. 1,102,539, July 7, 1914; date of appl., Aug. 21, 1909.

Sulphuric acid is heated with common salt and an amount of substantially inert material (*e.g.*, an equal weight of saltcake) sufficient to prevent the formation of a pasty mass at any stage of the process.—F. Sodn.

Oxidation process [*for making sulphuric acid*]. C. Ellis, Montclair, N.J., Assignor to Ellis-Foster Co., and C. L. Parsons, Washington, D.C. U.S. Pat. 1,103,017, July 7, 1914; date of appl., Sept. 16, 1912.

The oxidation of sulphur dioxide is effected by means of a substantially metalloidal catalyst, preferably by bringing a mixture of sulphur dioxide, oxygen, and water vapour into contact with heated material containing tellurium and traces of a selenium activator. The gases require only to be rendered free from dust, since the contact material is not appreciably affected by small quantities of bodies toxic to metallic catalysts.—F. Sodn.

Sulphuric acid; Manufacture of ——. U. Wedge, Ardmore, Pa. U.S. Pat. 1,104,590, July 21, 1914; date of appl., Sept. 18, 1909.

The gases leaving the Glover tower pass first through a number of tower-like lead chambers, connected in series alternately at the top and bottom, and presenting a surface area of 0·3 sq. ft. or more per 1 cb. ft. of chamber space, and then through a number of lead chambers presenting a much smaller area of surface per unit of cubic capacity. —A. S.

Nitrogen; Process and apparatus for fixing atmospheri ——. W. S. Landis, Niagara Falls, N.Y., Assignor t American Cyanamid Co., Nashville, Tenn. U.S. Pats 1,103,060, 1,103,061, and 1,103,062, July 14, 1914; dat of appl., April 3, 1914.

(1). An inner perforated vessel containing carbide i mounted within an outer vessel. The inner vessel has lining of porous fabric to prevent carbide passing ou through the perforations. Nitrogen is supplied to th carbide through the perforations, and the charge is heate electrically at one part to the point of ignition by mea of a resistor embedded in the charge. (2). Several resisto are embedded in the charge of carbide, and their expose upper portions are enlarged to prevent destruction l oxidation. (3). The resistor is embedded in the charge o of direct contact with the excess of nitrogen circulati through the charge. The resistor is heated to a temperatu sufficient to cause the desired reaction, and, in addition, he is supplied continuously to the charge, from an outsi source, during the process.—A. S.

Chromic salts; Production of ——. Badische Anilin u Soda Fabrik. Fr. Pat. 466,478, Dec. 22, 1913. Und Int. Conv., Feb. 1, 1913.

An oxide mineral, *e.g.*, chrome iron ore, is treated w chlorine or hydrogen chloride at a high temperature, the presence of a reducing agent, such as carbon or carb monoxide, and the more volatile ferrous or ferric chlor produced is collected separately from the less volat chlorides of chromium. The product is sufficiently p for industrial purposes.—F. Sodn.

Radio-active; Process for rendering liquid or gase substances —— *and activating substances for carrying the process.* J. Landin. Fr. Pat. 466,850, Dec. 1913. Under Int. Conv., Feb. 10 and April 11, 1913

Liquid or gas to be activated is treated with a radioact substance producing emanations (*e.g.*, a radium sa enclosed in an inert protective medium, such as para paraffin oil, or wax, which dissolves and transmits emanation. Zinc sulphide or other material rend fluorescent by the radiations may be incorporated with activating substance.—F. Sodn.

Radium and mesothorium; Process for the treatmen minerals and intermediate products containing ——. Ebler. Fr. Pat. 467,330, Jan. 15, 1914. Under Conv., Sept. 17, 1913.

Material containing radium or mesothorium in the of sulphate is intimately mixed with calcium carbid substances producing such (4 mols. for each mol. of sulpl and heated to bright redness, the product being extra with a feebly acid solution, preferably hydrochloric so as to give a solution of crude chlorides (see this J., 1913, 867). The reduction, which is very complete, may be rendered "autogenous" by mixing the carbide with calcium hydride or other substance reacting suitably with the sulphates present or added.—F. Sodn.

Alkalis present in a combined state in natural double silicates ; Process for the extraction, in a soluble form, of ——. R. van der Leeden. Fr. Pat. 466,952, Jan. 2, 1914.

The material is treated with an equal or smaller proportion of alkaline-earth chloride, or mixture of alkaline-earth oxides, in presence, if necessary, of a reducing agent such as carbon, and the product extracted with water. The process is specially applicable to the extraction of potassium salts from leucite-phonolite, furnishing a residue suitable for cement making.—F. Sodn.

Halogen compounds of alkalis, aluminium, silicon, titanium, and other bases ; Process for obtaining —— from natural double silicates. R. van der Leeden. Ger. Pat. 267,867, Jan. 4, 1913.

Natural double silicates, such as leucite, nepheline, muscovite, orthoclose, etc., are heated to a high temperaure, alone or mixed with reducing agents, in an atmosphere l chlorine, bromine, or iodine. The halogenides produced re recovered by sublimation or distillation. When hlorides are obtained by this process they are preferably lectrolysed to yield chlorine for the decomposition of a rther quantity of the silicate.—A. S.

ium nitrate and other salts ; Process for reducing —— a finely divided state without the formation of dust. Norsk Hydro-Elektrisk Kvaelstofaktieselskab. Fr. Pat. 466,963, Jan. 3, 1914. Under Int. Conv., Jan 17, 1913.

he molten substance is formed into globules and allowed o fall freely in a gaseous atmosphere, such as air, which may be circulated in the opposite direction and submitted o cooling. Powdered material may be added to the nelt immediately before granulating.—F. Sodn.

luminium nitride ; Process of decomposition of ——. G. Coutagne. Fr. Pat. 466,986, March 19, 1913.

n intimate mixture of aluminium nitride and caustic kali, alkaline-earth oxide, or mixture yielding such, is eated above 200° C., at atmospheric pressure, in presence f steam, preferably in a horizontal or slightly inclined steel ube which may be heated to about 300° C. and slowly tated. A series of fixed scrapers operate against the ner wall of the tube to detach adhering material, which then crushed by steel balls or the like present in the wer part, and a little water or steam may be injected gainst the wall or scrapers as required. The aluminate roduced is suitable for the production of alumina, whilst e liberated ammonia is preferably mixed with carbon xide and made to react with calcium sulphate in known anner to produce ammonium sulphate.—F. Sodn.

luminate-silicates allowing of the ready passage of liquids ; Manufacture of granular or laminated ——. Permutit Aktienges. Fr. Pat. 467,038, Jan. 6, 1914. Under Int. Conv., Jan. 6, 1913.

d silicates containing alumina, after preliminary treatent with common salt solution to remove alkaline-earth etals, are digested with a strong solution of alkali silicate.
—F. Sodn.

phurous acid [e.g. hydrosulphites, etc.] : Manufacture reduction products of ——. Chem. Fabr. Griesheim Elektron. Fr. Pat. 467,443, Jan. 17, 1914. Under Int. Conv., May 2, 1913.

e reduction of sulphurous acid or its salts is effected means of spongy zinc, obtained by electrolysis, which likewise employed, without addition, for the conversion alkali formaldehyde bisulphite or hydrosulphite into phoxylate.—F. Sodn

Sulphuric acid ; High concentration of ——. A. Zanner, Laeken, Belgium. Eng. Pat. 19,481, Aug. 28, 1913. Under Int. Conv., Aug. 30, 1912.

See Ger. Pat. 260,655 of 1912 ; this J., 1913, 751.—T. F. B.

Ammonia ; Process of producing ——. P. A. Newton, London. From Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. Eng. Pat. 16,903, July 23, 1913.

See Fr. Pat. 460,859 of 1913 ; this J., 1914, 76.—T. F. B.

Ammonia from moist waste substances or peat ; Process and apparatus for obtaining ——. E. Stauber, Berlin, and W. Kochan, Charlottenburg, Germany. Eng. Pat. 41, Jan. 1, 1914.

VIII.—GLASS ; CERAMICS.

Glass and fused silica ; Note on the resistivities of —— at high temperatures. A. Campbell. Proc. Phys. Soc. London, 1913, **25**, Part V. Nat. Phys. Lab., Collected Researches, 1914, **11**, 205—208.

THE tests were made on tubes about 30 cm. long, 1—4 cm. diam., and with walls 0·05—0·12 cm. thick. The voltage was either 200 or 500, and the time of electrification 1 min. With fused silica having a silky surface the resistivity in megohm-cm. was over 200,000,000 at 15° and 150° C., but fell to 20,000,000 at 230°, 2,500,000 at 250°, 200,000 at 300°, 30,000 at 350°, 800 at 450°, 30 at 700° and about 20 at 800° and 850° C. The values for different glasses were :—ordinary (soda lime) glass, 500,000 at 18° and 100 at 145° C., " Geräte " (zinc-aluminium) glass, 3,000,000 at 18° C., Jena glass (combustion tubing), over 200,000,000 at 18°, 36,000,000 at 115°, 18,000,000 at 150°, 0·01 to 0·04 at 750° C. (with 2 volts the apparent resistance rose quickly from 150 to 609 ohms owing to polarisation). The resistance of sheet mica (0·026 mm. thick) was over 300,000,000 megohms at 18° and 135° C. ; it was reduced considerably at higher temperatures but not so much as in the case of glass and fused silica.—A. S.

IX.—BUILDING MATERIALS.

Wood preservation with substances soluble in water. B. Malenkovic. Z. angew. Chem., 1914, **27**, Aufsatzteil, 132—135.

THE treatment of wood with zinc chloride, copper sulphate, and even, on account of its high price, with mercuric chloride, is being superseded. Whilst the author's method of using zinc and sodium fluorides, or a mixture of 88·89% of sodium fluoride with 11·11% of the anilin salt of dinitrophenol (Basilit or Bellit) has given results in some cases equal to those obtained with tar-oil, th method must be properly used, and even then sometimes fails to reach the standard of " antiseptic power," $a=16$, which the author regards as requisite ; ($a=\frac{z}{p}$, in which z is the number of kilos. of antiseptic absorbed by 1 cub. m. of wood, and p the number of grms. required to keep 100 c.c. of culture medium, gelatin or agar, free from *penicillium*). For this purpose other substances, cheaper and more soluble, alone or in admixture with existing substances, are required.—O. E. M.

" Mammoth " pumps and sludge elevators for mixing an transporting slurry. Steen. Chem.-Zeit., 1914, 33 590.

THE stirring effected by these pumps (this J., 1914, 301 is so vigorous that slurry left standing for days is ready fo use soon after starting the pump, and considerable savin is effected, since constantly running stirrers are no necessary. The air lift pump is suitable for moderat lifts ; the elevator, which will deal with large stones is not thus limited. It consists of a large vesse suitably connected, into which the slurry is first drawn b suction, and from which it is then expelled by compresse air. The valves are automatically controlled by the liqui Three cub. m. of slurry are raised 15 m. in 3 minut by an expenditure of 23 amp. at 500 volts. The elevat is capable of transporting slurry varying widely in co sistency.—O. E. M.

PATENTS.

Roofing-compositions [; Elastic fire-resisting ——]. E. White, Terenure, Ireland. Eng. Pat. 1805, Jan. 1914.

MELTED natural bitumen (1 part by vol.) is added t parts of calcined pure silica sand, both at 200° C., a with these are incorporated 10% by weight of lead ox and 10% of mixed alkali silicates (at 160° C.). T silicates are prepared by melting together finely grou silica sand 100 parts, potash 29, calcined ball soda and ground wood charcoal 9 parts, and boiling till mass is of a gelatinous consistence. The composit is spread as a layer (at least ¼ inch thick) on a foundat of felt or the like (preferably " Ruberoid ").—F. Sod

Wood ; Preservation of ——. R. A. Marr, Ghent, U.S.A. Eng. Pat. 2084, Jan. 26, 1914.

WOOD is immersed in an open bath containing a volatile material insoluble in water, and of m. pt. not 212° F. (100° C.), a somewhat volatile aromatic hy carbon, and a solid material so finely divided as t carried into the pores and ducts of the wood and sufficie hard to render it insect-proof. A suitable composi is paraffin wax 100, naphthalene 5—15, and diatomae earth 2—5 parts. Paris green or other solid insect may be used in addition to or instead of the diatomac earth. The bath should be maintained at 212° to a 240° F. (100°—116° C.), but a second treatment lower temperature may be given to secure supersatura Impregnation is complete even with green wood ha the bark intact.—F. SODN.

Impregnating wood and other porous materials under pressure; Apparatus for ——. P. F. Berk, London. From F. Moll, Berlin, and A. Kossel, Marktredwitz, Germany. Eng. Pat. 25,682, Nov. 10, 1913.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Pig iron; Increase of the strength of iron obtained by the use of German —— low in carbon. A. Geissel. Stahl u. Eisen, 1914, **34**, 1291—1294.

Mechanical tests made on a number of bars cast from iron improved by addition of low-carbon pig iron of German production, showed an ncrease of strength of about one-fourth with 15% of the low-carbon ron, and a correspondingly greater ncrease with larger additions.—T. St.

Welds; Oxy-acetylene ——. *Experiments on their strength.* A. Campion and W. C. Grey. Times Eng. Suppl., July 31, 1914, 81.

Tensile tests, after various treatnents, on welded mild steel bars with about 0·25%, turned so that the racture would take place at the weld, howed considerable differences in the nean results of each treatment and n individual bars of each set. The veld had an average about four-fifths f the strength and one-fifth of the uctility of the unwelded steel, and ts ductility could not be made to pproach that of the unwelded portion. Repeated mpact tests made in the Stanton machine, the bars otched in the centre of the welded portion, also gave ery variable results. Hammering was the most effective reatment for increasing the fatigue-resisting properties f the material, but this should be done with the metal t a full red heat (800° C.) to remove strains and brittleness hich might result from hammering the comparatively ool metal near the weld. Reheating and annealing alone id not increase the fatigue-resistance of the welded ortion. The form of treatment which gave the highest trength in tension gave the lowest results in impact sts. To test the weld with reference to the over-heated ne immediately adjacent, another set of impact tests was nade on bars notched at the edge of the weld. The ariations in the energy of fracture were here even greater han in the first set, but reheating to 800° C. very nearly stored the material to its original strength. Results f repeated-impact tests on plates of different thickness howed very clearly that the thicker the plate the less liable was the weld, and the greater the reduction in rength. Autogenous welds must always be regarded s somewhat uncertain, there being no means, except y destruction tests, of ascertaining whether a weld good or bad; they should therefore be accepted with xtreme caution, if not entirely prohibited, in cases here failure would tend to endanger life or limb.

—T. St.

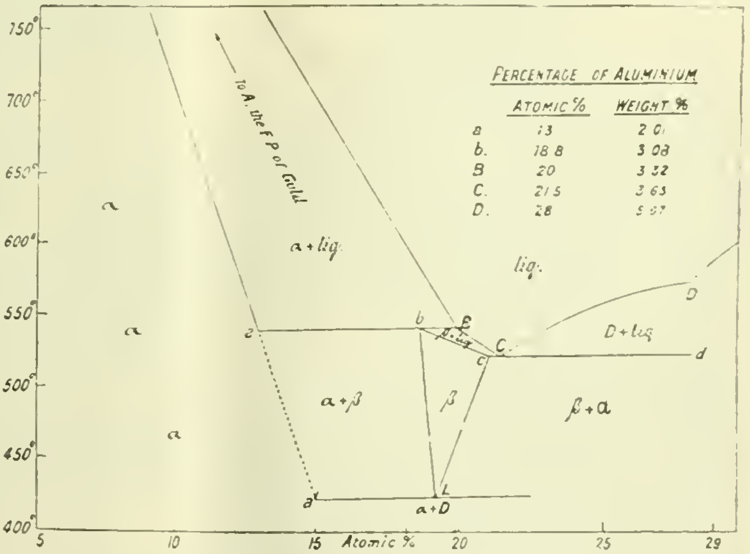
Blast-furnace for smelting [copper-bearing] concentrates. E. W. Honeyman. Eng. and Min. J., 1914, **98**, 199—201.

A furnace is described for smelting 440 tons per day of copper-bearing concentrates such as are usually treated in a reverberatory furnace. The blast furnace is 44 in. wide at the tuyères and 33 ft. long, and is worked with a blast of 20,000 cb. ft. of air per min. at 14 oz. pressure. It is constructed of single-tier water jackets, arranged one at each end and 11 along each of the longer sides. Three 4½ in. tuyères are provided in each side jacket. The upper part of the furnace structure is formed by a series of air jackets suspended from a separate frame, and the top is of gable form with 4 uptakes, 5 ft. in diameter. The paper includes detailed drawings with dimensions.—A. T. L.

Aluminium in gold; Dilute solutions of —— C. T. Heycock and F. H. Neville. Roy. Soc. Proc., 1914, A, **90**, 560—562.

The solid condition of gold containing up to 5% by weight (28 atomic per cent.) of aluminium is shown in the figure. Gold can dissolve up to about 2% of its weight of aluminium to form a uniform solid solution *a*. With rather more aluminium a new constituent β, which can also vary somewhat in composition, appears side by side with the *a*. Next the *a* disappears and with a further rise in the percentage of aluminium a new constituent D, probably Al_2Au_5 appears. The solid β may be regarded as a solvent for *a* and D. When the representative point passes by cooling out of the triangle b L c (see fig.), *a* or D crystallises from the previously uniform alloy and finally when the slowly cooled alloy passes below 424° C. the β phase breaks up to a "pearlite" complex of *a* and D. If cooled further, alloys with between 2 and 5% Al show a remarkable recalescence not indicated in the diagram. The *a* and D of the eutectoid apparently react forming a new and stable substance which the authors believe to be the definite compound Au_4Al.

—W. H. P.



Gun-metal; Mechanical properties of ——. *Influence of temperature.* J. C. Longbottom and A. Campion. Times Eng. Suppl., July 31, 1914, 81.

Admiralty gun-metal (Cu 88, Sn 10, Zn 2%) was tested mechanically at temperatures up to 750° C. The strength and modulus of elasticity remained fairly uniform up to about 200° C., and then fell. The ultimate elongation reached a maximum at 140° C. and fell to less than 1·5% at 350° C. The critical temperatures could not be associated with phase changes of the alloy, and it is considered that the results furnish strong evidence for the existence of some form of cement between the crystal boundaries of the metal, upon which the strength and other properties are largely dependent. The amorphous cement appears to lose its ductility at a lower temperature than that at which it loses its strength.—T. St.

Solution of metals in acids. A. Thiel. Z. Elektrochem., 1914, **20**, 460—463.

Commenting on the paper of Centnerszwer and Sachs (this J., 1914, 753), the author points out that the more modern data on the overvoltage of hydrogen at metallic surfaces, do not support the view that it is simply related to the solution tension of the metal. The use of the term "passivity" to describe the condition of slowly dissolving zinc is criticised as the retarding influences at work are probably mainly due to the state of the surface and to variations in the overvoltage, and not to passivity as that term is usually understood. It is also argued that the difference of potential of "local elements" in an impure metal is consequent on and not the cause of the discharge of hydrogen ions. The phenomena of solution will probably be most satisfactorily elucidated by a study of the magnitude of the surface, of the effect of foreign metals on the overvoltage and of capillary data.—W. H. P.

Cathodic spattering [*of metals*]. G. W. C. Kaye. Proc. Phys. Soc. London, 1913, **25**, Part III. Nat. Phys. Lab., Collected Researches, 1914, **11**, 191—196.

Cathodic spattering, observed when a current is sent through a discharge tube at low pressures, and resulting in the deposition of metal on the glass adjacent to the cathode, has proved very useful as a means of preparing films and mirrors, especially in the case of metals intractable by the usual methods. The spattered metal is expelled from the cathode as minute particles, apparently of the same order of magnitude as those present in colloidal solutions; they settle only on surfaces positive with respect to the cathode and in practice the surface to be coated is connected with the anode. Apart from certain exceptions the amount of spattering is roughly proportional to the chemical equivalent of the metal. The effect is usually marked with palladium, platinum, gold, silver, copper, cadmium, and tin, but is small in the case of aluminium and iron in air. With cadmium and zinc the effect is greatly increased by rise of temperature of the cathode. The amount of spattering is roughly proportional to the square of the current density and is increased by increasing the potential drop at the cathode, *e.g.* by diminishing the pressure of the gas in the tube. Hydrogen, nitrogen and carbon dioxide act unfavourably. Mercury vapour, oxygen, and more especially the monatomic gases, helium, neon, argon, krypton, and xenon bring about marked spattering of nearly all metals, argon being particularly effective. The appearance and properties of the deposit depend upon the nature of the gas. The spattering is usually confined mainly to points and edges of the cathode, where the potential gradient attains a maximum; and it is suggested that the blackening of X-ray tubes might be largely prevented by constructing the cathode wholly free from sharp edges and the anticathode of approximately spherical shape.—A. S.

Colloidal gold solutions; Reactions in the preparation of —— by the formaldehyde method, and the influence of carbonic acid on the formation of these solutions. W. v. Naumoff. Z. anorg. Chem., 1914, **88**, 38—48.

The preparation of colloidal gold solutions by Zsigmondy's method (this J., 1898, 767) is considered to involve the intermediate production of gold hydroxide and potassium aurate. Deep red stable solutions were prepared by direct reduction of the latter compound, the reaction being

$$2AuO_2K + 3H.CHO + K_2CO_3 = 2Au + 3HCO_2K + KHCO_3 + H_2O.$$

Carbon dioxide, in sufficient quantity, completely prevented the formation of colloidal solutions, but by boiling for 5—10 mins. before reduction, satisfactory results were obtained even cold, in presence of added nuclei (see Z. physik. Chem., 1906, **56**, 65; 1909, **66**, 129).—F. Sodn.

French electrochemical and electrometallurgical industries. For. Off. Ann. Ser. No. 5324. [T.R.]

A large company hitherto engaged in the manufacture of paper and sodium at Rioupéroux in the valley of the Romanche (Isère), from whose waters it derives its power, has given up these branches of industry as the result of a law suit, and has embarked instead on the manufacture of ferro-alloys and calcium carbide. The French syndicate controlling the manufacture of the latter product has recently made a substantial reduction in its price, with a view to combating competition.

The company working the Paul Girod patents for the manufacture of special steels and ferro-alloys at Ugines (Savoie) and elsewhere, has lately acquired further works and water-power on the Bon Nant near St. Gervais-les-Bains. In future the manufacture of ferro-alloys will be confined to the Ugines works of the company, while that of calcium carbide will be carried on at their works in Switzerland. Licences have been granted for working the Paul Girod processes to the Bethlehem steel works of America, and the French company is at present engaged in mounting extensive plant in the Ansaldo-Armstrong works in Italy and the Putiloff works in Russia. The two Paul Girod companies—for ferro-alloys and electric steels respectively—have lately reorganised their finances by means of a drastic reduction of capital.

Large hydro-electric works are about to be erected at Laroquebrou (Cantal) for the production of nitrate of soda in the electric furnace. The motive power will be furnished by means of a dam to be built across the Cère, causing a waterfall 488 ft. high. The cost of this enterprise is estimated at £800,000. Another works for the manufacture of artificial nitrates is in contemplation at Bouvillard, near Aiguebelle (Savoie), with power derived from the Arc at La Chambre. The manufacture of electrodes is actively carried on in the works of the Electrode Company situated at Venissioux on the outskirts of Lyons, whose output exceeded 5,000 tons in 1913. Up to the present time no nitrides have been produced by the Société Générale des Nitrures at their works at St. Jean de Maurienne. Arrangements are said to have been concluded with a Norwegian concern with works at Arendal (25,000 H.P.) for the production of nitrides on account of the French company for importation into France—this move being explained as necessitated by the lack of sufficient power in the St. Jean de Maurienne works. Another company is at present engaged in perfecting a rival process the invention of Coutagne.

Patents.

Pig iron; Manufacture of ——. C. A. Keller, Pat Eng. Pat. 22,692, Oct. 8, 1913.

Scrap iron or steel is melted in an arc electric furna with suitable slags, and the desired amount of carb added. Other elements may be added in the form ferro-alloys, or as oxides with the carbon necessary their reduction. Dephosphorisation and desulphurisati are effected with an oxidising basic calcium slag and wh dephosphorisation is complete, finely divided coal introduced into the body of the metal, convenient through a hollow electrode, and the metal is then trai ferred to a second electric furnace where it is desulphurised by a non-oxidising calcium slag. Alternatively, the carbon for carburising the metal may be placed at the bottom of the second furnace. To obtain a metal with low silicon and high carbon content a slag containing a minimum amount of silica or other easily reducible oxide is employed in the smallest amount required for purification.—T. St.

Steel : Apparatus for manufacturing ——. G. H. Benjamin, New York. U.S. Pat. 1,102,382, July 7, 1914 ; date of appl., Nov. 7, 1913.

The plant consists of a mixer, movable tilting hearths running on two circular trackways which intersect, and a ladle for the refined metal. Hoods, movable vertically, occupy fixed positions on the trackways for use with the hearths. Some of the hearths are heated by gas, the others electrically.—T. St.

Ore separating and the like ; Process and apparatus for hydraulic jigging. ——. K. Kleinberg, Libuschin, Austria. Eng. Pat. 13,191, June 6, 1913.

The pressure of the air contained above the water is regulated in chambers distributed over the jig sieve, the regulation of the compression corresponding to the up-lift being effected independently of the rarefaction due to the descent of the water.—W. R. S.

Ores ; Concentration of ——. Minerals Separation Ltd., London. From T. M. Owen, Broken Hill, N.S.W. Eng. Pat. 16,141, July 12, 1913.

Complex sulphide (galena and blende) slimes are first agitated with a limited amount of air and a minute quantity of eucalyptus oil (1 oz. per ton of ore) at the ordinary temperature without the addition of acid. The greater proportion of the galena having been thus removed in the froth, the pulp is treated with a further addition of oil and increased air supply, and, if desired, with acid, to recover the blende. A preliminary flotation separation may be made without the addition of a frothing agent but with the use of an acidulated solution.—T. St.

Ores ; Concentration of ——. Minerals Separation, Ltd., and H. H. Greenway, London. Partly from H. Lavers, Broken Hill, N.S.W., and A. H. P. Lowry, Prahran, Victoria, Australia. Eng. Pat. 16,302, July 15, 1913.

Sodium carbonate (1%) is added to the warm sodium bichromate solution mixed with eucalyptus oil (see Fr. Pat. 458,051 of 1913 : this J., 1913, 1018) to separate certain sulphides such as galena and zinc blende by flotation.—W. R. S.

Ores ; Apparatus for recovering valuable constituents from ——. F. H. Prentiss, Assignor to L. B. Prentiss, San Francisco, Cal., and R. C. Lane, Berkeley, Cal. U.S. Pat. 1,104,132, July 21, 1914 ; date of appl., Jan. 17, 1910.

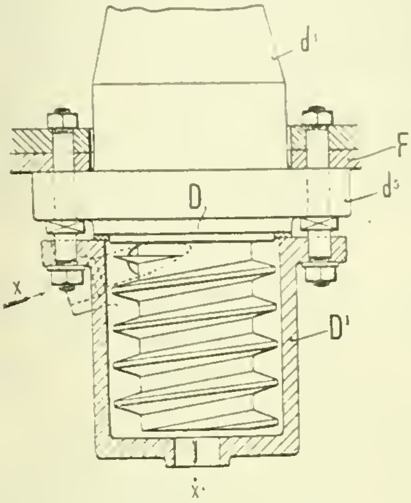
Within and permanently secured to a rotating vessel is a screen having the shape of an inverted cone. A layer of the ore rests upon the screen, forming a jig-bed, and the gangue is washed out by a pulsating stream of water forced into the annular space between the screen and the outer vessel, the valuable particles of high specific gravity being forced through the screen by centrifugal force.—A. S.

Melting furnaces. I. Hall, Birmingham. Eng. Pat. 5664, March 6, 1914.

The bottom of the melting-pot is fitted with a valve which can be worked by means of a lever pivoted outside the cover through which the valve spindle passes in an air-tight manner. The pouring-spout has a gate for checking the flow when charging moulds. A perforated shield surrounds the valve within the melting-pot to prevent dross from flowing out.—W. R. S.

Electrodes for electrical smelting furnaces ; Cooling lower ——. F. Krupp A.-G., Essen, Germany. Eng. Pat. 6731, March 17, 1914. Under Int. Conv., Dec. 13, 1913.

The rod-shaped electrode, D, is provided with a part, d^5, which is joined to the conductor, F, carrying the current, and this part, d^5, lies between the head-piece, d^3, of the electrode and a cooling pot, D^1. The lower end of the electrode, which is provided with helical ribs, is surrounded by the pot, D^1, with a slight amount of clearance, and water is circulated between the ribs, as indicated by the arrows, x, x^1.—B. N.



Electric fusion [of ores] ; Process and apparatus for ——. A. Grabowsky. Fr. Pat. 466,828, March 13, 1913.

The ore is melted in an inclined channel movable longitudinally between two electrodes arranged one behind the other, or the channel may be fixed and the electrodes displaced, or both may be made movable, the relative movement being in harmony with the rate of melting. The charging arrangement, near to the higher electrode, is displaced at the same time as the electrodes, thus automatically feeding the chamber with fresh charges according to the rate of fusion. The channel is formed of several sections, supported on insulated carriages which descend on inclined rails as required.—B. N.

Metal foil ; Manufacture of coloured bronze, and ——. Genthiner Cartonpapierfabrik, Ges. m. b. H., Berlin. Eng. Pat. 9384, April 15, 1914. Under Int. Conv., Dec. 23, 1913.

A layer of colour or bronze is applied to a carrier or backing of fibrous material such as thin paper, which is subsequently destroyed by treatment with hot 10% sulphuric acid and heating, *e.g.* by passing over a heated cylinder or heated plates. Or, the paper may be saturated with the dilute acid, the bronze or colour applied, and the paper then destroyed by heating.—W. R. S.

Metal alloy. S. Wein, New York, Assignor to J. A. Strauss, trustee. U.S. Pat. 1,102,618, July 7, 1914 ; date of appl., Oct. 6, 1913.

An alloy consisting of Al 50 to 85, Te ¼ to 1%, and Zn the remainder.—T. St.

Aluminium alloy. W. A. McAdams, Bay Shore, N.Y. U.S. Pat. 1,104,369, July 21, 1914 ; date of appl., Oct. 16, 1913.

An alloy of tin, silver, cadmium and aluminium.—A. S.

Ores; Apparatus for roasting and sintering ——. A. S. Dwight, New York. Assignor to Dwight and Lloyd Metallurgical Co. U.S. Pat. 1,102,982, July 7, 1914; date of appl., Feb. 2, 1910.

A SHALLOW vessel, divided into two parts by a perforated false bottom, is supported on trunnions, one of which is hollow, and opens into the vessel below the false bottom. Ore containing a combustible is placed on the latter in relatively thin layers and is kept in position by a grid placed on top. Air or other supporter of combustion is passed through the hollow trunnion and the lower compartment and upwards through the ore.—T. ST.

Ore-dust; Process for preparing —— for smelting. W. Cooper, Denver, Colo. U.S. Pat. 1,103,400, July 14, 1914; date of appl., April 20, 1914.

ORE-DUST is saturated with a solution of a calcareous binder, the mass allowed to harden, and then blasted into lumps by means of explosives.—T. ST.

Pyrite; Process of recovering sulphur in elementary form from ——. G. Rigg, Palmerton, Pa., Assignor to New Jersey Zinc Co., New York. U.S. Pat. 1,103,081, July 14, 1914; date of appl., Mar. 27, 1911.

PYRITE is heated at a temperature below its melting point, *e.g.*, at 600°—800° C., in the absence of air, whereby a portion of its sulphur is expelled and magnetic sulphide (pyrrhotite) is formed.—A. S.

Zinc blende; Process of preparing pyritiferous —— for magnetic separation. G. Rigg, Palmerton, Pa., Assignor to New Jersey Zinc Co., New York. U.S. Pat. 1,103,082, July 14, 1914; date of appl., Mar. 27, 1911.

THE ore is heated, in absence of air, at a temperature below the fusing point of pyrite and the dissociation point of zinc blende, in order to convert the pyrite into pyrrhotite (see preceding abstract).—A. S.

Zinc; Muffle furnace for the production of ——. H. Koppers, Essen-Ruhr, and N. Lengersdorf, Bunzlau, Germany. Eng. Pat. 6349, March 12, 1914.

THE furnace is made up of independent units each comprising a group of muffles and separate regenerators. The latter may be placed above or below the muffles but in both cases receptacles with inclined bases are provided to receive any slag escaping from the muffles, and so prevent it from reaching the regenerators. The burning gases in both cases pass over the receptacles so that the slag is kept fluid and can be run off when desired. Ash pockets are provided in front of the muffles, the ash passing down conduits into a discharge channel which is filled with water to cool the ash and prevent the development of dust.—T. ST.

Condenser for zinc vapours. M. Appel, Johnstown, Pa. U.S. Pat. 1,103,123, July 14, 1914; date of appl., Sept. 25, 1913.

THE condenser consists of an outer metallic casing with an inner refractory lining. The zinc enters at the bottom and passes around vertical cooling tubes, arranged in rows, those of each row being spaced apart, and those of adjacent rows being in staggered relation, the corners of the tubes of one row abutting the corners of the tubes in adjacent rows. A gaseous cooling medium is forced downwards through the tubes.—T. ST.

Smelter-fumes; Process of rendering —— useful and recovery of their values. C. S. Vadner, Salt Lake City, Utah. U.S. Pat. 1,103,165, July 14, 1914; date of appl., March 8, 1913.

THE fumes are mechanically purified, then mixed with hydrocarbon gases which have been passed through a column of red-hot coke, and the mixture heated to a high temperature in a gas-converting chamber. The products are cooled to remove moisture and part of the impurities, and then passed through scrubbers of lime rock and ferric oxide into receptacles for use for power and fuel purposes. —T. ST.

[Tungsten] Sintering and stretching process; Combined ——. K. R. R. Seifert, Charlottenburg, Germany. U.S. Pat. 1,103,382, July 14, 1914; date of appl., April 21, 1913.

WOLFRAM (tungsten) or other metals and their alloys are heated electrically in a reducing atmosphere to sintering point, and simultaneously stretched by being passed through a suitable water-cooled die.—T. ST.

Copper matte; Bessemerising ——. J. B. Herreshoff, jun., Assignor to Nichols Copper Co., New York. U.S. Pat. 1,103,925, July 14, 1914; date of appl., Aug. 12, 1912.

COPPER silicate is charged on to the molten mass in a converter and forms a thick viscous mass, without being affected chemically. The charge is then run off, and matte introduced upon the heated silicate, which forms the flux for the new charge.—T. ST.

Gold; Process for saving —— from sand. G. H. Hamilton, Oregon City, Oreg. U.S. Pat. 1,104,112, July 21, 1914; date of appl., Oct. 18, 1912.

THE thoroughly dried sand is passed through a fine-mesh screen and then through a device which is agitated so as to force the finest powdered gold through fine bolting cloth.—A. S.

Ores; Means for and process of treating ——. F. P. Arnold, Carbondale, Pa., and G. F. Wedeman, Washington, D.C. U.S. Pats. 1,104,239 and 1,104,287, July 21, 1914; dates of appl., May 23 and Feb. 12, 1914.

(I.) A RECEPTACLE is mounted on hollow trunnions so that it can be revolved. The trunnions have detachable covers and means are provided for closing their inner ends. The ore is fed into the receptacle from a hopper which can be moved longitudinally into and out of one of the trunnions and means are provided for supplying neutralising agents to the ore. Through the other trunnion passes a pipe for supplying a highly heated gas to the receptacle and fitted with a connection for withdrawing the reaction-gases charged with "values." (2. Live steam is expanded, the condensed water drawn off and the dry steam superheated and passed through charge of comminuted ore impregnated with a neutralisin agent composed of sodium bicarbonate, caustic potash and sodium chloride, the ore being heated and agitated and the effluent gases arrested and condensed.—A. S.

Metallurgical method [for titaniferous iron ore]. A. J Rossi, Niagara Falls, N.Y., Assignor to The Titaniun Alloy Manufacturing Co., New York. U.S. Pat 1,104,317, July 21, 1914; date of appl., April 10, 191

IRON ore containing not less than 3% of titanic oxide i smelted below 1700° C. with carbon and with manganiferous iron ore containing a quantity of manganese oxid amounting to not less than 10% of the titanic oxide.—A.

Electrolyte for use in electro-metallurgical processes. N. H. Dekker. First Addition, dated March 3, 1913, to F Pat. 457,816, July 22, 1912 (this J., 1913, 662).

TWO mols. of an alkali or alkaline-earth sulphate to or of zinc sulphate are employed in the electrolyte, th additional molecule of the alkali or alkaline-earth con pound forming sulphuric acid and oxygen in the anod compartment and alkali or alkaline-earth hydroxide i the cathode compartment. The hydroxide reacts with th metallic sulphate, precipitating zinc hydroxide and r forming the alkali or alkaline-earth sulphate.—B. N.

Copper, lead, and zinc; Separation of —— from sulphi or oxide ores or metallurgical products. W. Borchers a W. Menzel. Ger. Pat. 275,904, July 29, 1913.

SULPHIDE ores containing copper, lead, and zinc a roasted to produce oxides, which are smelted in th electric furnace with the requisite addition of carbonaceous matter; the volatilised zinc and lead are collected in a solution of sulphuric acid, or a mixture of sulphuric and sulphurous acids such as is obtained by passing the gases from the roasting furnace into water. The zinc dissolves whilst the lead is found in the residue. Oxide ores are mixed with sulphide ores and then roasted as described above.—T. F. B.

Steel; Process and apparatus for the manufacture of ——. N. E. Maccallum, Phoenixville, Assignor to F. P. Norris, Phœnixville, and The Phœnix Iron Co., Philadelphia. Reissue No. 13,782, July 28, 1914, of U.S. Pat. 1,057,564, April 1, 1913. Date of appl., May 26, 1914.

See this J., 1913, 492.—T. F. B.

Iron ores; Briquetting ——. W. Mathesius, Charlottenburg, Germany. U.S. Pat. 1,104,124, July 21, 1914. Date of appl., July 22, 1913.

See Fr. Pat. 460,954 of 1913; this J., 1914, 85.—T. F. B.

Rare metals such as thallium and radioactive metals from lead ores; Means for the extraction of —— and production of a white pigment. E. C. R. Marks, London. From Deutsche Felsen Oil Ges. Franzen und Co., Berlin. Eng. Pat. 16,892, July 23, 1913.

See Ger. Pat. 264,526 of 1912; this J., 1913, 1078.—T. F. B.

Chloridizing ores and residues; Process of ——. A. D. Ledoux, New York. Eng. Pat. 17,411, July 29, 1913. Under Int. Conv., Aug. 13, 1912.

See Fr. Pat. 460,579 of 1913; this J., 1914, 88.—T. F B.

Furnaces; Electric ——. W. N. Crafts, Oberlin, Ohio, U.S.A. Eng. Pat. 18,072, Aug. 8, 1913.

ust-proofing products. Ger. Pat 276,122. *See* XIII.

XI.—ELECTRO-CHEMISTRY.

Electrochemical reactions in which the current passes to the electrolyte through a gas space. Haber. Chem.-Zeit., 1914, **38**, 695.

To determine whether the existence of an oxidising or reducing phase, consisting of the charged ions and the material of the electrode, is essential for the oxidation or reduction of depolarisers, a current was passed through dilute sulphuric acid between an ordinary electrode and a cathode arranged in an evacuated gas space. The gases in the cathode space were analysed and found to contain more hydrogen than would be expected from Faraday's law. The oxidation products, persulphuric acid and Caro's acid, were found in the electrolyte The effects of concentration, temperature, duration of experiment, and strength of current were studied.—A. T. L.

Resistivities of glass and fused silica at high temperatures. Campbell. *See* VIII.

Report of National Physical Laboratory. [*Standard cells.*] *See* XXIII.

Patents.

Anodes of massive manganese peroxide; Manufacture of ——. Siemens und Halske A.-G. and M. Huth, Berlin. Eng. Pat. 27,365, Nov. 27, 1913. Addition to Eng. Pat. 605 of Jan. 9, 1909 (this J., 1909, 1145).

The decomposition of the manganese nitrate is carried on in the mould in several phases, and further quantities of manganese nitrate are added continuously during the heating operation.—B. N.

Cells; Galvanic ——. E. Achenbach, Hamburg, Germany. Eng. Pat. 10,616, April 29, 1914.

Magnesia or lime is added to an alkaline electrolyte, and heated to about 100° C. for use in a dry cell.—B. N.

Positive electrodes of alkaline accumulators; Preparation of a mass for the ——. Svenska Ackumulator Aktiebolaget Jungner. Fr. Pat. 467,311, Jan. 14, 1914. Under Int. Conv., Jan. 16, 1913.

The mass is formed of higher oxygen compounds of nickel, which are reduced to a lower state of oxidation, before the formation of the accumulator, by the aid of a reducing liquid or gas. Finely divided zinc or aluminium may be mixed with the active material, so that hydrogen is formed by contact with the alkali of the accumulator or with a neutral liquid; or sugar may be mixed with the mass, so that on immersion in water the sugar is dissolved, thus effecting the desired reduction.—B. N.

Removal of water [by electro-osmosis] from organic and inorganic substances. Ges. für Elektro-Osmose m. b. H., Frankfort-on-Maine, Germany. Eng. Pat. 6993, March 19, 1914. Under Int. Conv., June 2, 1913.

The substance is sub-divided as finely as possible in the presence of an electrolyte before treatment, the operation being carried so far and the quantity of added electrolyte such that the degree of dispersion (fineness of subdivision) of the solid approaches the maximum value as nearly as possible.—B. N.

Organic or inorganic substances; Removal of water [by electro-osmosis] from ——. Ges. für Elektro-Osmose m. b. H., Frankfort-on-Maine, Germany. Eng. Pat. 6995, March 19, 1914. Under Int. Conv., July 21, 1913. Addition to Eng. Pat. 6993 of 1914 (see preceding abstract).

A colloid body, in addition to the electrolyte, is added to the material under treatment.—B. N.

Furnaces; Admission of gas into electric arc ——. Electrodes for electric arc furnaces. Norsk Hydro-Elektrisk Kvælstofaktieselskab. Fr. Pats. 466,961 and 466,962, Jan. 3, 1914. Under Int. Conv., Jan. 17, 1913.

(1) THE air, or other gas, is supplied through the walls of the furnace into the arc, spread into a disc-like form, by means of channels arranged in the forms of frustums of cones, the latter having a common base in the plane of the disc flame. The channels, which communicate in groups with annular distributing chambers, are narrowed towards the interior of the flame chamber, and their position is such that a movement of rotation may be given to the currents of air in a direction opposite to that of the flame; the external annular chambers may serve to feed the flame chamber with cooler gas. (2) Cross-bars, with arrangements for cooling, are adapted to the electrodes to prevent vibration, and both the electrodes and cross-bars are adjustable, the former longitudinally and the latter with respect to the walls of the furnace.—B. N.

Metallic sulphides; Electro-technical application of the electrical properties of ——, particularly for the construction of resistances. G. Mascarini. Fr. Pat. 467,167, Jan. 9, 1914. Under Int. Conv., Jan. 11, and Nov. 5, 1913.

METALLIC sulphides, such as iron sulphide, are used for the construction of resistances employed for the automatic starting of triphase motors with rotary coils, and for short-circuiting the rotor as soon as the speed of the object is attained.—B. N.

Furnace; Electric ——. A. Scott-Hansen, Assignor to Norsk Hydro-Elektrisk Kvaelstofaktieselskab, Christiania. U.S. Pat. 1,096,321, May 12, 1914. Date of appl., Jan. 6, 1914.

SEE Fr. Pat. 466,961 of 1913; preceding.—T. F. B.

Ozone-producer. H. A. Thomson, Assignor to Scientific Treatments, Ltd., Glasgow. U.S. Pat. 1,105,717, Aug. 4, 1914. Date of appl., Aug. 5, 1912.

SEE Eng. Pat. 18,626 of 1911; this J., 1912, 252.—T. F. B.

Electrode masses in alkaline accumulators, composed of oxygen compounds of nickel; Process for regenerating the positive ——. Svenska Ackumulator Aktiebolaget Jungner. Fr. Pat. 466,543, Dec. 24, 1913. Under Int. Conv., Jan. 16, 1913.

SEE Eng. Pat. 72 of 1914; this J., 1914, 796.—T. F. B.

Electrolytic and electrochemical process for de-gumming textile plants. Fr. Pat. 466,555. *See* V.

XII.—FATS; OILS; WAXES.

Fats; Determination of the iodine value of ——. S. Weiser and H. G. Donath. Z. Untersuch. Nahr. Genussm., 1914, **28**, 65—73.

THE iodine values of erucic, elaidic, oleic, ricinoleic and undecylic acids as determined by the methods of Hübl, Waller, Wijs and Winkler were practically concordant. With linolic acid only the iodine value obtained by Winkler's method agreed with theory, the other methods giving too high results. The iodine values of crotonic, tiglic and cinnamic acids could not be determined by the methods of Hübl, Waller and Wijs, whereas nearly theoretical results were given by Winkler's method. (Pharmacop. Hungarica, 1909, XI.). From 0·1 to 0·5 grm. of the fat is dissolved in 10 c.c. of carbon tetrachloride, and 50 c.c. of Winkler's solution (N/10 potassium bromate solution containing 1 to 1·5 grm. of potassium bromide and 10 c.c. of 10% hydrochloric acid) are added. After 30 mins. to 2 hours (according to the iodine value) 10 c.c. of 10% potassium iodide solution are added, and the liberated iodine titrated with thiosulphate solution (see also this J., 1914, 651).—C. A. M.

Shea butter and mowrah fat; Unsaponifiable matter of ——. P. Berg and J. Angerhausen. Z. Untersuch. Nahr. Genussm., 1914, **28**, 73—79.

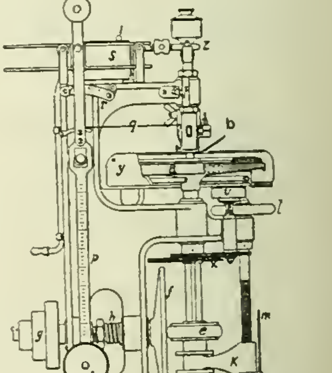
THREE samples of shea butter contained 6·3 to 6·86% unsaponifiable matter, of which 0·95 to 2·55% was insoluble in alcohol. The phytosterol (0·09 to 0·12%) melted at 152°—153° C. Mowrah fat (2 samples) contained 1·7 and 2·2% unsaponifiable matter, with 0·31 and 0·27% insoluble in alcohol, and 0·04 and 0·05% phytosterol (m. pt. 155° C.). After separation of phytosterol the unsaponifiable matter of shea butter had a specific rotation of +38·5 to 39·5 and iodine value 66·6, the corresponding values of mowrah fat unsaponifiable matter being +33·0 to 35·5 and iodine value 68·6. The greater dextro-rotation of this part of the unsaponifiable matter was the only material analytical difference between the two fats. The presence of 10% of the dextro-rotatory portion of the unsaponifiable matter of shea butter had a pronounced effect upon the refraction at 40° C., specific rotation, and saponification value of the fat and fatty acids.—C. A. M.

Oils; Hardening [hydrogenation] of ——. Häpke. Chem.-Zeit., 1914, **38**, 392.

THE largest German factories engaged in hydrogenating oils are the Bremen-Besigheimer Oelfabriken, where only edible fats are hardened to produce "*Brebesol,*" and the Germania Oil Works at Emmerich, which produce only technical products (*talgol* and *candelite*) from whale and fish oils. The hydrogen used in the Bremen Works is obtained from water-gas by the iron-contact process of Messerschmitt at a cost of about 4 pfg. per cb. m. (about 1s. 1¼d. per 1000 cb. ft.). According to the Customs returns the imports of crude oils, etc., int Bremen in 1913 were:—Copra, 37,581; palm and paln kernel oils, 34,271; arachis nuts, 28,624; cotton seed 82,795; and sesame seeds, 28,735; total, 212,006 metri tons, the value of which was estimated at M. 50,000,00 (nearly £2,500,000). Hitherto soya bean oil has not bee imported, although particularly suitable for hardene edible fats.—C. A. M.

Lubricating oils; Machine for testing —— at any ten perature and in connection with surfaces of differe metals. P. M. E. Schmitz. Z. angew. Chem., 191 **27**, 468.

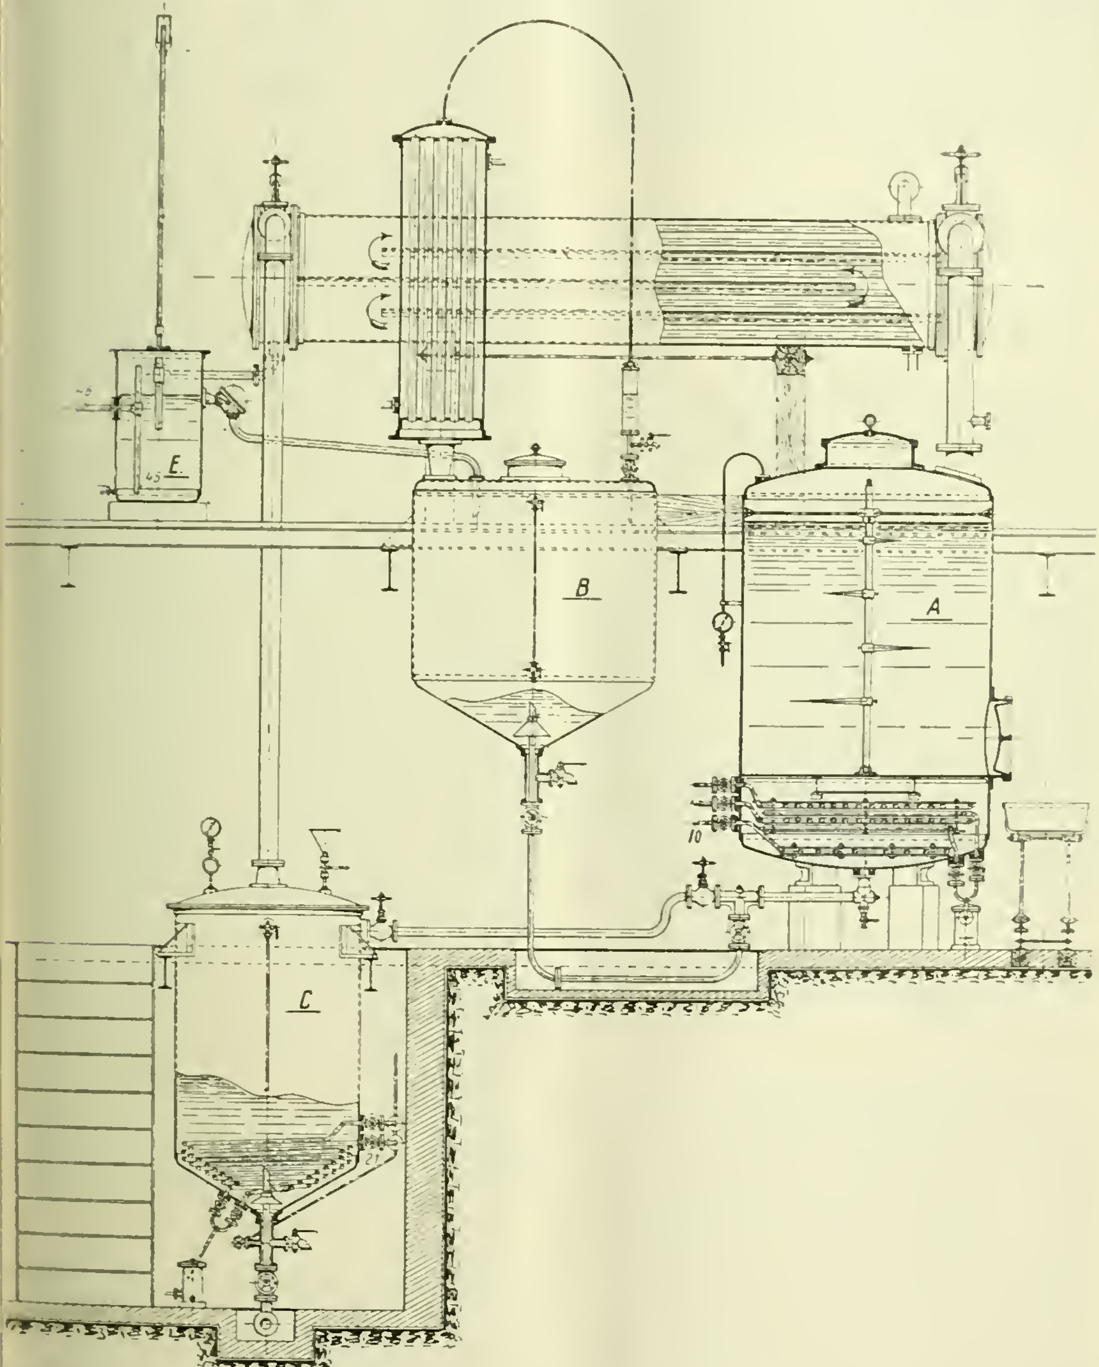
THE friction coefficient, consumption of oil, heat pr duced, etc., may be rapidly determined at 20° to 300° (and at pressures of 0 to 200 kilos. per sq. cm. by th



nachine shown in the diagram. The friction is applied etween the surface of the oil-box, *b*, and the movable lisc, *a* (of any desired metal), which is made to revolve by n electro-motor at a regulated speed, indicated by the osition of the fork, *k*, on the scale, *m*. The temperature f the lubricant is shown by a thermometer introduced nto *b*. The head of the oil-box, *b*, is supported by a ever, connected by the wire, *q*, with the pendulum, *p*. the other end of the lever is a scale pan into which ights are put to measure the pressure per sq. cm., F, the surface of *b* upon the disc, *a*. The friction coicient of the oil is reprsented by $\frac{\phi}{F}$, where ϕ represents the force which moves the pendulum to a point indicated upon the scale, and F the pressure applied to the surface.—C. A. M.

Oils; Apparatus for extracting —— G. Barnick. Chem. Apparatur, 1914, 1, 209—211.

THE material containing oil is extracted in A, by volatile solvent from the tank B. The solution of fat is distilled in C, and the condensed solvent returned from E to the tank B, whilst water is drawn off through 45, 46. Traces of solvent retained by the residue in A are driven off by direct steam admitted through the pipe, 10. An extraction is finished in 8 to 10 hours, and the loss of solvent is stated to be 1 to $1\frac{1}{2}$%.—C. A. M.



Hardened oils in competition with copra oil. E. W. Thompson. Amer. Perfumer, 1914, **9**, 139.

"COMPOUND" lard in the United States is now mainly made from hydrogenated cottonseed oil. The total capacity of plant for hardening oils in Europe for 1914 is estimated at 1,375,000 barrels (of 400 lb.), and the United States output for 1913 at 500,000 barrels. The composition of margarine in Europe (1913) is estimated at :—Copra oil, 169,000 ; palm-kernel oil, 35,000 ; animal fats, 143,500 ; and fluid oils, 150,000 metric tons (2204·6 lb.). Copra oil is being increasingly used for the purpose, and the estimated demand for 1914 is 250,000 tons, or two-thirds of the world's supply. Since 1906 the amount of copra oil produced has trebled. Small quantities of hydrogenated cottonseed oil are now used in the manufacture of margarine in Europe.—C. A. M.

Oil and soap-boiling trades of Marseilles. Diplom. and Consular Report. No. 5377, 1914, 9—13. [Cd. 7048—194.]

RESPECTING the trade of Marseilles in 1913, Consul-Gen. Gurney refers in his Report as follows to the oil, soap-boiling, glycerin, etc., trades, and to the hydrogenation of oils.

The oil and soap-boiling trades.—The oil and soap industries of Marseilles experienced a trying year in 1913, mainly attributable to the extremely high prices of oil and raw materials. Five firms suspended payment, while two others were taken over by a British soap firm. During the last five years, 1909-13, the price of copra oils has risen from the average of 73 fr. 50 c. to 108 fr. 80 c. per 100 kilos. (£1 9s. to £2 3s. per cwt.), while during the same period the price of groundnut (arachis) oil rose from 59 fr. 90 c. to 76 fr. 50 c. per 100 kilos. (£1 4s. to £1 10s. per cwt.). At one time during 1913 copra and arachis oils even fetched 124 and 88 fr. per 100 kilos. (£2 9s. and £1 15s. 6d. per cwt.) respectively. These high prices compelled the soap manufacturers to try and substitute tallow for these oils, and the demand for tallow caused the price of this article to rise from 10 to 47 fr. per 100 kilos. (4s. to 18s. 2d. per cwt.). Many reasons are adduced for the present high prices of the oils in question. The practical substitution of the gold standard for the silver one in India brought about an immediate rise in the price of oil seeds. Arachis seed, which used to sell at Marseilles at 8s. per cwt., rose to 14s. and 16s. per cwt. It might be thought that with the opening up and the exploitation of new countries of production, the price of oleaginous seeds would drop, but with the increased supply came increased demand. Oils were wanted for transformation into "cocose," vegetable butter, table oils, etc. Their use was no longer confined to the manufacture of soap, and accordingly demand outpaced supply. The following are the figures of importation of oils seeds at Marseilles during the last four years. They show a gradual annual decrease :—1910, 665,679 tons ; 1911, 643,634 tons ; 1912, 600,149 tons ; 1913, 589,597 tons.

A noteworthy event of last year was the application to these industries of the hydrogenation process whereby inferior oils are hardened and transformed so as to take the place of fats in the manufacture of soap. The new process has not met with a very enthusiastic reception, though it specially affects three industries, viz., the provision, soap, and stearine industries. Application of the process to the provision trade is hindered by the difficulty of removing all injurious ingredients. In the manufacture of soap hydrogenised oils are good substitutes for tallow, but so long as the price of these substances remains at the level of that of tallow, there appears to be no advantage in substituting the former for the latter. Moreover, at present only small quantities of tallow are employed in the manufacture of soap, otherwise the soap would not be sufficiently soluble. It is in the manufacture of stearine that the hydrogenation of fats and oils is likely to prove of the greatest utility, on account of their richness in stearic acid. There are firms already employing the process in the manufacture of this article with very satisfactory results. All oils are amenable to hydrogenation, but the ones generally used are those of inferior quality, and obtainable at low prices, such as fish oils. Fish oils are greatly sought after, on account of their cheapness, but fish oil imported into France has to pay a duty of 6 fr. per 100 kilos. (2s. 6d. per cwt.). Attempts are being made to get this duty abolished, and a Bill to this effect is already before the French Parliament. This Bill has the support of the soap and stearine manufacturers, but is opposed by the oil manufacturers. Meanwhile the Minister of Finance has stated that if fish oils are granted free entry into the country, it may be necessary to place these oils, when hydrogenised, in a special category, and that it may be found expedient to put a duty on them of 6 fr. per 100 kilos. (2s. 6d. per cwt.) with compulsory declaration of origin. This announcement of the Minister has caused profound dissatisfaction among oil manufacturers. They argue that oils, after having been subjected to the hydrogenation process, are so transformed that it is almost impossible to tell whence they originated, and that hydrogenised fats can be given all the characteristics of tallow. Accordingly it will be practically impossible to differentiate for tariff purposes between hydrogenised fish oils and other hydrogensed oils, and between tallow and hydrogenised fats. After a long discussion the Marseilles Chamber of Commerce has decided to support the proposition of the Minister of Finance with regard to these oils. He proposes to tax them after hydrogenation, if intended for industrial purposes, to the extent of 9 fr. per 100 kilos. (3s. 6d. per cwt.) maximum tariff and 6 fr. per 100 kilos. (2s. 6d. per cwt.) minimum tariff. These are the duties levied on cotton and soya oils intended for soap manufacture.

Oil cakes.—The amount of oil cakes manufactured in Marseilles during 1913 was 281,400 tons as against 285,900 in 1912, a decrease of 4,500 tons. The following figures show that there has been an annual decrease since 1910 :—1910, 317,000 tons ; 1911, 312,100 tons ; 1912, 285,900 tons ; 1913, 281,400 tons.

The neutralising, deodorising and hardening of oils by hydrogenation.—A British soap manufacturing company are building a factory in the Aygalades suburb of Marseille for the hardening of oils by the hydrogen process invented by Sabatier, some 20 years ago, and now being adapted t the industrial treatment of oils. These works will be on the branch line connecting the main railway line with the docks The oils will be pumped up to the works by pipes from th ships' tanks. The company have also bought up th business of two old-established firms of soap boilers, an will carry on business under the names of these two firm A French firm of candle makers has for two years pas manufactured hardened oils by the hydrogenation process for the use of their candle making business. Up to th present this firm has only employed the process in a sm way, but henceforward it will probably go in largely f the hydrogenation of oils. The third concern about t start here, also in the Aygalades suburb, is that of a limite liability company founded in London, with a capital 2,000,000 fr., and registered at Marseilles on February 2 1914 ; 20,000 100-fr. shares have been subscribe by 11 shareholders. As set forth in its statutes, the aim of the company are to acquire all patents, licences, etc to utilise all information and inventions relating to th hydrogenation, the solidification, or any other treatmen of oils, fats, or other similar substances, to buy, sel manufacture, refine, prepare, solidify, or treat in wh manner soever all kinds of oils, fats, soaps, glycerin cattle foods and all oleaginous substances. The rise price of copra oils, due to the enormous demand f edible coconut butter, has led to the hardening of all kin of oils by the hydrogenation process on a large scal notwithstanding the great initial cost of plant. Son 7,000 to 8,000 tons are being turned out weekly in Europ and the output may be doubled in 1914. The oils treate by this process have all the qualities of copra oil, and ca replace that oil in the manufacture of soap. Like cop oil, they can absorb water (10 to 12%) for inferior soap which contain 60% instead of 72% of oil as in the be qualities. The hardness of the hydrogenised oils (the high melting point) can be increased by intensifying th process, the oils becoming as hard as wood. Being al deodorised and neutralised by the hydrogen process, sorts of oils, hitherto considered useless, even rancid ev smelling fish oils, can be treated satisfactorily. A lar rm of candle makers are importing largely Japanese fish oils, which they treat by this process. The hydrogenated oils are now commanding the high prices fetched y copra oils, but as an unlimited supply may soon be placed on the market, a fall in price might be expected, yet he demand for copra oils is so great that it is hoped that prices will be maintained. The supply is not equal to the demand. The Philippines are now using copra very rgely, causing a shortage. Marseilles soap boilers still prefer the copra oil. They fear that with time the smell of these hydrogenated oils may reappear in the soap, and that the colour may vary. Hydrogenated oils somemes become considerably darker in colour on keeping. Copra, costing 120 fr. per ton at the close of 1913, is now at 95 fr. per ton.

Oil seeds. Copra.—Imports of copra in 1913 were 103,136 tons, as compared with 115,117 tons in 1912 and 173,056 tons in 1911. The falling-off is to be attributed to the enormous rise in values already referred to. Under these circumstances the soap manufacturers restricted their purchases and consumption of copra oil to strictest requirements, and replaced this ngredient with tallows, greases and other raw materials which could be supplied at comparatively cheaper cost, but which proved rather prejudicial to the standard quality of Marseilles soap. The crushing of copra was thus considerably reduced, and this industry was not profitable in 1913. Indeed, three of the mills closed or went into quidation. Other large mills making special qualities of refined oils for edible purposes such as "Vegetaline" and "Cocose," have gained profitable results and maintain heir importance.

Groundnuts.—The trade and crushing of groundnuts, decorticated and in shell, continues to increase steadily, and these form the largest and most important branch of he oil-crushing industry in Marseilles. Imports for the year 1913 attained 241,882 tons decorticated kernels and 138,985 tons groundnuts in shell, as compared with 239,195 tons and 120,100 tons respectively in 1912, nearly he whole of these imports being crushed by local mills and the oils sold for edible purposes and for the soap industry. A large portion of imports from the Madras and Coromandel coast, which in previous years all went o the soap kettle, is now being made suitable for edible purposes. This now forms a special and important trade in Marseilles, for French consumption, and also largely for xport to other countries.

Sesame or gingili seed.—Imports for 1913 show an ncrease on the previous year, viz., 26,108 tons as against 8,798 tons in 1912, but are considerably below 1910-11, when the totals were 90,979 and 80,266 tons respectively. The reason given for this diminution is the comparative heaper price of groundnut oils which are more largely aken and appreciated by consumers and margarine manufacturers.

Castor seed.—The imports in 1913 were 25,157 tons, as compared with 16,588 tons in 1912 and 11,509 tons in 1911. This branch of crushing has continued on profitable lines, and two leading crushers have gained high reputation and und a ready sale of their standard qualities, largely to the United Kingdom.

Glycerin.—The glycerin market continued fairly firm throughout the year, a slight downward tendency at the beginning of the year being compensated by a slight upward endency towards the close of the year. The increasing utilisation of oil residues for edible purposes is having, however, rather an adverse effect on the production of glycerin in Marseilles.

Patents.

Fatty acids ; Process of decolorising ——. G. Petroff and G. van Fischenko. Fr. Pat. 467,188, Jan. 10, 1914.

The fatty acids obtained by hydrolysing fats with sulphoacids are decolorised by exposure to a current of air. —C. A. M.

Fats ; Process for hardening and improving the odour of ——. W. Herbricht. Fr. Pat. 467,777, Jan. 27, 1914.

The fat is treated with 20 to 30% of a basic substance, such as milk of lime, or of a solvent, and is then slowly agitated with an acid to liberate oxygen, which will harden and deodorise the fat.—C. A. M.

Sulphonated palmitic products ; Production and utilisation of ——. I. Levinstein, Manchester. Eng. Pat. 16,578, July 19, 1913.

A soluble, miscible or emulsifiable sulpho compound is obtained by treating palmitin or palmitic acid with sulphuric acid, in the presence of a fat, wax, or the like, capable of forming a sulpho acid. The compounds formed will produce soluble, miscible or emulsifiable mixtures with fat, wax or the like. The salts of the sulpho acids may be subsequently formed.—B. N.

Fats and oils ; Process for improving the taste and smell of vegetable and animal ——. W. E. Evans, London. From F. Gössel, Stockheim, Germany. Eng. Pat. 17,510, July 30. 1913.

See Ger. Pat. 273,069 of 1912 : this J., 1914, 652.—T. F. B.

Regenerating decolorising carbon. Eng. Pat. 17,432. *See* IIb.

XIII.—PAINTS ; PIGMENTS ; VARNISHES ; RESINS.

Plastic masses ; Preparation of ——. J. Gsell. Chem.-Zeit., 1914, **38**, 541.

Condensation products are formed in all reactions which yield hydroxybenzyl alcohols or aldehydes, *e.g.* from resorcinol and methylene chloride in the presence of alkali, which produce dihydroxybenzyl alcohols, which on further heating are condensed to solid products. Again by the interaction of phenol and chloroform in the presence of alkali, hydroxybenzaldehyde is obtained as primary product, and this, by the further action of alkali, is decomposed into hydroxybenzyl alcohol and a hydroxycarboxylic acid, which condense as plastic masses when heated. Similar condensation products are obtained by the interaction of phenols and ketones in the presence of hydrochloric acid. For example solid substances are produced by boiling 50 c.c. of acetone and 50 grms. of resorcinol with 3 to 5 c.c. of strong hydrochloric acid. Hitherto this reaction has been regarded as a characteristic of aldehydes only.—C. A. M.

Stick lac ; New alcohol and acid from ——. A. Gascard. Comptes rend., 1914, **159**, 258.

By treating stick lac with boiling 95% alcohol the resin and the greater part of the wax is removed. The insoluble residue consists of woody matter and the bodies of the lac insect, *Tachardia lacca*, gorged with colouring matter. On treating the latter with boiling benzene a waxy substance is removed, which is the ester of the new alcohol. When purified by recrystallisation from benzene it melts at 94° C. It is insoluble in alcohol, ether, and glacial acetic acid, but dissolves in chloroform and benzene. The yield is 0·4% of the original stick lac. When saponified with potash it yields a new alcohol, *laccerol*, $C_{32}H_{66}O$, crystallising from alcohol in lozenge-shaped lamellæ, melting at 88° C. It is sparingly soluble in cold alcohol, ether, chloroform, or benzene; but readily dissolves in those solvents when heated. The acid with which this alcohol is combined in the natural ester is also new. Liberated from its calcium salt it crystallises in lamellæ, melting at 95°—96° C. It has the formula $C_{32}H_{64}O_2$, and has been named *lacceroic acid*, and is closely allied to psyllostearylic acid, $C_{33}H_{66}O_2$, obtained by Sundwick from *Psylla alni*, an insect parasitic on the alder. The ester-wax itself is, therefore, lacceryl lacceroate, $C_{32}H_{63}O_2.C_{32}H_{65}$.

PATENTS.

Red lead; Production of ——. W. Innes, Liverpool. Eng. Pat. 16,700, July 21, 1913.

A CHAMBER, lined with refractory material and with lower inclined side walls and a flat base, is provided with a jacket completely surrounding it, but with a space between the two. A transverse shaft is arranged at each end of the chamber, with sprocket wheels mounted thereon carrying an endless chain, provided with blades or scrapers at intervals. The chain is revolved by suitable means, so that the blades scrape the bottom of the chamber; the blades are made plain for half of their width, and laterally or longitudinally curved for the other half. Lead oxide is supplied to a feed opening at the top of the chamber, and hot air or other gas through a pipe to the space between the jacket and the chamber, for heating the latter. An opening in the bottom of the chamber is controlled by a shutter, so that the product may be delivered into other similar chambers arranged in steps at different elevations, and finally into a suitable receiver.—B. N.

Lakes [from anthracene dyestuffs]: Process for producing ——. Farbenfabr. vorm. F. Bayer und Co. Fr. Pat. 464,948, Nov. 14, 1913. Under Int. Conv., Nov. 21, 1912, Jan. 8, March 20, July 31, and Aug. 4, 1913.

SEE Eng. Pat. 15,557 of 1913; this J., 1914, 492. Similar lakes are obtained from 1-amino-4-hydroxy- and 1-amino-2.4-dihydroxyanthraquinones.—T. F. B.

Paints suitable for wood and textiles; Preservative —— and process of preparing them. Comp. Française d'Injection pour la Conservation des Bois et Tissus. Fr. Pat. 467,113, Jan. 8, 1914.

NEUTRAL or basic pigments (*e.g.* aniline dyestuffs) are dissolved in preservative solvents such as petroleum oil, shale oil, coal-oils, "cresyls" (cresols), etc.—C. A. M.

Rust-proofing products. B. Zschokke. Ger. Pat. 276,122, Dec. 8, 1912.

A SOLUTION of chromic acid or of a salt which has the power to render iron passive, is emulsified with a fat or oil.—T. F. B.

Antifouling paint and varnish. L. Collardon, West Bromwich. U.S. Pat. 1,105.619, Aug. 4, 1914. Date of appl., Jan. 20, 1913.

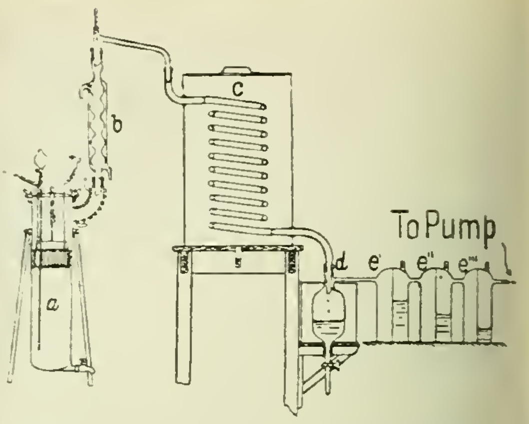
Process for readily dissolving carbohydrates, proteins, horn, bone, etc., by alkali compounds of phenols and alkali acetate. [Manufacture of glue, varnish, etc.] Fr. Pat. 467,045. *See* XV.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Caoutchouc; Synthetic ——. *[Preparation of isoprene from oil of turpentine.]* I. I. Andrejew. Ber. St. Petersburg. Polytechn. Inst. des Kaisers Peter d. Grossen, 1914, 21, 313—368. Chem. Zentr., 1914, 2, 325—326.

AN apparatus (see fig.) for the preparation of isoprene by the pyrogenic decomposition of oil of turpentine comprises a still, *a*, a reflux condenser, *b*, in which warm water (at 50° C.) is circulated, a condenser, *c*, cooled by ice-water, a receiver, *d*, for the crude isoprene, and washing bottles, *e'*, *e''*, *e'''*, containing oil of turpentine. The decomposition of the oil of turpentine is effected by means of a platinum wire of 0·2 mm. diam., electrically heated to incandescence.



Higher yields of isoprene are obtained if carvene and dipentene or aromatic hydrocarbons be added to the oil of turpentine.—A. S.

PATENTS.

Isoprene; Process for preparing ——. I. Ostromisslensky. Ger. Pat. 276,185, March 29, 1913.

CRUDE isoprene containing amylenes is treated with a neutral or basic oxidising agent, or with an alkali or alkaline-earth metal, or an alloy or amalgam of such metal, or with a mixture of an oxidising agent and alkali-metal. Under these conditions amylenes are oxidised or polymerised more rapidly than isoprene, which can be separated from the product of the reaction by distillation. The process can be carried out at the ordinary or at a higher temperature, and a solvent of the isoprene may be used.—T. F. B.

Vulcanising indiarubber solutions containing sulphur; Process of ——. G. Bernstein, Paris. Eng. Pat. 17,195, July 26, 1913. Under Int. Conv., July 26, 1912.

SEE Ger. Pat. 262,708 of 1912; this J., 1913, 919.—T. F. B.

Rubber; Reclaiming ——. H. W. Kugler, Akron, Ohio, U.S.A. Eng. Pat. 28,167, Dec. 6, 1913. Under Int. Conv., Dec. 20, 1912.

SEE Fr. Pat. 466,243 of 1913; this J., 1914, 605.—T. F. B.

XV.—LEATHER; BONE; HORN; GLUE.

Galalith; Manufacture of ——. G. Bonwitt. Z. angew. Chem., 1914, 27, 2.

GALALITH is prepared from a specially pure casein, from sweet milk perfectly freed from fat by centrifuging; the casein is precipitated by rennet, since acids make it quite unsuitable. The curd is drained and dried, forming lumps 8—12 mm. thick. These are ground first in a fluted-roller mill then in a porcelain-roller mill to a gritty meal. The meal is moistened with a given quantity of water and must then be worked up within 12 hours, otherwise it begins to ferment. The moist meal, coloured as required, is worked up between steel helices to a plastic mass which is then hot-pressed in hydraulic presses. The pressed cake is hardened in a solution of formaldehyde of accurately adjusted concentration, which is circulated continuously to avoid the formation of paraformaldehyde The length of treatment varies from 2 to 30 weeks according to the thickness of the articles; the rooms are heated and well ventilated. Drying is effected in a current of warm air. The hardening takes away the extreme brittleness of the casein and imparts the qualities of natura horn. Galalith is a good electrical insulator: a plate 2 mm. thick will resist 16.000 volts. The specific gravity is 1·317—1·35 (celluloid 1·34—1·40) The hardness i

2·5 (celluloid 2). It resists oily liquids and acids but is welled by alkaline liquids. Its chief drawback is its hygroscopic nature; it absorbs 30% of its weight of water in 12 days. It is not elastic like celluloid and breaks when slightly bent. On account of its tendency to flake t cannot be worked so well as celluloid and sheets cannot be prepared less than 2 mm. in thickness. It is chiefly used in the turning trade, and for the manufacture of uttons, combs, and piano-keys; it does not turn yellow. —J. F. B.

Patents.

Tanning agents; Manufacture of soluble ——. J. Y. Johnson, London. From Badische Anilin und Soda Fabrik, Ludwigshafen, Germany. Eng. Pat. 18,259, Aug. 11, 1913.

Natural tanning agents which are partly insoluble can be endered soluble by treatment with substances other han those mentioned in Eng. Pat. 21,982 of 1912 (this J., 913, 919), *e.g.* aromatic sulphonic acids of a non-crystalline haracter which are soluble in water and capable of precipitating gelatin (see Fr. Pat. 462,635; this J., 1914. 66). Example: 10 parts of naphthalene are heated or 6 hours at 150° C. with 10 parts of sulphuric acid. After cooling to 100° C., 2 parts of water and 4·3 parts of 0% formaldehyde are added and stirred. Caustic soda s added till 10 grms. of the product require 10 c.c. of N/1 caustic soda solution for neutralisation. 2000 parts of the paste are introduced slowly with warming into 000 parts of solid quebracho extract in 2000 parts of water. Or, 100 parts of solid quebracho extract may be stirred into 100 parts of a warm concentrated solution of the product obtained by acting on sulphonated cresol with sulphur monochloride (see Addition to Fr. Pat. 13,730; this J., 1914, 209).—D. J. L.

Carbohydrates, proteins, horn, bone, etc.; Process for readily dissolving —— by alkali compounds of phenols and alkali acetates singly or mixed. [*Manufacture of glue, varnish, etc.*] P. J. Contant and J. B. F. Perrot. Fr. Pat. 467,045, Jan. 6, 1914.

The ground material (*e.g.* 100 parts of casein) is left in contact, say for 12—24 hours, with an aqueous solution 00 parts) containing 10% of crystallised sodium phenoxide r acetate. The solution is then filtered and treated with an acid (*e.g.* a 0·2—0·3% solution of sulphuric acid) and with sulphate or other salt of aluminium. The precipitate thus obtained is washed, dried, ground, and dissolved in an alcoholic solution of formic, lactic or acetic acid, or other solvent, and serves for the preparation of glue, varnish, etc.—L. E.

XVI.—SOILS; FERTILISERS.

Soils; Acid. G. Daikuhara. Bull. Imp. Cent. Agric. Exper. Stat., Japan, 1914, 2, 1—40.

The acidity of soils is due not only to the presence of humic acids but also to aluminium and iron compounds; he latter are absorbed by the colloids in the soil, and the absorption compounds act injuriously on vegetation owing to the liberation of acid aluminium and iron compounds when the soil is treated with fertilisers containing mineral salts. More than three-fourths of the soils of Japan and Korea have an acid reaction; those of mesozoic formation are the most acid, then follow the tertiary and palæozoic soils, whilst the alluvial soils are the least acid. To detect acidity in soils, 5 grms. are moistened in a test-tube with a 10% potassium nitrite solution and the tube closed with a plug of cotton-wool from which is suspended a strip of potassium iodide-starch paper. According to the degree of acidity of the soil a more or less deep blue coloration develops on the paper. The acidity may be determined by treating 100 grms. of the soil with 250 c.c. of N/1 potassium chloride solution, shaking the mixture from time to time for 5 days, then drawing off 125 c.c. of the supernatant liquid and titrating it, while boiling, with N/10 alkali solution, using phenolphthalein as indicator. The soil mixture is then treated with a further quantity of 125 c.c. of the potassium chloride solution and the determination repeated, these operations being continued until the soil ceases to yield any soluble acid.—W. P. S.

Manures; Recent advances in the manufacture and use of ——. A. Stutzer. Chem.-Zeit., 1914, **38**, 310—311.

Potassium salts have recently been used for the top dressing of cereals, and are better adapted than kainite for this purpose. Artificial nitrogen compounds from atmospheric nitrogen—nitrolim, calcium nitrate, ammonia, nitric acid, and urea—are being increasingly used in Germany.—O. E. M.

Nitrates; Reduction of —— to nitrites and ammonia by bacteria. M. Klaeser. Ber. deutsch. Botan. Ges., 1914, **32**, 58—61. Chem. Zentr., 1914, **2**, 341.

Of 28 different kinds of bacteria, 27 were capable of reducing nitrate and causing an accumulation of nitrite or ammonia, or both, in the nutrient medium; in presence of peptone, the bacteria withstood the action of large quantities of nitrite. The usual division of nitrate-reducing bacteria into those capable of forming nitrite and ammonia respectively was found to be incorrect; the nature of the reduction product depended upon the composition of the nutrient solution and the reaction (acidity or alkalinity) developed therein. Salts of organic acids produced an alkaline reaction in the medium, favouring the formation of nitrite; dextrose produced an acid reaction, favouring the formation of ammonia. In experiments with *Bac. subtilis*, *tumescens*, and *petasctis*, the quantity of nitrate reduced was approximately proportional to the number of bacteria present during a definite period.—A. S.

X-rays; Influence of —— on vegetation. E. Miège and H. Coupé. Comptes rend., 1914, **159**, 338—340.

The growth of *Raphanus sativus* (radish) and *Lepidium sativum* (garden cress) was promoted by exposure to X-rays, to an extent increasing with the frequency of exposure and the intensity of the radiation, even when the intensity was such as to injure animal tissues. In one case (radish) exposure increased the weight of the leaves by 46%, the bulb by 193%, and the total plant by 59%, as compared with a plant not exposed. The radiation affected slightly the morphology and anatomical structure of the plants, producing in general greater development and better differentiation of the vascular and supporting tissues.—J. H. L.

Hydrocyanic acid and its uses in horticulture. F. P. Sargeant and F. C. Edwards. (Gardeners Chronicle, July 25th, 1914.) Pharmaceutical J., 1914, **93**, 193—194.

In using hydrocyanic acid for fumigation it is necessary to use pure materials to avoid the production of gases (carbon monoxide, sulphur dioxide, etc.) capable of killing the plants. The authors recommend the use of phosphoric acid as being less liable to reduction than sulphuric acid. In carrying out the fumigation it is desirable to avoid the use of excessive quantities of gas, and aim rather at longer exposure to smaller quantities. The plants and atmosphere must be dry and the temperature not above 60° F. (15·5° C.). The fumigation should be performed at dusk when the plants have ceased active assimilation. The amount required under such conditions is about ⅛ oz. sodium cyanide with phosphoric acid per 1000 cu. ft. for green aphis, about ¼ oz. for black or white aphis, thrips and scale, and about 1 oz. to 2 oz. for mealy bug and red spider. The effect of the process on a number of plants was as follows:—

Plants uninjured by phosphoric-cyanide process, 2 oz. to 1000 cubic ft.:—*Anthuriums* (one in flower), *Amaryllis* (young growths), *Anthericum*, *Adiantum cuneatum*, *Abutilon Savitzii*, *Acacia dealbata*, *Asplenium bulbiferum*, *Allamanda*, *Azalea indica*, *Acalypha hispida*, *Bouvardia*, *Calanthe Veitchii*, *Crotons*, *Cattleya labiata*, Chrysanthemums, Cinerarias, *Celosia pyramidalis*, Carnations, *Clivia*, *Cyperus alternifolius*, Cactus, *Centropogon*, *Cypripedium* (in flower), *Dracœna*, *Dendrobium formosum*, *Dieffenbachia*, *Eucharis grandiflora*, *Eucalyptus Globulus*, *Eulalia japonica*, *Epidendron*, Fuchsias, *Francoa ramosa*, *Fittonia*, Gardenias, Gesneria, Gloxinia (in flower), *Habrothamnus*, *Humea elegans*, Ixora, *Impatiens Sultani*, *Lomaria gibba*, *Musa Cavendishii*, Marguerite Mrs. F. Sander, *Nephrolepis*, Orange, *Oncidiums*, *Pancratium fragrans*, Palms, Poinsettias, *Panicum plicatum*, *Pilea muscosa*, *Pandanus Veitchii*, Rondoletia, *Strobilanthes Dyerianus*, *Stephanotis*, Selaginellas, Tradescantias. Plants showing injury by phosphoric-cyanide process, 2 oz. to 1000 cubic ft.:—*Adiantum cuneatum*, young fronds slightly damaged; *Asparagus plumosus* and *Asparagus Sprengeri*, young growths, slightly damaged; Begonia Gloire de Lorraine, slight dropping of flower, foliage uninjured; Browallia; tips scorched slightly; *Coleus thyrsioideus*, defoliated, Cyclamens in flower, some flowers slightly damaged; Heliotrope, badly damaged; Jamaica peppers, slightly scorched; *Mimosa pudica*, leaves dropped after a week; *Mackaya bella*, slightly scorched; Marguerite Mrs. F. Sanders, tips scorched; *Salvia Bethellii*, tips scorched; Tacsonia, slightly injured; *Coelogyne cristata*, foliage injured slightly; Odontoglossum, leaves marked near tip.—W. H. P.

Patents.

Phosphates; Process of rendering soluble insoluble ——. W. S. Landis, Niagara Falls, Ontario, Assignor to American Cyanamid Co., Nashville, Tenn. U.S. Pat. 1,103,059, July 14, 1914; date of appl., July 12, 1913.

A finely-divided mixture of phosphate rock, a soluble sodium salt, water, and carbon is burnt on a perforated grate before the salt has crystallised to an appreciable extent. Air is blown through the mass during the burning operation and the product is finely ground.—A. S.

Fertiliser and process of producing the same. F. S. Washburn, Nashville, Tenn. U.S. Pat. 1,103,115, July 14, 1914; date of appl., March 13, 1914.

An amorphous light-coloured fertiliser consisting essentially of ammonium phosphate mixed with small quantities of aluminium and iron phosphates, and practically devoid of constituents not available as a plant food, is prepared by treating phosphate rock with sulphuric acid, and adding the resulting crude solution of phosphoric acid to a solution containing excess of ammonia, *e.g.* to a solution of mono-ammonium phosphate containing di-ammonium phosphate. —A. S.

Fertilising compound. T. L. Willson and M. M. Haff, Ottawa, Assignors to Southern Investment Co. of Canada, Ltd., Montreal, Canada. U.S. Pat. 1,103,910, July 14, 1914; date of appl., Dec. 18, 1911.

A powder formed "from a fused mass containing an alkali and a phosphate enriched with vapours of potash, phosphoric acid, and ammonia."—A. S.

Manure-stuff; Non-hygroscopic —— and process of making same. H. Stoltzenberg, Breslau, Assignor to Melasse-Schlempe G. m. b. H., Berlin. U.S. Pat. 1,104,326, July 21, 1914. Date of appl., July 7, 1913.

See Fr. Pat. 459,872 of 1913; this J., 1913, 1165.—T. F. B.

Peat; Treatment of —— for manurial and other purposes. W. B. Bottomley, London. U.S. Pat. 1,106,275, Aug. 4, 1914. Date of appl., July 15, 1913.

XVII.—SUGARS; STARCHES; GUMS.

Drying beet slices; Heat lost in ——. F. R. Janak. Deut. Zuckerind., 1914, 39, 641.

If 325,000 kilos. of wet pressed beet slices containing 14% of dry substance be desiccated to a product containing 90% of dry substance, the heat required is as follows: used in the actual operation of drying, 176,000,000 cals.; lost with the evaporated water passing into the flue, 24,840,000; lost with the fuel flue gases, 54,000,000; lost with the hot slices on their removal, 4,500,000; lost in the furnace ashes, 3,000,000; total 262,340,000 cals. Efforts should be made to utilise the heat escaping into the flue with the evaporated water and the furnace gases either in the slice desiccation apparatus or in a juice or syrup-heater, whilst the evaporated water passing into the flue might be condensed to give an oil-free water suitable for feeding to the boilers.—J. P. O.

Sucrose; Comparative study of different methods of determining —— by double polarisation. R. Gillet. Bull. Assoc. Chim. Sucr., 1914, 31, 992—1033.

Alkaline direct polarisation. The Clerget and Herzfeld methods, involving alkaline direct polarisation and acid inversion polarisation, cannot give accurate results on account of the interference of the optically active amino-acids. *Acid direct polarisation.* The use of hydrochloric acid and urea, as recommended by Andrlik (this J., 1911, 63) gives accurate results in the case of beet molasses, but is not practical, by reason of the rapidity with which it is necessary to work in order that the sucrose may not be affected by inversion due to the acid. With sulphurous acid, however, following the directions of Pellet and Ogilvie (this J., 1912, 1195) exactly the same result is obtained as in the Andrlik modification, while manipulation is easy. *Neutral double polarisation.* Theoretically, the modification elaborated by Saillard (this J., 1913, 836) is faultless, but practically it is difficult to operate, and cannot be recommended for routine factory work. *Hydrolysis with invertase.* Following the procedure devised by Ogilvie (this J., 1911, 62) results agreeing closely with those found by the Pellet and Andrlik modifications were found. As the result of a number of determinations with beet molasses it is concluded that the most accurate and also the most practical method is that of Pellet using sulphurous acid in excess for making the direct polarisation. —J. P. O.

Action of some amylases on dextrins. Gruzewska. *See* XVIII.

Wood; Steaming of ——. Heuser. *See* V.

Patents.

[*Sugar.*] *Diffusion process and apparatus.* L. Naudet Fr. Pat. 466,590, March 6, 1913.

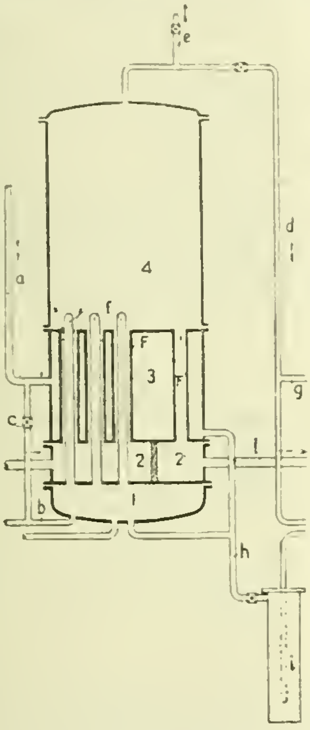
In a diffusion apparatus with forced circulation (see Fr Pat. 329,139 of 1903; this J., 1903, 1008) the juice fron a cell is forced into a vessel from which it can be made t flow, without passing through the heater, to the pip conveying the hot juice used for displacement, which i thus delivered in constant volume and at a relatively hig temperature.—O. E. M.

Syrups; Product for the refining of ——, which effects thei simultaneous decolorisation, defecation, and clarificatio P. Lagrange. First Addition, dated March 4, 1913, t Fr. Pat. 459,213, Aug. 29, 1912 (this J., 1913, 1166).

To regenerate the spent product, it is suspended in wat and treated with a solution of 15—20 parts of sodiu hypochlorite per 100 parts of dry product, and with hydr chloric acid, the latter being added in small portions with stirring. The whole is then made alkaline with milk of lime; the hydrated calcium phosphate and alumina thus precipitated, form with the charcoal still in suspension, a homogeneous product which is pressed and washed for use in refining a further quantity of syrup.—L. E.

Sugar juices; Apparatus for the rapid evaporation of —— under low pressure and with small differences of pressure between the effects, permitting complete utilisation of the waste steam without a condenser. E. Portemont. Fr. Pat. 467,629, Jan. 19, 1914.

THE apparatus comprises any number of effects of which the first is shown. Each effect is divided into compartments, 1, 2, 2′, 3 and 4, of which 1 and 4 are connected by the narrow tubes, *f*. Waste steam is admitted by the pipe, *a*, to compartment, 3, and fresh steam by the pipe, *b*, to compartment, 1; if desired, *a* and *b* may be connected by the branch pipe and cock, *c*. The water condensed in compartments, 1 and 3, passes to the siphon, , and thence to compartment, 1, of the next effect. The uice to be treated s admitted by the pipe, *k*, to compartment, 2, ascends hrough the concenric spaces of the ube system, F, flows over the upper tube plate, descends hrough the tube ystem, F′, to compartment, 2′, and asses by the pipe, *l*, o the next effect. eing sent from the ast effect to a concentrating apparatus. The vapour from the juice passes y the pipe, *d*, and branch, *g*, to compartments, 1 and 2, the next effect, whilst part of this vapour may be ithdrawn by the branch, *e*, and utilised elsewhere; the apour similarly withdrawn from the final effect is almost t atmospheric pressure.—L. E.



ugar masses; Colouring agent for viscous —— especially for masses destined for making caramels. Ungemach A.G., Els. Conserven-Fabrik & Import-Ges. Fr. Pat. 466,925, Dec. 31, 1913. Under Int.Conv., Feb. 25, 1913.

nown quantities of the colouring matter and sugar or latin are dissolved in water and concentrated at as low temperature as possible, the product being formed into blets; or the colouring matter is mixed with a quantity the mass used for making caramels, the whole being rmed into tablets. These tablets serve to colour sugar asses uniformly and to any desired degree.—L. E.

red products [adhesive]; Manufacture of ——. Norsk Tangsyndikat, Christiania. Eng. Pat. 5146, Feb. 27, 1914. Under Int. Conv., March 1, 1913.

Regenerating decolorising carbon. Eng. Pat. 17,432. *See* IIa.

XVIII.—FERMENTATION INDUSTRIES.

Hops; Nitrogenous constituents of ——. A. C. Chapman. Chem. Soc. Trans., 1914, **105**, 1895—1907. (See this J., 1913, 837).

A NUMBER of samples of hops were found to contain 1·72—4% of nitrogen of which 0·44—0·9% was in a form soluble in hot water. The average composition of the soluble portion (referred to dry hops) was as follows:—Soluble proteins and albumoses, 0·046; ammonium salts and amides, 0·100; amino-substances 0·095; bases and unclassified nitrogen precipitated by phosphotungstic acid, 0·218; unclassified nitrogen not precipitated by phosphotungstic acid, and taken by difference, 0·037%. Besides the compounds previously mentioned (*loc. cit.*), the following have been isolated:—Aspartic acid, potassium nitrate, and one which was probably arginine. A trace of an oily substance with an odour very like that of coniine was also obtained. Cultivated hops contain no morphine or, at most, traces which can have no physiological significance.—L. E.

Brewing water containing manganese. O. Fürnrohr. Z. ges. Brauw., 1914, **37**, 369—372, 381—384.

THE presence of manganese in brewing water is undesirable since it increases the protein-content of the wort and thus also tends to mask the hop flavour of the beer. The water may be freed from iron and part of the manganese by filtration and aeration in a coke tower and then from the remainder of the manganese by addition of lime water. This process is unsatisfactory, however, since the carbon dioxide-content of the water is liable to vary from day to day, and with addition of a constant proportion of lime water the alkalinity of the treated water would vary also. The best method for removing manganese from brewing water is to treat the latter with a certain proportion of lime water, filter from precipitated lime, magnesia, iron and manganese, and remove the remaining manganese by filtration through a special sand filter prepared with manganese dioxide.—L. E.

Yeasts and mould fungi; Recent investigations of the protein metabolism of ——. F. Ehrlich. Z. angew. Chem., 1914, **27**, 48—52.

A GENERAL account of the results of researches on the action of yeasts and moulds on amino-acids (see this J., 1905, 683; 1907, 28, 480; 1909, 848; 1910, 835; 1911, 231, 566; 1912, 505, 506; 1913, 986; 1914, 273). The acids and alcohols formed from amino-acids as by-products of fermentation (*loc.cit.*) give rise to esters which sometimes largely determine the flavour and aroma of alcoholic beverages. The transformation of tyrosin into tyrosol by yeast in presence of sugar is practically quantitative, but about 15—20% of the tyrosol is converted into esters, chiefly of acetic and succinic acids. Slow fermentation favours the formation of esters but the most important factor is the type of yeast employed. Many nitrogenous substances which are toxic towards animals are readily attacked by mycoderma-yeasts and moulds, and converted into innocuous substances: *e.g.*, aniline is precipitated from solutions as a flocculent oxidation-product, and alkaloids such as nicotine and quinine lose their nitrogen and are in part, assimilated.—J. H. L.

Alcoholic fermentation. P. Nottin. Bull. Assoc. Chim. Sucr., 1914, **31**, 956—959. (See this J., 1914, 37.)

In fermentation, the yeast crop increases at first, and then decreases slowly before fermentation is complete. For a given amount of sugar consumed, the yeast crop is greater the lower the concentration of sugar initially present. The proportion of yeast crop to sugar fermented and the rate at which the carbon dioxide escapes from the fermentation liquid are greatly affected by the nature of the glass of which the fermentation vessel is made.—L. E.

Dextrins ; Action of some amylases on——. Z. Gruzewska. Comptes rend., 1914, **159**, 343—345.

It has already been proved that pancreatic amylase acts less energetically on glycogen than on starch. Similar differences were observed with achroo dextrin and erythro-dextrin prepared respectively from glycogen and starch by the action of hydrogen peroxide at 37° C., though these dextrins were less rapidly hydrolysed than their parent carbohydrates. Further experiments with vegetable amylase, Taka diastase and juice from snails confirmed the author's conclusion that glycogen and dextrins prepared therefrom differ in constitution from starch and its dextrins.—J. H. L.

Saccharomycetes (yeasts) ; Behaviour of some —— to inulin. V. Grafe and V. Vouk. Z. Gärungsphysiol., 1913, **3**, 327—333. Chem. Zentr., 1914, **2**, 339.

Many kinds of *Saccharomyces* fermented pure solutions of inulin ; the organisms did not develop well. Yeasts incapable of fermenting inulin were able to assimilate it. Most of the yeasts tried were able to ferment inulin in chicory extracts, *i.e.*, in presence of lævulose ; *Schwanniomyces occident.* was specially effective. In many cases the quantity of carbon dioxide produced by fermentation was very small, and substances of the most varied odours were formed in addition to alcohol.—A. S.

a-Glucosidase ; Specific nature of——. A. Aubry. J. Pharm. Chim., 1914, **10**, 23—26.

An aqueous extract of a culture of *Aspergillus niger*, exhibiting strong hydrolytic activity towards maltose, was without action on α-methylglucoside. It is concluded that maltase and α-glucosidase though both present in air-dried bottom fermentation beer yeast are two distinct enzymes (see Bourquelot and others, this J., 1913, 251).
—J. H. L.

Wines ; Volumetric determination of sulphurous acid in ——. L. Ferré. Bull. Assoc. Chim. Sucr., 1914, **31**, 959—963.

Total sulphurous acid.—A slow current of carbon dioxide is passed through 100 c.c. of the wine acidified with 2 c.c. of syrupy phosphoric acid, and then through a reflux condenser (to retain all volatile products except carbon dioxide and sulphur dioxide) to two absorption vessels in series. The first of these vessels contains 40 c.c. of a solution of 3·968 grms. of iodine per litre, and the second contains 5 c.c. of an equivalent solution of sodium thiosulphate. When all the air has been expelled from the apparatus, the wine is heated and kept gently boiling for half an hour, the current of carbon dioxide being continued. The solutions in the two absorption vessels are then united and titrated with thiosulphate of the same strength as that previously used. If n c.c. of thiosulphate are required, the sulphur dioxide-content of the wine $= 10[40-(n+5)]$ mgrms. per litre. *Combined sulphurous acid.*—100 c.c. of the wine are treated with n c.c. (see above) of the iodine solution and then with n c.c. of an equivalent solution of sodium arsenite. Then if the whole of the sulphurous acid is in the free state, the iodine added just suffices to oxidise it, and if none of the sulphurous acid is free, the arsenite just suffices to reduce the iodine. The wine is then further treated as in the previous case.
—L. E.

Alcohol from wood waste ; Manufacture of ethyl——. Preliminary experiments on the hydrolysis of white spruce. F. W. Kressmann. J. Ind. Eng. Chem., 1914, **6**, 625—630.

The experiments were made in a rotary digester consisting of a thin cast-iron inner shell (5 ft. long by 2½ ft. diam.), lined with acid-proof enamel, and an outer shell of steel. Steam was introduced simultaneously into the inner shell and the jacket, and the digester was connected with an enamel-lined cast-iron tank so that sulphuric acid could be introduced from the latter whilst the digester was under pressure. The vapours blown off at the end of a digestion were condensed in a quartz coil. The digester was charged with sawdust equivalent to about 100 lb. of dry substance and with 2 lb. of 90—95% sulphuric acid diluted so that at the end of the digestion the amount of water was at least four times the dry weight of sawdust. The results are given in curve-diagrams and tables. The maximum yield of sugar was obtained at a pressure of 7·5 atmospheres. Increasing the time of digestion did not increase the yield but so affected the mechanical condition of the residue as greatly to increase the difficulty and cost of handling it ; with sawdust it was most advantageous to blow off as rapidly as possible from a pressure of 7·5 atmospheres as soon as that pressure was attained. From 22 to 23% of the dry weight of white spruce sawdust was converted into sugar and about 70% of the sugar was fermentable, giving a yield of alcohol equal to more than 91% of the theoretical quantity. The yield of acetic acid was about 1·4% and that of formic acid varied from 0·1 to 0·6% according to the experimental conditions.—A. S.

Denatured alcohol in the United States. Oil, Paint, and Drug. Rep., July 27, 1914. [T.R.]

The Committee on Ways and Means of the United States House of Representatives has reported favourably on a Bill introduced by Representative Palmer, the object of which is, briefly, to permit the manufacture of denatured alcohol by mixing domestic and wood alcohol while in process of distillation. The Bill has been drafted to permit the utilisation of a new process in respect to which application had been made to the Commissioner of Internal Revenue, it having been discovered that existing legislation did not cover such a process. The process in question consists in passing the vapours obtained in the distillation of wood, or similar vapours containing denaturing substances, into the usual apparatus of an ethyl alcohol distillery, so that the ethyl alcohol is mixed with the denaturant before distillation. The product is called "distol," and is claimed to be very cheap and suitable for industrial purposes in that it differs in no essential respects from what is generally known as denatured alcohol.

Distillation ; Theory of fractional —— of mixtures of water and alcohol. E. Chenard. Bull. Soc. Chim., 1914, **15**, 646—649.

A theoretical study of fractional condensation. The frequent removal of liquid during the condensation of aqueous-alcoholic vapours permits of the most effective separation of the constituents, and for this reason the best condensers are those with a large number of successive compartments each retaining only a small quantity of liquid. (Cp. Hirsch, this J., 1910, 1266.)—J. H. L.

Spirits ; Procedure to be observed in connection with the use in manufactures of —— on which duty has not been paid (Sec. 8 of the Finance Act, 1902). Memorandum prepared by the Board of Customs and Excise

1. Any person desiring to use spirits without payment of duty in any manufacture carried on by him must make application in writing to the Commissioners of Customs and Excise for authority to receive and use such spirits, and must prove to the satisfaction of the Commissioners that the use of methylated spirits would be unsuitable or detrimental.

2. The applicant must give full particulars of the situation of the premises upon which and the purpose for which

he spirits are to be used, together with a description of the rocess of manufacture. He must also state the means y which it is proposed to make the spirits unpotable before nd during use, and the quantity likely to be required in the ourse of a year.

3. Any person authorised to receive spirits on which uty has not been paid must, if so required by the Comissioners of Customs and Excise, provide upon his preises a warehouse, structurally secure to their satisfaction, nd all such spirits received must be deposited and retained herein until delivered on proper notice to, and in the resence of, the Officer. He must also, if so required, rovide a room approved by the Commissioners in which ust be fixed a vat or other vessel of sufficient size to dmit of at least one hundred bulk gallons of spirits being ndered unpotable at one time, and must also provide tisfactory accommodation for the Officer of Customs nd Excise in attendance at his premises. No charge is sually made for the services of this Officer.

4. Security to the satisfaction of the Commissioners of ustoms and Excise must be given for the due removal, fe custody, and proper use of the spirits, and the due servance of all regulations and conditions made by the ommissioners.

5. The substance or material to be used for the purpose rendering spirits unpotable, and the mode in which the irits are to be rendered unpotable must be approved by e Commissioners of Customs and Excise, and the person thorised to receive spirits upon which duty has not been id must, if so required by the Commissioners, provide a ore to be approved by them, and used solely for storing d keeping the substance or material so approved.

6. Spirits which have been rendered unpotable under ese regulations shall not thereafter be purified in any anner or be recovered by distillation or any other means, cept with the express sanction of the Commissioners of stoms and Excise.

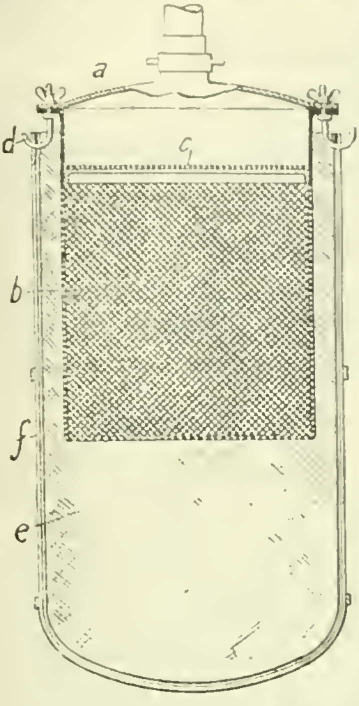
PATENTS.

negar; Process for the manufacture of —— by the application on a commercial scale of a new mycoderm. H. Boulard, Paris. Eng. Pat. 25,289, Nov. 5, 1913. Under Int. Conv., June 27, 1913.

PURE culture of *Mycoderma aceti Asiaticus Boulard* . 2, a mycoderma occurring abundantly in the Far East, grown in a flask containing an alcoholic liquid of high tract-content, *e.g.*, fermented malt wort, containing a grms. of reducing sugars per litre, and the vinegar thus tained is run, at 35° C., for 48 hours, in thin layers over faces consisting of half-round sticks of green bamboo, ich are soon covered with a thin layer of the mycoderma. etification may also be effected in casks, in which case litres of the liquid may be added to 100 litres of the egar, still containing the mycoderma, in a 225—250- e cask. The cask, which is placed on its side, should e a round opening of about 8 cm. diam. in the upper rt of one end and another opening in the side. The led wort is thus acetified in 12—14 days. Acetification not arrested by immersion of the mother of vinegar nor shaking the cask, as occurs with other processes.—L. E.

wing: Filter particularly adapted for use in ——. J. Bearman, London. Eng. Pat. 22,698, Oct. 8, 1913.

E filter (see fig.) is intended particularly for filtering the rt as it passes from the hop-back to the cooler. It nprises an inner vessel divided into two compartments a perforated partition, c; the lower compartment, *b*, perforated walls and contains spent hops or other ring material. Around the inner vessel and spaced apart therefrom is a filter-bag, *e*, supported in an open metal frame, *f*, suspended on hooks and secured to the cover, *a*. The filter is connected with the delivery pipe of the hop-back by means of the junction passage in the cover, *a*.—A. S.



Brewing apparatus. C. B. Davis, New York. U.S. Pat. 1,102,647, July 7, 1914; date of appl., Aug. 12, 1912.

THE apparatus comprises a sieve and a controlling member, and means for bringing them together to close the perforations of the sieve, or for spacing them apart.—L. E.

Still. B. S. Lindsay, Baltimore, Md. U.S. Pat. 1,100,834, June 23, 1914; date of appl., Sept. 25, 1908.

THE beer (wash) is passed through a heater and vaporiser and the spent "slop" from the latter passes to a dryer (evaporator). The steam given off in the evaporator is used to heat the vaporiser and the heater.—W. H. C.

Distilling apparatus. C. T. Hanna, Philadelphia, Pa. U.S. Pat. 1,102,910, July 7, 1914; date of appl., April 12, 1912.

THE spirit vapour passes upwards through a cylindrical conduit divided by partitions into chambers and containing inner perforated cylinders open below and closed above, a cup which is formed on the top of one cell forming a seal for the open bottom of the cell above. The perforated cylinders are provided with flanges which act as baffles compelling the vapours to pass inwards and outwards through the perforations. The heavier portions condense and are drawn off through drain pipes, whilst the lighter vapours pass on to a horizontal water-cooled separator of a similar type and the spirit vapours pass from this to a final condenser.—W. H. C.

Yeast; Manufacture of ——. T. Ruf. First Addition, dated Dec. 10, 1913, to Fr. Pat. 440,841, March 2, 1912 (this J., 1912, 834).

A MIXTURE of 125 parts of raw sugar and 150 of meal (consisting of equal parts of rye and potato meal) is treated with boiling water to dissolve the sugar and gelatinise the starch. The product is mixed at 30° C. with 1000 parts of yeast of any origin, which has been treated with a small quantity of amyl acetate or "pineapple ether."—L. E.

Marcs, wine lees, tartars, gritty matter, still crystals, etc., and any tartrate materials ; Processes and apparatus for treating ——, and the recovery, at the ordinary temperature, of the whole of the tartrates as cream of tartar of high purity. G. Arrivant and R. Teyssier. Fr. Pat. 467,413, March 28, 1913.

The material, contained in a number of vessels arranged like a diffusion battery, is treated with hydrochloric acid and then with water. The solution of tartaric acid and potassium chloride thus obtained is decolorised, *e.g.*, with ozone, and filtered ; it is then treated with calcium tartrate whereby potassium bitartrate of 98—99% purity is precipitated. The tartaric acid remaining in solution may be recovered as calcium tartrate by addition of calcium carbonate.—L. E.

Malt extracts ; Process of removing the bitter taste from ——. R. Weyermann, Bamberg, Germany. U.S. Pat. 1,105,119, July 28, 1914. Date of appl., March 4, 1914.

See Eng. Pat. 5025 of 1914 ; this J., 1914, 659.—T. F. B.

XIXA.—FOODS.

Foods for infants ; Analysis and composition of some proprietary ——. J. L. Baker. Reports to the Local Gov. Board, 1914, Food Report No. 20, 1—83.

One hundred and six samples of different brands of proprietary infants' foods were obtained from various parts of the country and submitted to examination ; certain of these samples were analysed fully. The suitability of foods containing starch is discussed and a synopsis is given of the recorded evidence regarding the effect of such foods on infants. Misleading statements in the labels or advertisements of the foods are noted, and suggested methods for exercising control over the foods are given together with the regulations obtaining in other countries. Results of the analyses of 29 of the foods are given in detail. Four of the samples contained dried milk and all contained sucrose ; usually the quantity of the latter was small, but in at least 8 cases the sugar must have been added, as the amount varied from 9·2 to 16%. The fat-content was small in almost all the foods, not exceeding that naturally present in the flour used ; the highest quantity of fat found was 16%. All the samples, except two, contained appreciable quantities of unaltered starch ; the majority contained over 60%, the highest amount found being 75%. Most of the foods were prepared from wheat flour, but oat, banana, and lentil starches were present in some of the samples. The proteins varied from 1·8 to 24·2%, and the mineral matters from 0·5 to 3·8%. Many of the foods contained saccharifying diastase whilst liquefying diastase was present in about one-half of the samples.—W. P. S.

Milk ; Capillary analysis of ——. F. Goppelsroeder. Sealed note 706, dated Oct. 26, 1892. Bull. Soc. Ind. Mulhouse, 1914, **84**, 281—284.

A proposal to use capillary analysis by means of strips of filter-paper or the like in the examination of milk. A bibliography of the authors' subsequent publications on the subject is given.—J. B.

Proteins of wheat and rye ; Physico-chemical properties of the ——. J. Gróh and G. Freidl. Biochem. Zeits., 1914, **66**, 154—164.

Examination by physico-chemical methods of proteins separated by fractionation from wheat and rye showed that gliadin is the only alcohol-soluble protein present in wheat gluten ; good and bad glutens yield the same substance. The protein extracted from rye flour consists of a mixture of substances which are exceedingly difficult to isolate ; rye flour does not contain a protein identical with the gliadin of wheat gluten.—W. P. S.

Tea ; Investigations of the manufacture of ——. S. Sawamura. Bull. Imp. Cent. Agric. Exper. Stat., Japan, 1914, **2**, 75—83.

Oxydases are much more sensitive to high temperatures than are other enzymes, such as diastase, and the usual operation of steaming tea leaves must be so regulated as to kill only the oxidising enzymes ; this may be effected by limiting the duration of the steaming to about 30 seconds. It is probable that the remaining enzymes play an important part in the first stage of rolling tea leaves and that the production of a fine aroma is due to their action. The chief effect of rolling tea leaves is the increase in the quantity of readily soluble constituents ; the rolling operation crushes the cells and the liberated juices dry on the surface of the leaves. Green tea is improved in quality by being fired at 70° C. for 1 hour ; black tea may be fired at 80° C. When the tea is not strongly heated, the amount of soluble constituents increases but slightly ; high temperatures cause a diminution in the quantity of total soluble matters.—W. P. S.

Preservatives ; Chemical ——. Cinnamic acid. H. Serger. Chem.-Zeit., 1914, **38**, 354—356.

The preservative action of cinnamic acid in foods, beverages, etc. is superior to that of benzoic acid. Better results are obtained with the free acid than with the sodium salt. Doses of 0·1 grm. taken three times daily for a period of 10 days had no ill effect on the human subject. (See this J., 1910, 367.)—F. Shdn.

Government Laboratory. Report of Principal Chemist for year ended March 31, 1914. See XXIII.

Hardened oils in competition with copra oil. Thompson. *See* XII.

Colour reaction of citric acid. Häussler. *See* XXIII.

Patents.

Grain ; Treatment of ——. E. Samuelson, Banbury, and J. Backhouse, Bootle. Eng. Pat. 17,214, July 28, 1913.

The whole grains are sprayed with a solution of an "improver" (*e.g.* a phosphate), then heated to not above 130° F. (54° C.), and ground.—W. P. S.

Cocoa, coffee, and tea residues ; Process of denaturing and defecating —— applicable to the extraction of the active principles. L. M. Rousseau. Fr. Pat. 466,888, Dec. 31, 1913.

The residues or waste products are treated with a solution of a ferrous salt ; subsequent addition of an alkali or alkaline-earth precipitates the iron together with tannin and colouring matters and the extraction of the active principles is facilitated.—W. P. S.

Malt flour for baking purposes ; Process of preparing ——. Hatt Freres. Fr. Pat. 467,158, Jan. 9, 1914. Under Int. Conv., Feb. 17, 1913.

Barley rich in proteins is allowed to germinate for 2 to 3 weeks at 10° to 15° C., then dried rapidly under reduced pressure at 45° to 50° C., and ground.—W. P. S.

Liquids containing fatty globules [milk and cream] ; Process and apparatus for the sterilisation of ——. N. J. Nielsen. Fr. Pat. 467,373, Jan. 16, 1914. Under Int. Conv., Jan. 16, 1913.

The milk or cream is passed successively through a series of heating and cooling tubes and, in order that the fatty globules may not be broken up by irregularities in the heating and cooling processes, the main pump supplying the liquid to the apparatus is supplemented by pumps o the heating and cooling tubes. The rate of flow of the liquid is controlled by regulating valves.—W. P. S.

Milk ; Process and apparatus for clarifying [removing di from] ——. Aktiebolaget Separator. Fr. Pat. 467,807 Jan. 28, 1914. Under Int. Conv., July 21, 1913.

A centrifugal apparatus is used, the milk being intro duced through a central opening, passing to a chambe at the circumference of the drum where the dirt is de posited, and then directed towards the centre and to th outlet.—W. P. S.

ood ; *Process for preserving —— or freeing it from germs.* Ges. f. Sterilisation G. m. b. H., and M. Riegel, Berlin. Eng. Pat. 17,400, July 29, 1913.

ee Fr. Pat. 460,912 of 1913 ; this J., 1914, 98.—T. F. B.

argarine and the like ; Method of manufacturing ——. E. V. Schou, Copenhagen. Eng. Pat. 17,616, July 31, 1913. Addition to Eng. Pat. 4278, Feb. 19, 1913.

ee Addition of July 30, 1913, to Fr. Pat. 454,640 of 1913 ; is J., 1914, 215. The emulsion is first cooled to about 7° C.—T. F. B.

alt-extract preparations ; Non-hygroscopic —— and process for making the same. F. Elger, Basle, Switzerland, Assignor to Hoffman-La Roche Chemical Works, New York. U.S. Pat. 1,100,176, June 16, 1914. Date of appl., Feb. 27, 1914.

e of chlorophyll extracts as fuel. Fr. Pat. 466,985. *See* IIa.

XIXf.—WATER PURIFICATION ; SANITATION.

ter ; Removal of manganese from ——. J. Tillmans. J. Gasbeleucht., 1914, **57**, 713—724. (See also this J., 1914, 331).

eview of the methods used for the removal of manganese m drinking water, together with the results of an erimental investigation. The methods in use in ctice are filtration through manganese dioxide, or ough material containing it, and filtration through sand, h or without previous aeration ; in the latter methods may also be made of the biological activity of certain æ. Among the manganese-containing material cially suitable for filtration is a permutite containing % MnO_2 ; the latter removes the manganous hydroxide m the water, while the permutite itself accounts for acid radical ; after removal, the manganous hydroxide oxidised by the dissolved oxygen to the dioxide and acts as a fresh adsorbing surface. When complete eneration of the material is necessary, it can be brought out in the case of permutite by washing the filter with manganate, and in the case of ordinary manganese xide by washing with an alkali and blowing air through. he biological process, the manganese dioxide contained hin the algæ withdraws manganese by adsorption n the water and the vital processes of the organism lise it to the dioxide.—J. H. J.

ter ; Sterilisation of —— by filtration. K. Charitschkoff. Chem.-Zeit., 1914, **38**, 222.

eriments with filter paper impregnated with cobalt hthenate (see this J., 1910, 210) showed that all porous ies form hydrogen peroxide in presence of water. ilisation can be effected by passing water through ice, asbestos and other substances, and it is suggested oxidation takes place during the process.—J. H. J.

pipes for conveying water ; Use of ——. A. Rinck. Z. Untersuch. Nahr. Genussm., 1914, **28**, 99—103.

es of zinc were immersed in flasks of distilled water, water and water saturated with carbon dioxide, and quantities dissolved were determined colorimetrically r periods of 1 to 8 days. The amount of zinc dissolved eased, though not proportionately, with the time of act. After 1 day, 20 mgrms. per litre had been olved by distilled water, 12 mgrms. by tap water, 150 mgrms. by the carbonated water. After some ordinary water formed a deposit of basic carbonate the proportion dissolved was then much less. Tap r of medium hardness was sealed up in large zinc s with air excluded. After a year the amount of olved zinc was 2 to 3 mgrms. per litre. Physiological over a long period with water containing 7 to 8 mgrms. of zinc per litre gave no indications of injurious results. (See also this J., 1913, 957.)—C. A. M.

Potash trade-waste ; Influence of —— on the biological processes in river water. A. Muller and L. R. Fresenius. Arbeiten aus dem Kaiserlichen Gesundheitsamte, Berlin, 1913, **45**, pt. 4. Chem. Ind., 1914, **37**, 186—192.

A sewage percolating filter was used for the experiments, the changes taking place in the liquid passing through such a filter being similar to those taking place in the self-purification of rivers. To the sewage passed through the filter, known quantities of the waste lye were added, and the analysis of the effluent compared with that of the effluent from the filter without the addition of the lye. It was found that when the lye was added in quantity sufficient to raise the chlorine content of the mixture to 3 grms. per litre, there was no adverse influence upon the biological changes in the filter. A further increase of the chlorine to 6 grms. per litre diminished the nitrates in the effluent, while 20 grms. of chlorine prevented their formation altogether. No definite influence upon the oxygen absorption of the effluent could be detected. In partially purified sewage the addition of the lye delayed putrefaction, and on standing in contact, completely stopped it ; on diluting with clean water, putrefaction occurred as usual. The number of bacteria in the presence of 1·5 grm. of chlorine per litre was not influenced, but double the amount of chlorine caused a considerable reduction, and still higher amounts further reduction. The other forms of life present were not affected by 3 grms. of chlorine per litre, but 20 grms. prevented all life from developing. In cultivation experiments with pure cultures, the presence of chlorine up to 6 grms. per litre, slightly favoured nitrification, but over 7 grms. considerably reduced it. It is recognised that in a river water the addition of lye corresponding to 3 grms. of chlorine per litre does not interfere with its purification, but that double the amount does so. From these results it can be laid down as a guide for use in practice that the admission of lye to a river water so as to raise the amount of magnesium chloride to 3·5 grms. per litre is the danger point for all the lower forms of life in the river, but that from amounts even exceeding this, damage to fish is not to be expected. The interference of the waste lye with the self-purification of the river seems to exclude altogether the amounts entering in practice. —J. H. J.

Nickel cooking utensils. M. Vuk. Z. Untersuch. Nahr. Genussm., 1914, **28**, 103—104.

Discordant results obtained in experiments on the action of acids upon nickel cooking utensils are due to the nature of the nickel. Pieces of nickel of the same area were heated on the water-bath with 5% acetic acid for 2½ hours, and the quantities of metal dissolved per sq. m. were determined electrolytically, with the following results :—Wrought, 15·5 to 16·9 ; cast, 25·5 to 28·8 ; electrolytic, 30·6 to 30·8 ; drawn, 33·1 to 39·0, and Berndorf " pure " nickel, 61·4 to 65·4 mgrms.—C. A. M.

Ozone in ventilation. J. C. Olsen and W. H. Ulrich. J. Ind. Eng. Chem., 1914, **6**, 619—623.

A defence of the use of ozone in ventilation and a reply to papers by Jordan and Carlson and by Sawyer and others respectively (see J. Amer. Med. Assoc., Sept. 27, 1913). The view that ozone does not destroy odorous substances but merely masks their odour has been based on experiments in which the quantities of ozone used have been far too small, this being due mainly to the fact that the odour of ozone is at least 100 times more intense than that of other substances having a pronounced odour. Experiments are described showing that ozone oxidises hydrogen sulphide and oil of cloves. Moist bacteria are quickly destroyed by ozone even in low concentrations, and the works of Chapin, Doty, and Winslow and Robinson have shown that infection from air-borne bacteria occurs only when the latter are in a moist condition. No single instance of harm to a person from the proper use of ozone in ventilation has been published and all efforts to produce harm experimentally with low concentrations of ozone have failed.—A. S.

Physiological [*bactericidal*] *and physico-chemical action of neutral salts; Relation between the* ——. L. Berczeller. Biochem. Zeits., 1914, **66**, 173—190.

Experiments were made with Traube's stalagmometer (compare this J., 1911, 448; 1912, 839, 845) on the influence of salts on solutions of physiologically active substances. In unsaturated solutions of alcohol, phenol, thymol, menthol, camphor, quinol (hydroquinone), α-naphthol, sodium glycocholate, glycocholic acid, albumose, and casein, the surface tension was lowered to a greater extent in presence of dissolved salts than when these were absent. The physiological action of the substances mentioned is affected in a similar manner by salts, as is shown in the following table, in the case of the bactericidal action of phenol:—

Phenol solution.	Bactericidal action.	Lowering of surface tension.
Plus a neutral salt	greater (potassium salts less active than sodium salts, iodides less active than chlorides)	greater (potassium salts less active than sodium salts, iodides less active than chlorides)
Plus alcohol	lesser	lesser
Plus urea	no effect	no effect

The most satisfactory explanation of the results is one based on the assumption of the formation of hydrates of the salts, whereby a portion of the water is rendered inactive as a solvent. Sodium benzoate forms an apparent exception to the rule formulated above, for although it lowers the surface tension more than other salts, it is less effective in increasing the bactericidal action of phenol: this is probably due to the fact that sodium benzoate is itself strongly adsorbed and hence is capable of displacing adsorbed bactericides.—A. S.

Phenol; Action of —— *on the surface tension of albumin solutions.* L. Berczeller. Biochem. Zeits., 1914, **66**, 191—201.

The surface tension of serum and of solutions of different albumins, peptone, and ereptone is lowered to a greater extent than is that of distilled water by addition of phenol. *p*-Cresol and chloral hydrate produce a similar effect but not alcohol, propyl alcohol, triacetin and camphor. Since, according to Ehrlich and Bechhold (this J., 1906, 555) the bactericidal action of phenol is diminished by addition of serum, the rule that bactericidal activity and lowering of surface tension (see preceding abstract) vary in a similar manner appears not to hold in this case. If, however, from a solution of serum-albumin to which phenol has been added, the phenol be removed by passing the solution several times in a fine stream through benzene, the resulting solution has a considerably lower surface tension than before the addition of phenol, so that the lowering of the surface tension must be due not to the phenol, but to the serum-albumin or to a substance produced therefrom by the phenol. Moreover the lowering of the surface tension due to the phenol, *i.e.* the difference between the surface tensions of the solution of serum-albumin plus phenol and of the same solution after removal of the phenol, is somewhat smaller than that of aqueous phenol solution.—A. S.

Aluminium sulphate; Relation between —— *and colour in mechanical* [*water*] *purification.* F. E. Hale. J. Ind. Eng. Chem., 1914, **6**, 632—637.

As evidence in favour of the view that part of the organic colouring matter of natural waters is of an acid character, results are quoted showing that on precipitation with basic aluminium sulphate, the acidity produced was lower than that expected by an amount proportional to the colour removed. On blowing air through highly coloured water to remove carbonic acid, a residual acidity was left equivalent to the colour acidity; this residual acidity was not destroyed by boiling. When the colour acid was neutralised by sodium carbonate, a larger quantity of aluminium sulphate was required to effect decolorisation than before neutralisation. Commercial basic aluminium sulphate has an average composition corresponding to $2Al_2(SO_4)_3,Al_2(SO_4)_2(OH)_2$, and according to the alkalinity of the water, either a basic sulphate-carbonate, $2Al_2(CO_3)_2(OH)_2,Al_2(SO_4)_2(OH)_2$, or a basic aluminium carbonate is precipitated, the hydroxyl groups of which combine with the colour acid. The colour acid will also combine with other hydroxides, and good results have been obtained at Grand Rapids, Michigan, with excess of magnesium hydroxide. Regarding basic aluminium carbonate as the colour precipitant, the precipitate produced, at ordinary temperatures may be formulated as $Al_2(CO_3)_2R_2$, where R is the radical of the colour acid. At 100° F. (38° C.), a precipitate of $Al_2(CO_3)R_4$, is produced. double the quantity of colour being removed, and this is also the case if excess of basic aluminium sulphate over the quantity corresponding to the alkalinity of the water be used. At Springfield, Mass., U.S.A., for example, double the usual quantity of colour is removed per unit of precipitant by adding excess of aluminium sulphate, and after a definite period mixing with a further quantity of untreated water. At the boiling temperature, the colour is intensified by addition of aluminium sulphate, probably owing to the formation of a soluble compound, Al_2R_6, analogous to the known soluble iron compound.—A. S.

Pharmacological activity and lowering of surface tension. Berczeller. *See* XX.

Patents.

Water fed into steam generators; Apparatus for treating and removing amalgamated oil, grease and carbonates of lime and magnesia, sodium and the like held in suspension in —— *and for heating and softening and purifying such feed water.* J. Pomeroy, Southsea. Eng. Pat. 1103, Jan. 15, 1914.

The feed water flows down a series of inclined planes provided with cross baffles into a set of precipitating boxes. The apparatus is placed in the steam space of the steam generator and heated by the steam. The impurities collected in the bottom of the precipitating boxes are blown out of the boiler at intervals and the purified and heated water overflows into the water in the generator —W. H. C.

Garbage and sewage sludge; Method of treating ——. A. F Matlack, Philadelphia, Pa., Assignor to Sewage an Garbage Power Co. U.S. Pat. 1,102,532, July 7, 1914 date of appl., June 9, 1911.

The garbage or sludge is distilled at a temperature belo that at which the solid matters are charred, and t volatile products are collected and separated. The d residue is then treated in a gas-producer to convert it in a combustible gas and an ash which may be used as fertiliser.—W. P. S.

Elevating liquids [*e.g. sewage*]; *Process of and apparat for* ——. A. Priestman, New York. U.S. Pa 1,102,683 and 1,102,684, July 7, 1914; dates of ap April 27, 1912, and July 17, 1913.

The liquid (sewage) is fed into a settling well whence t liquid portion overflows into a second well. The liq is pumped out of the second well and the partially separat solids are elevated from the first well by an ejector work by compressed air and controlled by the height of level of the liquid in the second well.—W. H. C.

Disinfectant. Schülke und Mayr Akt.-Ges. and P. Flemmi Fr. Pat. 467,636, Jan. 22, 1914. Under Int. Co Jan. 24, May 6, and Oct. 16, 1913.

A mixture of chloro-xylenols and chloro-cresols or al compounds of the latter.—W. P. S.

Disinfectants. Schülke und Mayr Akt.-Ges., and Flemming, Hamburg, Germany. Eng. Pat. 25. Nov. 11, 1913.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

lorphine ; New test for —— *[and copper].* T. H. Olver. Chem. and Drug., 1914, **85,** 219.

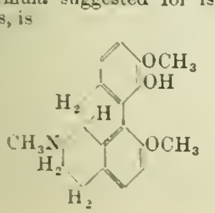
n adding a few c.c. of hydrogen peroxide and a small antity of strong ammonia solution to a solution of orphine or one of its salts, and stirring with a copper ire, gas is evolved and a deep port-wine coloration is oduced ; 0·00002 grm. of morphine can be detected by e test, but with very small quantities, a few drops of tassium cyanide must be added, after stirring, to destroy y blue colour due to copper. Monomethylamine may used in place of ammonia, but not dimethylamine nor ustic soda. Apomorphine gives an orange coloration der similar conditions, but codeine and dionine (ethylorphine), which are indistinguishable from morphine by dinary tests, do not give the reaction, nor do strychnine, ucine, atropine, narcotine, heroine, cocaine, nicotine, phaline, emetine, veratrine, physostigmine, pilocarpine, d coniine. Copper (0·00001 grm.) may also be detected the test.—A. S.

orphine and phenols ; Characterisation of —— by uranium alts. J. Aloy and C. Rabaut. Bull. Soc. Chim., 1914, **15,** 680—682.

LTS of uranium give a red coloration with morphine d with substances containing free phenolic (OH) groups. e reaction can be carried out by adding a crystal or few drops of a saturated solution of uranium nitrate acetate to the substance dissolved in water or in methyl ohol ; free acids must be absent. In cases where traces ly of morphine are suspected the liquid should be aporated to dryness. 0·05 mgrm. of morphine hydroloride can be detected.—R. G. P.

paver orientale ; Alkaloids of ——. W. Klee. Arch. Pharm., 1914, **252,** 211—273.

paver orientale contains two alkaloids, thebaine and a w crystalline alkaloid *isothebaine*, m. pt. 203°—204° C., $_D = -285·1°$ in alcohol. When the plant is in vigorous wth thebaine is the chief alkaloidal constituent, whilst er ripening and withering, the roots contain chiefly thebaine. Isothebaine is isomeric with thebaine and the formula $C_{17}H_{14}N(OCH_3)_2OH$, the nitrogen atom ng tertiary and attached to a methyl group. The stalline sulphate, hydrochloride and *l*-bitartrate were pared. When boiled with acetic anhydride isothebaine lded a diacetyl derivative with rupture of the nitrogen g, and with nascent diazomethane, a monomethyl ether formed. Methylation with dimethyl sulphate gave *hebainemethylethermethylsulphate*, crystallising from er-alcohol in needles, m. pt. 237°—238° C., $[\alpha]_D =$ 58·1°. This compound when boiled with caustic soda e two methine bases, *isothebainemethinemethylether*, orphous and optically inactive, and 9.10-*dihydroxy*-9-*ethylamino*-3.4.5-*trimethoxy*-8-*vinylphenanthrene*, m. pt. —105° C., $[\alpha]_D = -283·9°$. Both methine bases combd with dimethyl sulphate yielding *isothebainemethinehyletherdimethylsulphate* which crystallised in needles, pt. 195°—196° C., and was optically inactive. On ting with caustic soda in methyl alcohol this latter stance was decomposed into *trimethoxyvinylphenrene* and trimethylamine. Trimethoxyvinylphenanae on oxidation with potassium permanganate gave *trimethoxyphenanthrenecarboxylic acid* which when ted with glacial acetic acid gave the 3.4.5-trimethoxynanthrene previously obtained synthetically by horr and Koch (Annalen, 1912, **391,** 40). The conutional formula suggested for isothebaine, based on e reactions, is



Isothebaine gives a highly characteristic intense violet coloration with concentrated nitric acid. It can be separated from thebaine by heating the mixture with dilute hydrochloric acid, which converts thebaine into thebenine, insoluble in ether, but leaves isothebaine unaffected. It is considered that the alkaloids of *Papaver orientale*, unlike those of *Papaver somniferum* (Muller, Arch. Pharm., 1914, **252,** 280—293), do not serve as reserve stores of nitrogen to be subsequently used for albumin formation.—T. C.

Hydrastis alkaloids ; Determination of ——. J. Gsell. Chem.-Zeit., 1914, **38,** 511.

HYDRASTINE is precipitated from hydrastis extract with sodium hydroxide, and separated from the berberine (which remains in solution), by centrifugalising. Each alkaloid is then determined from the amount of methoxy-groups found by means of Benedikt's apparatus and method, viz., boiling the compound with hydriodic acid of sp. gr. 1·71. One grm. of hydrastine corresponds to 1·248 grm. AgI, and 1 grm. of berberine hydrochloride to 0·985 grm. AgI. The lactonic group in hydrastine is quantitatively separated, by boiling with $N/10$ sodium hydroxide solution under a pressure of 1 to 1½ atmos. One grm. of hydrastine = 26·4 c.c. $N/10$ alkali.—C. A. M.

Clematis vitalba ; Constituents of ——. F. Tutin and H. W. B. Clewer. Chem. Soc. Trans., 1914, **105,** 1845—1858.

THE flowering branches of *Clematis vitalba*, Linné ("traveller's joy" or "old man's beard") were dried, ground and extracted with hot alcohol. In addition to much chlorophyll and resin the extract yielded the following definite compounds : 3.4-dihydroxycinnamic acid, caulosapogenin, $C_{42}H_{66}O_6$, identical with the substance isolated by Power and Salway from *Caulophyllum thalictroides* (this J., 1913, 211), a *glucoside of caulosapogenin*, $C_{54}H_{86}O_{16}$, having the characters of a saponin, dextrose, myricyl and ceryl alcohols, hentriacontane, a mixture of sitosterol and stigmasterol, a phytosterolin consisting essentially of stigmasterol-glucoside, and a mixture of acids consisting of melissic, cerotic, palmitic and unsaturated acids including linolic acid and an acid, $C_{22}H_{44}O_2$, of m.pt. 69·5° C., isomeric with behenic acid. Some of the derivatives of caulosapogenin gave on analysis anomalous results. No alkaloid and only a trace of volatile substance could be detected. No confirmation of the alleged irritant properties of *Clematis vitalba* could be obtained.—T. C.

Anthemis nobilis [chamomile] ; Constituents of flowers of ——. F. B. Power and H. Browning, jun. Chem. Soc. Trans., 1914, **105,** 1829—1845.

21·09 kilos. of the ground flower-heads of *Anthemis nobilis*, Linné (chamomile) from plants grown in Belgium were extracted with hot alcohol, the alcoholic solution concentrated and the extract distilled in steam. 34·3 grms. of an essential oil were obtained but not further examined. The following compounds were isolated from the extract : 3.4-dihydroxycinnamic acid, apigenin $C_{15}H_{10}O_5$, a new *glucoside of apigenin*, $C_{21}H_{20}O_{10},H_2O$, m.pt. 178°—180° C., which gave a hexa-acetyl derivative, m.pt. 144°—146° C., choline, *i*-inositol, triacontane, taraxasterol, $C_{29}H_{47}\cdot OH$, m.pt. 217°—219° C., a phytosterolin consisting chiefly of sitosterol-*d*-glucoside, a mixture of fatty acids consisting of cerotic, stearic, palmitic, oleic and linolic acids, together with a considerable amount of a sugar yielding *d*-phenylglucosazone. The substances "anthemic acid" and "anthesterol" of previous investigators could not be confirmed. The bitter taste of chamomile flowers is due to dark-coloured amorphous material and not to any well-defined constituent.—T. C.

Podophyllum resin ; Method for the determination of ——. W. M. Jenkins. J. Ind. Eng. Chem., 1914, **6,** 671—672.

IN previous methods for the determination of Podophyllum resin (compare Dunstan and Henry ; this J., 1898, 268), it has been assumed that the resin is insoluble in water. The resin is, however, slightly soluble in water, and the solubility is increased even by small percentages of alcohol. A method is described based on the ready solubility of the resin in a mixture of 1 part of alcohol and 2 parts of chloroform. 5 c.c. of the fluid extract of Podophyllum are shaken with 5 c.c. of alcohol, 10 c.c. of chloroform, and 10 c.c. of acidulated water (0 6% HCl). The lower layer is drawn off and the aqueous solution extracted twice with 15 c.c. of alcohol-chloroform each time. The united extracts are washed with 10 c.c. of acidulated water, and the aqueous layer again shaken twice with 15 c.c. of alcohol-chloroform. The combined extracts are evaporated and the residue dried at 100° C. The drug is extracted with alcohol by hot maceration and 10 c.c. of the extract (=2 grms. of drug) are treated as described above, except that the addition of 5 c.c. of alcohol is omitted. A standard of 5% of resin for the fluid extract is suggested.—A. S

Pharmacolojical activity and lowering of surface tension. L. Berczeller. Biochem. Zeits., 1914, **66**, 202—206.

The results of the author's experiments confirm the view expressed by Traube (this J., 1912, 839) that there is a relation between the pharmacological activity of medicinal substances and their action in lowering the surface tension of water. Experiments were made with phenol, the di- and tri-hydroxybenzenes, aromatic hydrocarbons, vanillin, the cresols, the naphthols, thymol, menthol, camphor, *p*- and *o*-nitrophenol, *p*-, *m*-, and *o*-nitrotoluene, *m*- and *o*-toluidine, *p*- and *o*-nitrobenzaldehyde, chloralose and *p*-chloralose, phenanthrene and anthracene. Certain exceptions were observed: *e.g.*, quinol (hydroquinone) is more poisonous than resorcinol, but the latter causes the greater lowering of surface tension, and *o*-cresol is a better antiseptic than *m*-cresol although it has less effect on the surface tension.—A. S.

Essential oils free from terpenes and sesquiterpenes used in perfumery. H. Mann. Amer. Perfumer, 1914, **9**, 135—136.

The odorific intensity of terpeneless essential oils compared with the ordinary oils as unity was as follows:—Angelica root, 20; anise, 1½; star anise, 1½; bay leaves, 2½; bergamot, 2½; birchbuds, 2—3; birch tar, 10—12; cananga, 10—12; cassia, 1½; cedar wood, 8, chamomile, 1½—2; cinnamon, 1½; cinnamon leaves, 1½; citronella, 2—2½; celery, 3; cumin, 2—3; cypress, 30; eucalyptus, 1½; fennel, 2½—3; geranium, 1½; guaiacum wood, 1½; hops, 8—9; kuro-moji, 3—4; lavender, 1½—2; lemon, 30; lemongrass, 1½; lime (distilled), 12—15; lime (expressed), 8—10; linaloe, 1½; mandarin, 60; myrrh, 2½; myrtle, 3—4; neroli, 2½; nutmeg, 6—8; opopanax, 4—6; orange (sweet), 60; (bitter), 60; origanum, 1½; patchouli, 4—5; peppermint, 1½; petitgrain, 1½; pimento, 1½; pine (leaves) 3—4; cones (*A. pectinata*), 60; leaves (*A. pectinata*), 60; rose, 1½; rosemary, 2; sandalwood, 1¾—4; thyme, 4—5; vetiver, 1½; and ylang-ylang, 2—2½. Terpeneless lemon oils are used in the preparation of cheap eau-de-cologne since their alcoholic solution can be diluted with more water than in the case of the ordinary oil without becoming turbid.—C. A. M.

Cedar wood; The oil of Port Orford —— and some observations on d-a-pinene. A. W. Schorger. J. Ind. Eng. Chem., 1914, **6**, 631—632.

The Port Orford cedar [*Chamaecyparis lawsoniana* (Murr.), *Parlatore*] is found along the Pacific Coast from Coos Bay, Oregon, to Mad River, California. The oil obtained from the wood has a strong pleasant odour and a pronounced physiological action on the kidneys. Selected "resinous" pieces of wood yielded, by steam distillation, 10% of oil of sp. gr. 0·891 at 15° C., $n_D^{15}=1{\cdot}477$; the oil left a blood-red distillation residue. The oil examined by the author had been kept for four years in a tightly-stoppered bottle. It was rectified by shaking with 10% sodium carbonate solution and distilling with steam over soda solution: the rectified oil left no blood-red residue on distillation and did not produce the characteristic physiological action of the freshly-distilled oil. The rectified oil had the sp. gr. 0·8905 at 15° C., $n_D^{15}=1{\cdot}4758$, $a_D^{25}=+39{\cdot}60°$, acid value 0·30, ester value 32·8, ester value after acetylation 71·57, and gave the following fractions on distillation: 155°—157° C., 60·5; 157°—170°, 3; 170°—180°, 4; 100°—130° at 15 mm., 20·5; 130°—160° at 15 mm., 7; and 160°—190° C. at 15 mm., 1%. It contained approximately 60—61% of *d-a*-pinene, 6—7% of dipentene, 11% of free *l*-borneol, 11·5% of esters (calculated as bornyl acetate), and 6—7% of cadinene. The combined borneol was present mainly as bornyl acetate, but to some extent also as formate and caprinate. In the old oil free formic, acetic, and caprinic acids were present. By fractionation over sodium the fraction distilling at 155°—157° C. yielded 65% of its quantity of pure *d-a*-pinene of b.pt. 156°—156·1° C. at 760 mm., sp. gr. 0·8631 at 15° C., $n_D^{15}=1{\cdot}4684$; $[a]_D = +51{\cdot}52$.—A. S.

Cus-Cus [vetivert] oil of India. P. Singh. Chem. and Drug., 1914, **85**, 225—256.

Seven samples of roots of vetivert (Cus-Cus or Khas-Khas grass, *Andropogon muricatus*, Retz) from different localities in India were examined as to yield of oil, 25 grms. being distilled with steam for about 3 days, and the oil extracted from the distillate with chloroform. The yield of oil was from 0·45 to 1·14%, varying according to the season in which the roots were collected. To obtain a good yield of oil (0·7—1%) the roots should be collected from towards the end of the winter till the commencement of the rainy season. A sample of the oil was purified by re-distillation with steam, leaving as residue a resinous mass from which, by extraction with alcohol, there was isolated a dark red resin (9·4 grms. from 75 grms. of oil) of m.pt. 70° C., sp. gr. 1·132 at 30° C., acid value 46·9, saponif. value 111·2, iodine value (Hübl, 18 hours) 268·2, optical rotation (calculated to 10 c.c. of solid resin from observation with a dilute solution), +488. The yellowish brown redistilled oil was quite transparent and had the following characters: sp. gr. 1·011 at 15° C., optical rotation (100 mm. tube) —30·7, $n_D^{20}=1{\cdot}5165$, acid value 10·5, saponif. value 80·1, saponif. value after acetylation 132·8, iodine value (Hübl, 18 hours) 194·4, soluble in 2 parts of 80% alcohol.—A. S.

Esters; Determination of —— in essential oils. J. Niviere Bull. Soc. Chim. 1914, **15**, 677—680.

The author criticises Béhal's recommendation that ester should be saponified in closed vessels (this J., 1914, 765) Concordant results were obtained by saponification i an open flask fitted either with an air tube or a reflu condenser. Higher results were obtained with close flasks than with open flasks, *e.g.*, lavender oil gave saponification value of 114·2 in an open flask and 117 in closed flask; bergamot oil, open flask 104·1, closed flas 150·7. Pure linalyl acetate gave practically identica results either in open or closed flasks, viz., 242, but linal acetate containing 2% of œnanthol gave saponificatio values, open flask 239·8—239·9; closed flask 241·7—24 The differences therefore appear to be due in part to th presence of aldehydes and not to the loss of volatil esters.—R. G. P.

Salicylic acid [and acetylsalicylic acid and salol]; Man facture of ——. Chem. and Drug., 1914, **85**, 313—31

Salicylic acid. In Kolbe's process, the patent f which expired in 1887, crystallised phenol is dissolved the equivalent quantity of caustic soda, the soluti is evaporated in shallow iron vessels, with vigoro stirring, and the reddish-yellow, very hygroscopic sodiu phenoxide thus obtained is ground and heated to 100° in a metal retort; the mass is constantly stirred a subjected to the action of a rapid current of dry heat carbon dioxide. The temperature is raised gradual in the course of several hours to 180° C.; phenol dist over, at first in small quantity, later more abundantl The mass is heated finally to 200° C., and after 6—8 hou when no more phenol distils over, the greyish white resid is dissolved in water, resinous and coloured impurities a separated by fractional precipitation with hydrochlor or sulphuric acid, and the salicylic acid is then precipitated by addition of more mineral acid. (See also Thorpe Dictionary of Appl. Chem., 1913, Vol. IV., p. 619)., Potassium phenoxide is now usually employed instead of the sodium compound (compare Eng. Pat. 17,002 of 1893; this J., 1893, 1055), and a modified process is also used, in which carbon dioxide under pressure is used at 120°—145° C. (See Eng. Pats. 10,167 of 1884 and 7801 of 1886; this J., 1885, 551; 1886, 501). The acid is purified from cresotic acid by Williams' process (see G. G. Henderson, this J., 1890, 591), a hot aqueous solution being neutralised with calcium carbonate, and the calcium salicylate filtered off, recrystallised from hot water till colourless, decomposed with hydrochloric acid, and the precipitated acid washed with water and recrystallised from dilute alcohol. It is difficult to obtain a product of permanent pearl-white appearance, details of certain stages of the purification and of the final crystallisation being secret.

Acetylsalicylic acid (*aspirin*). No patent rights cover the manufacture of acetylsalicylic acid, two methods for which are as follows:—(1) A mixture of 50 parts of salicylic acid and 75 parts of acetic anhydride is heated for 2 hours at 150° C. under a reflux condenser. On cooling, acetyl salicylic acid crystallises; it is freed from acetic anhydride by pressing, and recrystallised from dry chloroform, yielding white needles, m. pt. 135° C., readily soluble in benzene, alcohol, glacial acetic acid and chloroform, soluble with difficulty in cold water. (2) A mixture of 25 parts of salicylic acid and 20 parts of acetyl chloride is heated for several hours at 80° C. under a reflux condenser, then the excess of acetyl chloride is distilled off, and the residue recrystallised from dry chloroform.

Salol (*phenyl salicylate*) is produced by treating salicylic acid and phenol with phosphorus pentachloride or oxychloride. The process of manufacture was patented in England in 1886 (see Eng. Pat. 8018 of 1886; this J., 887, 561; also Levinstein, this J., 1886, 577), and the patent rights (now expired) were transferred to German firms. (See also Eng. Pats. 10,260 of 1887, 14,224 of 1891, and 23,449 of 1892; this J., 1888, 587; 1891, 1026; 894, 274.)—A. S.

Acetanilide and phenacetin in admixture; Determination of ——. Studies in synthetic drug analysis. I. W. O. Emery. J. Ind. Eng. Chem., 1914, **6**, 665—669.

The method proposed depends on the fact that phenacetin in aqueous solution forms an insoluble periodide $C_2H_5O.C_6H_4.NH.C_2H_3O)_2.HI.I_4$, when treated with an acid solution of iodine in potassium iodide. 0·2 grm. of the sample is dissolved in 2 c.c. of hot glacial acetic acid in a small lipped Erlenmeyer flask, the solution is diluted with 40 c.c. of water previously warmed to 70° C., transferred to a stoppered 100 c.c. flask containing 25 c.c. of standard iodine solution (30 grms. of iodine and 40 grms. of potassium iodide per litre) warmed to 40° C., two 10 c.c. portions of warm water being used for rinsing. After mixing, 3 c.c. of concentrated hydrochloric acid are added: the insoluble periodide separates at first apparently in an emulsified condition, but after some time forms bronze-coloured leaflets. When the crystals have formed, the mixture is allowed to cool, diluted with water to 97—98 c.c., allowed to stand overnight, made up to 100 c.c., mixed, allowed to settle for ½ hour, and a portion of the solution filtered through a dry 5·5 cm. filter: the first 15 c.c. are collected separately, and then 50 c.c. are collected and the excess of iodine titrated with $N/10$ thiosulphate. Or, the periodide may be filtered off, decomposed by means of sodium sulphite, the phenacetin extracted with chloroform and weighed. In the filtrate from the phenacetin periodide, acetanilide may be determined by adding sodium sulphite to remove free iodine, extracting the acetanilide with chloroform, hydrolysing it with sulphuric acid, and titrating the resulting aniline sulphate with potassium bromide-bromate solution. In the case of complex mixtures containing caffeine or antipyrine or both, the sample is first digested with hot dilute sulphuric acid, the caffeine and antipyrine then removed by extraction with chloroform, and the sulphates of phenetidine and aniline present in the acid aqueous solution re-converted into phenacetin and acetanilide respectively by adding a slight excess of solid sodium bicarbonate and a few drops of acetic anhydride (Proc. A.O.A.C., U.S. Dept. Agric., Bureau of Chem., Bull. 162 (1912), 197).

The formation of the insoluble periodide may also be used as a test capable of detecting 0·5 mgrm. of phenacetin. —A. S.

Manufacture of antipyrine. Chem. and Drug., 1914, **85**, 273.

The following are the steps in the method of making antipyrine:—

1. *Formation of phenylhydrazine from benzene.*—Benzene is converted into nitrobenzene by the action of concentrated nitric acid, then reduced to aniline by nascent hydrogen formed by the action of hydrochloric acid on scrap iron. The aniline is diazotised with nitrous acid, and a paste of stannous chloride is added to the clear, mobile, brown diazo-solution which becomes creamy white and so stiff that it can only just be poured. A couple of hours' standing ensures complete reduction; neutralisation with caustic soda follows, and the phenylhydrazine formed is then distilled under reduced pressure.

2. *Preparation of aceto-acetic ethyl ester.*—This is accomplished by the action of metallic sodium upon ethyl acetate followed by treatment with acetic acid. The ethyl acetate is obtained by acting upon sodium acetate with a mixture of alcohol and sulphuric acid. Ethyl alcohol added in small portions to sulphuric acid produces ethyl sulphuric acid. This is poured upon dried fused and broken pieces of sodium acetate previously placed in a copper still. After standing twelve hours the contents of the still are raised to the boiling-point, in order to form ethyl acetate, which distils over. The collected distillate is then freed from water by redistilling over calcium chloride. In order to form aceto-acetic ethyl ester, the ethyl acetate with small pieces of metallic sodium drawn into wire are placed in a still having a reflux condenser and left until the sodium has disappeared, after which a moderate excess of 50% acetic acid is added and the contents agitated. On standing, the contents separate into two layers, the upper one of which is subjected to fractional distillation, and the portion which passes over between 175° and 185° C. collected.

3. *Condensation of phenylhydrazine and aceto-acetic ethyl ester to form phenyl-methyl pyrazolone.*—When the phenylhydrazine and the ester are mixed in the proportion of 1 to 1·3 the solution boils vigorously; globules of water separate and float through the mass of the liquid, which rapidly changes in colour from light yellowish-brown to reddish-brown. Upon warming this over a water-bath for a couple of hours the liquid darkens and thickens until it can only just be poured. During the heating alcohol is eliminated, a second condensation takes place, with formation of the pyrazolone ring. After removal of the alcohol and water, the dark, thick fluid is stirred, and poured while warm into a little over its own volume of ether. In a few minutes reddish particles begin to separate, and soon solidify into a dark-reddish crystalline magma insoluble in ether. This mass is allowed to stand until cold, when it is filtered and washed very thoroughly with ether until it forms a white crystalline powder.

4. *Methylation of the pyrazolone compound and the formation of antipyrine.*—This is accomplished by taking equal weights of freshly distilled methyl iodide, pyrazolone, and methyl alcohol, mixing them together in sealed glass pressure tubes, and heating to 100° C. in a bomb-furnace that allows of careful regulation. The temperature must not go much above 100° C., or there will be great danger of explosion from excessive internal pressure due to sudden liberation of vapours produced by decomposition. At the end of three hours the containers are allowed to cool. When the tubes from the furnace have thoroughly cooled, the contained hydriodide solution is removed into an open vessel. In order to avoid spattering, care must be taken in opening the tubes to allow the internal pressure to be relieved gradually. Water and sulphurous acid are next added, and the solution boiled until most of the methyl alcohol has been driven off. The sulphurous acid acts upon the hydriodic acid, forming free

iodine, sulphur, water, and basic 1-phenyl-2·3-dimethyl-5-pyrazolone (antipyrine). The chloroform solution is evaporated to a paste and just sufficient warm toluene added to dissolve it. Upon slowly cooling the antipyrine crystallises out. According to Riedel, the production of antipyrine upon a commercial scale involves but one operation for condensation and methylation. He states that phenylhydrazine 100 parts, aceto-acetic ethyl ester 125 parts, sodium methylsulphonate 150 parts, sodium iodide 150 parts, hydriodic acid 5 parts, and methyl alcohol 100 parts are heated to 160° to 180° C. in an autoclave under a pressure of twelve to fifteen atmospheres for ten hours. A still later report states that the sodium iodide is not necessary in this process, provided four to five times the above-quoted amount of hydriodic acid be used. The contents of the autoclave are taken up with a mixture of alcohol and ether, filtered, and washed, thus separating the antipyrine from the by-product—sodium sulphate. The alcohol and ether are distilled off, the residue dissolved in water and made alkaline, the solution extracted by chloroform, the chloroform distilled off, and boiling toluene added, from which, on cooling, the antipyrine crystallises.

The cost of the ingredients for antipyrine is given as, roughly, 3s. 6d. per lb., this being based on the production of 100 tons per annum.

Dimethylenediol peroxide (*Diformal peroxide hydrate*). H. J. H. Fenton. Roy. Soc. Proc., 1914, A, **90**, 492—498.

When a mixture of concentrated solutions of formaldehyde and hydrogen peroxide is further concentrated *in vacuo* over sulphuric acid a brilliant crystalline mass is obtained having the molecular formula, $H_2O_2.2H.CHO$. The compound is remarkably stable at low temperatures in the dark, and it dissolves unchanged in water and in acetic acid. It gives the normal molecular weight by the cryoscopic method, and this value remains constant in aqueous solution even after 48 hours at 0° C. When the crystals are heated to about 70° C. they explode, and they take fire spontaneously in contact with reduced iron or platinum black. They decompose slowly in bright sunlight. Treatment of the aqueous solution with platinum black causes rapid evolution of oxygen and a pure solution of formaldehyde remains. The general behaviour of the substance leads to the conclusion that it is not one containing hydrogen peroxide of crystallisation but rather an "atomic" compound in the ordinary sense of the term.—W. H. P.

Grignard reagent ; Oxidation of the ——. E. Ferrario. Chem.-Zeit., 1914, **38**, 794.

The oxidation with sodium or barium peroxide proceeds according to the schemes: (1) $R.MgBr+O=R.OMgBr$; (2) $(RMgBr)_2+O=R.R+O(MgBr)_2$. The relative amounts of hydrocarbon, R.R, and of alcohol or phenol, R.OH, produced depends on conditions. In the aromatic series with sodium peroxide the hydrocarbon predominates, whilst in the aliphatic series the reverse is the case. Better results were obtained by this method than by using atmospheric oxygen as oxidising agent according to the method of Boudroux.—G. F. M.

a-Bromonaphthalene : its physical properties and its application to the determination of water in moist alcohol. M. Jones and A. Lapworth. Chem. Soc. Trans., 1914, **105**, 1804—1809.

a-Bromonaphthalene is purified by fractional distillation of the commercial article in steam and crystallisation of the distillation residue from absolute alcohol at a low temperature; the product is freed from alcohol by a current of steam and from water by treatment first with calcium chloride and then with a stream of dry air or carbon dioxide at 100° C. The compound is dimorphous; the stable modification melts at 6·20° ± 0·02° C. and has sp. gr. at 20°/4° C., 1·4834; the other melts between 0° and 2° C. The refractive index is $n^{20}_{D}=1{\cdot}6582$. The pure compound may be used for determining water (up to 10%) in moist alcohol, known quantities of bromonaphthalene and alcohol being mixed, the solution slowly cooled until it becomes opaque, and the temperature noted with a sensitive thermometer; an opalescence which first appears is easily distinguished from the opacity at the critical point. A table is given showing the temperatures of clouding of various mixtures.—L. E.

Phenolphthalein ; New method for the determination of ——. A. Mirkin. Amer. J. Pharm., 1914, **86**, 307—308.

One grm. of phenolphthalein, 0·8 grm. of hydroxylamine hydrochloride, both finely powdered, and 0·52 grm. of 90% sodium hydroxide are dissolved in 35—40 c.c. of absolute alcohol, and boiled in a reflux apparatus for 2 to 3 hours, when the liquid should be yellow. The liquid is diluted with water, 10 c.c. of 10% sulphuric acid added and the whole made up to 250 c.c. 50 c.c. are made neutral to methyl orange and then the excess of hydroxylamine is titrated with *N*/10 potassium hydroxide using phenolphthalein as indicator. A control test is carried out using the above quantities and omitting the phenolphthalein. The difference in the number of c.c. of *N*/10 potassium hydroxide multiplied by 316 gives the quantity of phenolphthalein.—F. Shdn.

Mercuric benzoate. E. Rupp and A. Herrmann. Arch. Pharm., 1914, **252**, 3.

Normal mercury benzoate, official in the French Pharmacopœia, has been recommended as the most suitable salt for hypodermic injection. The method of the French Pharmacopœia for preparing it, by precipitation from sodium benzoate and a mercuric salt, is the best; it cannot be recrystallised from water, as one part is only soluble in 230 at boiling point, and it undergoes partial hydrolysis. When dissolved with the aid of sodium chloride, as in making the hypodermic injection, double decomposition occurs, the solution contains sodium benzoate and mercuric chloride, and the latter can be shaken out with ether; the solution usually recommended, mercuric benzoate, 1·0; sodium chloride, 0·75; water, 100, is identical with one prepared from mercuric chloride, 0·59; sodium benzoate (cryst.), 0·72; sodium chloride, 0·5; water, 100. The solubility of the salt on the addition of ammonium benzoate is due to the formation of a mercuri-ammonium complex. The effect of mercuric benzoate solution on albumin is exactly the same as that of a solution of mercuric chloride containing the same amount of sodium chloride; sufficient of the latter prevents precipitation of albumin in any case.

Colloid-chemical studies. [*Colloidal selenium for use in medicine.*] A. Gutbier. Chem.-Zeit., 1914, **38**, 295. (See also this J., 1911, 1318.)

By the use of hydrazine hydrate as reducing agent the author has produced colloidal preparations of arsenic, antimony, selenium, mercury, silver, platinum, palladium, gold, etc., of high concentration and great stability, and readily soluble in water. Colloidal selenium is now prepared on a commercial scale for use in medicine. It does not give rise to the unpleasant secondary effects produced by other selenium preparations.—A. S.

Lanthanum from a physiological-chemical standpoint. T. Bokorny. Chem.-Zeit., 1914, **38**, 153—154.

Experiments on algæ and yeast showed that lanthanum, although so closely resembling calcium in chemical attributes, is in no way similar in physiological action. Not only was it impossible to replace calcium nitrate by lanthanum nitrate in culture solutions, but lanthanum was found to be an active poison, especially towards plants containing chlorophyll.—F. Sodn.

Mineral] Oils [for medicinal purposes], Treatment of ——. L. C. Wallach, London. Eng. Pat. 15,551, July 5, 1913.

ineral oil, for example highly refined white mineral oil *paraffinum liquidum*, is exposed to, and allowed to sorb, the emanations from radio-active substances. ee also Eng. Pats. 14,885 of 1905, 11,988 of 1908, and 78 of 1911; this J., 1911, 1115).—A T. L.

nsaturated organic compounds; Manufacture of ——. F. E. Matthews, H. J. W. Bliss, and H. M. Elder, London. Eng. Pat. 16,828, July 22, 1913. Addition to Eng. Pat. 17,234, July 24, 1912 (see this J., 1913, 884).

he principal patent described the removal of the elements halogen acids from halogenated hydrocarbons by means water or steam. It is now found that this process is plicable to the removal of halogen acid from other logenated organic compounds. Such compounds are eated with steam at a temperature between 100° and 0° C., with or without the use of a catalyst. In some ses it is advantageous to subject the mixed heated pours to the action of the silent electric discharge or ultra-violet light. The following example is given:—ne hundred grms. of β-bromohydrocinnamic acid is spended in water and introduced gradually into a silica be heated to 600—650 C.; hydrobromic acid and rbon dioxide are split off and styrolene is formed, which isolated by steam distillation and fractionation. The changed bromohydrocinnamic acid is recovered and ain passed through the silica tube.—T. F. B.

ridine carboxylic acids and pyridine; Manufacture of ——. A. Heinemann, London. Eng. Pat. 17,003, July 24, 1913.

omologues of pyridine, the phenylpyridines, and inolines can readily be oxidised to pyridinecarboxylic ids by means of ozone, ozonised oxygen, or ozonised air, the ordinary temperature. The ozone can be passed to a vessel containing the pyridine derivative, or it can generated electrolytically at the anode of an electro-ic cell, in which the pyridine derivative is oxidised; in is case it is advisable to surround the cathodes by aphragms to prevent reduction of the carboxylic acids. hen it is desired to prepare pyridine, the carboxylic acid distilled, and, if necessary, the oxidation process is eated until the product consists of pure pyridine.—T. F B.

oculating substances from bacteria; Process for preparing efficacious ——. S. Sokal, London. From Kalle und Co. Akt.-Ges., Biebrich on Rhine, Germany. Eng. Pat. 22,288, Oct. 3, 1913.

e "opening up" of bacteria by means of dilute acids, th or without addition of lecithin, can be considerably celerated by adding a small quantity of common salt the acid solution. For example, 50 grms of paratyphoid cilli are finely ground and digested at about 60° C. th one litre of a solution containing 0·5% of lactic acid d 0·85% of common salt. After two to three weeks formation of flakes is sufficiently complete, and the ar liquid can be separated from the residue by filtration centrifuging. In this case the residue is used for rapeutic purposes. With other bacteria, *e.g.*, with htheria bacilli, the filtrate possesses a high immunising wer. The preparations obtained in this way are highly cient, and do not exhibit the unpleasant effects perienced with inoculations with "complete" bacteria. e residues obtained by this "opening up" process be separated by extraction with alcohol and then h ether, into three portions, *viz.*, a mixture of fatty ds and lipoids, neutral fat and wax, and the insoluble teria bodies (albuminous substances). These different stituents can be made into solutions of any desired concentration, and mixed in suitable proportions for inoculating purposes.—T. F. B.

Therapeutic compounds [aminophenylselenonic acid, etc.]; Manufacture of ——. H. S. Wellcome, London, and F. L. Pyman, Dartford. Eng. Pat. 2787, Feb. 3, 1914.

Phenylseleninic acid or its nitrate is converted by nitration with sulphuric acid and potassium nitrate into a nitrophenylseleninic acid, $NO_2.C_6H_4.SeO_2H$, of m. pt. 156°—157° C. This is converted by reduction with sodium bisulphite into nitrophenyldiselenide, $NO_2.C_6H_4.Se.Se.C_6H_4.NO_2$, of m. pt. 83 C.; reduction of the diselenide with sodium sulphide results in the production of the aminophenyldiselenide, which forms a crystalline hydrochloride, of m. pt. 291—292° C. Acetaminophenyldiselenide, m.pt. 185—186° C. is obtained by treating aminophenyldiselenide with acetic anhydride; when oxidised with nitric acid it is converted into acetaminophenylseleninic acid, m. pt. 209 C., whilst further oxidation of this with permanganate in alkaline solution results in the formation of salts of acetaminophenylselenonic acid. The free acid is converted into aminophenylselenonic acid, $NH_2.C_6H_4.SeO_3H$, m.pt. 229 C., by boiling with water. This acid can be combined with alkalis and forms crystalline salts. The acid and its salts are said to possess "valuable physiological properties."—T. F. B.

Quinoline-4-carboxylic acids arylated in the 2-position; Manufacture of ——. Chem. Fabr. auf Actien, vorm. E. Schering, Berlin. Eng. Pat. 11,836, May 13, 1914. Under Int. Conv., Aug. 1, 1913. Addition to Eng. Pat. 15,684 of 1912, dated July 5, 1911 (see this J., 1912, 953).

Largely increased yields of the 2-arylquinoline-4-carboxylic acids are obtained by adding less than one mol. of pyroracemic acid to a boiling alcoholic solution of one mol. of benzylidene-aniline or other condensation product of an aromatic amine and an aromatic aldehyde. The best results are usually obtained when about three mols. of pyroracemic acid are used to four mols. of benzylidene-aniline. The solution of pyroracemic acid is preferably added cold (*e.g.*, at 0° to 5° C.), and it is not necessary to use the pure acid. Further, the process can be carried out without decreasing the yield, if dilute alcohol be used as the solvent; in this case the 2-phenylquinoline-4-carboxylic acid, for example, crystallises quantitatively from the solution on cooling. The yields obtained correspond to about 180—185% of the pyroracemic acid used, when benzylidene-aniline is employed.—T. F. B.

Diethylacetylisocyanate. J. Callsen, Elberfeld, Germany. Assignor to Synthetic Patents Co., New York. U.S. Pat. 1,098,938, June 2, 1914. Date of appl., Dec. 12, 1913.

Diethylacetyl isocyanate, $(C_2H_5)_2CH.CO.N:CO$, is obtained by treating diethylacetyl chloride or bromide with a silver or mercury salt of isocyanic acid. It is a limpid oil of b. pt. 67°—72° C. at 50 mm. pressure; it is soluble in petroleum spirit and benzene, and yields diethylacetylurea when treated with ammonia.—T. F. B.

Beta-acetylalkylene-tetra-alkyldiamines. G. Merling and O. Chrzescinski, Elberfeld, and H. Köhler, Leverkusen, Assignors to Farbenfabr. vorm. F. Bayer und Co., Elberfeld, Germany. U.S. Pat. 1,101,754, June 30, 1914. Date of appl., June 5, 1913.

The β-acetylalkylene-tetra-alkyldiamines,

$$CH_3.CO.CR(CH_2.NR'_2)_2,$$

when R represents hydrogen or alkyl and R′ alkyl, are colourless, odourless oils, soluble in water, which are valuable intermediate products for making erythrene or its homologues. They may be prepared by the two-fold introduction of the residue, $CH_2.NR'_2$, into the corresponding ketone, and can be separated from the monoamines by fractional distillation. $\beta\beta$-Acetylmethyltrimethylenetetraethylenediamine,

$$CH_3.CO.C(CH_3)[CH_2.N(C_2H_5)_2]_2,$$

is obtained by adding gradually 292 parts of a 50%

aqueous solution of diethylamine to 75 parts of aqueous 40% formaldehyde, adding 210 parts of methylethylketone, and boiling the mixture under a reflux condenser for several hours, until a test portion, after acidification with acetic acid, does not become turbid on adding a solution of aniline acetate. The solution is then dehydrated over potash, the excess of ketone removed by distillation *in vacuo*, and the remaining mixture of bases separated by fractionation *in vacuo*, the desired product having a b. pt. of 105°—110° C. at 7 to 8 mm. β-Acetyltrimethylenetetraethylenediamine, prepared in a similar manner, boils at 90°—110° C. at 7 to 8 mm.—T. F. B.

Organic iodine compounds; Preparation of ——. J. Sander. Ger. Pat. 275,441, March 1, 1913.

Saponin is heated with iodine in presence of water. Easily soluble compounds, suitable for therapeutic purposes, are obtained.—T. F. B.

Cyanhydrins of aldehydes and ketones; Preparation of derivatives of ——. A. Albert. Ger. Pat. 275,442. March 5, 1913. Addition to Ger. Pat. 259,502 (see this J., 1913, 673).

Cyanhydrins of aldehydes or ketones are converted into acyl derivatives and treated with hydrogen selenide in presence of an alcohol. The resulting compounds are esters of selenamidines: for example, the compound, $CH_3 \cdot CO \cdot O \cdot C(CH_3)_2 \cdot C(:NH)SeC_2H_5$, is obtained by treating the cyanhydrin of acetylacetone with hydrogen selenide and ethyl alcohol. (See also Ger. Pat. 273,053; this J., 1914, 667.)—T. F. B.

Organic mercury compounds; Process for preparing ——. E. Schossberger and G. Friedrich. Ger. Pat. 275,932. May 22, 1912.

Free terpenic keto-carboxylic acids or their esters react quantitatively with mercury salts, forming stable compounds which are soluble in alkalis and do not split off mercuric oxide on heating. The compound from camphorcarboxylic acid and mercuric acetate contains about 44% Hg. The products are suitable for use in medicine.—T. F. B.

Bismuth gallocarboxylate; Process for preparing basic ——. Farbenfabr. vorm. F. Bayer und Co. Ger. Pat. 276,072, Aug. 1, 1913. Addition to Ger. Pat. 268,932.

A salt, identical with that obtained according to the principal patent (see this J., 1914, 277), is obtained by the action of a basic bismuth salt or bismuth hydroxide on gallocarboxylic acid in presence of alkali.—T. F. B.

Hydrogenation or reduction. A. Brochet, Paris. Eng. Pat. 16,936, July 23, 1913. Under Int. Conv., July 27, 1912.

See Fr. Pat. 458,033 of 1912; this J., 1913, 1031. Reference is directed in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pats. 2520 of 1907, 3752 of 1910, 25,326 of 1911, and 72 of 1912.—T. F. B.

Auric compounds from cantharidylethylenediamine and process of making same. G. Spiess, Frankfort, and A. Feldt, Oberursel, Germany. U.S. Pat. 1,104,149, July 21, 1914. Date of appl., July 28, 1913.

See Ger. Pat. 269,661 of 1912; this J., 1914, 375.—T. F. B.

Camphene and isobornyl acetate; Process of producing a mixture of —— from pinene hydrochloride. C. Ruder, Wandsbek, Germany. U.S. Pat. 1,105,378, July 28, 1914. Date of appl., Feb. 13, 1913.

See Fr. Pat. 453,992 of 1913; this J., 1913, 884.—T. F. B.

Amyl acetate and its homologues; Method of producing ——. F. Kaufler, Brückl, Austria-Hungary. U.S. Pat. 1,106,047, Aug. 4, 1914. Date of appl., Feb. 8, 1913.

See Eng. Pat. 2779 of 1913; this J., 1913, 767.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Patent.

Colour photographs and process for their production. F. E. Ives, Woodcliffe-on-Hudson, N.J., U.S.A. Eng. Pat. 17,799, Aug. 2, 1913. Under Int. Conv., Aug. 5, 1912.

See Fr. Pat. 461,078 of 1913; this J., 1914, 44.—T. F. B.

XXII.—EXPLOSIVES; MATCHES.

Accidents and injuries to life and limb in explosives works, etc., in Germany. Chem. Ind., 1914, **37**, [14] (Beilage). 29—31.

Three explosions in dynamite factories were attributed respectively to the dropping of a wooden stemmer, used in making dynamite cartridges, which contained absorbed nitroglycerin, to an unknown cause in the case of an after-separating plant, and to the dropping of a box of finished dynamite in an incorporating house. In the last case, a pipe 80 metres long was detonated up to a flange at the filter-house, from which it conveyed nitroglycerin; a ferro-concrete tunnel showed weakness due to the want of lateral tying of the round iron rods with which the concrete was reinforced. The removal of a stoneware wash-water pipe caused an explosion at a nitroglycerin factory. The premature explosion of a dynamite cartridge connected to the leads ready for firing, on the testing-ground of a dynamite factory, was caused by lightning. An experimental nitroglycerin powder fired in the press, because it had been locally over-heated during rolling or in the press, or was ignited by the residue of a previous batch. The accumulation of a static charge in a zinc-lined cupboard in which strands of nitrocellulose powder were hung to dry, produced a spark which fired the ether vapour from the powder. No cause could be assigned to a case of firing of a rolled-sheet of propellant when being placed in the press. Two accidents in black powder mills were caused respectively by the accumulation of powder dust in mill-gearing, which in future will be placed outside the house, and to the overloading of a granulating machine, with consequent slipping and heating of the belt, on which was powder dust. In consequence of an explosion in a detonator factory the transference of detonators to the sieve for the removal of sawdust will in future be effected mechanically from outside. An explosion in an ammunition factory was caused by the dropping of a packet of rim-fire cartridges on another packet Carelessness on the part of workmen who left a detonator lying about caused injury to the man who found it. A foreman was injured by treading on fulminate spilt by workman, who failed to warn him. An attempt to remov the contents of a cap with a pointed object, caused sligh injuries to a girl. Several explosions due, among othe causes, to carelessness, such as attempting to remov caked composition with a wire brush, occurred in th manufacture of toy caps (amorces), and the effect in on case was aggravated by the presence in the workroom o excessive quantities of the article. An explosion of re phosphorus and chlorate was due to ignorance of th sensitiveness of such mixtures, and the absence of prope moistening. Numerous minor injuries to the face b burning occurred at firework factories.—O E. M.

Government Laboratory. Report of Principal Chemi for year ended March 31st, 1914. See XXIII.

Patents.

[Nitro] derivatives of toluene; Manufacture of — A. E. Vergé, Vincennes, France. Eng. Pat. 17,12 July 25, 1913. Under Int. Conv., May 31, 1913.

The "liquid trinitrotoluenes," used in the manufacture gelatinous explosives, are of variable composition ar always contain certain amounts of mononitrotoluen which evaporate gradually from the mixture, causing t solid nitro compounds to crystallise, with the result th the explosives gradually harden. This invention relates to the production of mixtures of nitrotoluenes which are true liquids, *i.e.*, no solid separates on cooling until the whole mass of liquid freezes, and which contain no mononitrotoluenes. To obtain such products, it is necessary to use as raw material a mixture of mononitrotoluenes containing between 45 and 85% of the *m*-nitro compound. When mixtures beyond these limits are used, only solid or pasty products are obtained. Liquid mixtures of dinitrotoluenes may be obtained by nitrating uch mixtures of mononitrotoluenes with sulphuric acid-nitric acid mixtures in the usual way, or by mixing in uitable proportions the dinitro compound obtained from *m*-nitrotoluene with the dinitro-compounds from *o*- and *p*-nitrotoluenes. "Super-nitrated" liquids are obtained by dissolving suitable amounts of pure or commercial olid trinitrotoluene (m.pt. 82° C. or 70°—72° C.) in the iquid mixtures of dinitro compounds; by nitrating in he usual manner the liquid dinitro compounds and dissolvng certain quantities of these trinitro compounds in the iquid dinitro compounds; by nitrating a mixture of olid trinitrotoluene with *m*-nitrotoluene containing the ecessary proportions of the *o*- and *p*-nitrotoluenes; by nitrating the mixture of mononitrotoluenes in such a anner as to produce directly the desired amount of rinitrotoluenes. This last method is not recommended, as t requires a higher temperature, and always entails a oss of the product by oxidation. By these methods it is ossible to obtain a series of liquids containing up to 16% itrogen, which show no appreciable loss or change after eating to 60° C. for 24 hours.—T. F. B.

xplosives. A. E. Charbonneaux, San Francisco, U.S.A. Eng. Pat. 6608, March 16, 1914.

EE U.S. Pat. 1,093,767 of 1914; this J., 1914, 569.—T.F.B.

xplosive priming composition. A. Jaques, Redding, and G. Wells, St. Albans, Assignors to Nobel's Explosives Co., Ltd., Glasgow. U.S. Pat. 1,106,147, Aug. 4, 1914. Date of appl., Oct. 4, 1913.

EE Eng. Pat. 23,450 of 1912; this J., 1913, 674.—T. F. B.

XXIII.—ANALYTICAL PROCESSES.

opper; Iodate method for determination of ——. W. W. Brostrom. Eng. and Min. J., 1914, **98**, 215—216.

HE copper is reduced with sodium sulphite solution in he presence of hydrochloric acid, and precipitated with otassium thiocyanate. The precipitate is washed, decomosed with hydrochloric acid in the presence of a little arbon tetrachloride and the solution titrated with potasium iodate, until the red colour produced at first is disharged. An accurate determination of copper in ore can e made in 40 mins. Results obtained by different hemists and by three different methods are given, showing he accuracy of the iodate method.—A. T. L.

ead; Sensitiveness of some reagents for ——. E. Eegriwe. Z. anal. Chem., 1914, **53**, 420—426.

EUTRAL aqueous solutions of lead nitrate of successively ecreasing concentration were treated under standard nditions with the reagents, the best quantities of hich were determined. The results for 16 reagents are corded in a table. Potassium bichromate (1 grm. Pb in 100,000 c.c.) and sodium sulphide (1 grm. Pb in 2,840,000 hen the test liquid was compared with its own volume f water containing the reagent) showed the highest nsitiveness. Usually very small quantities of reagent ere best, but in the case of hydrochloric acid, potassium dide, and sulphuric acid the use of comparatively large uantities, by suppressing the ionisation of the lead salt rmed, increased the sensitiveness.—O. E. M.

eroxydase reaction; The sensitiveness of the —— A. Bach. Ber., 1914, **47**, 2122—2124.

HE peroxydase was obtained free from impurities by ubmitting the juice from horse-radish to ultrafiltration rough a collodion film. The solution was used directly after determining its content of solid matter by evaporation. Tested by oxidation of pyrogallol the new preparation gave 98 mgrms. of purpurogallin per mgrm. of enzyme against 36 mgrms. from a preparation by Bach and Tscherniack's method (basic lead acetate and dialysis; see this J., 1908, 823) and 2 mgrms. from a preparation by Bach and Chodat's original method (this J., 1903, 384). An improved method for testing the sensitiveness of peroxydases makes use of guaiacol and hydrogen peroxide. This reagent shows the extraordinary sensitiveness of peroxydase, a solution of 1 part of enzyme in 1,000,000,000, giving a brown-red coloration after 20 mins. and a solution of 1 : 2 billions giving a reaction after standing for 24 hours.—J. B.

Antimony; Detection of —— in qualitative inorganic analysis. J. Petersen. Z. anorg. Chem., 1914, **88**, 108.

The sulphide precipitate, containing possibly arsenic, antimony, and tin, obtained in the course of qualitative analysis, is treated with sodium peroxide, in the presence of a little water, the mixture heated to boiling, and any precipitated stannic acid filtered off. Antimony is indicated by a separation of sodium metantimoniate on cooling. Arsenic may be detected in the same solution by adding concentrated hydrochloric acid and then Bettendorff's reagent (stannous chloride in fuming hydrochloric acid).
—F. Sodn.

Mercuric chloride; Volumetric determination of ——. W. Stüwe. Chem.-Zeit., 1914, **38**, 320.

10 c.c. of 2% mercuric chloride solution are placed in a 100 c.c. measuring flask and 10 or 15 c.c. of 1% hydrazine sulphate solution added. A small amount of sodium bicarbonate is added and the flask warmed slightly and shaken for 15 mins. The liquid is made up to the mark after cooling and 50 c.c. filtered from the reduced mercury into a 300 c.c. stoppered bottle. After acidifying with acetic acid and the addition of some sodium acetate, excess of $N/10$ iodine is added and titrated back with $N/10$ thiosulphate after another 15 mins. standing. 1 c.c. of $N/10$ iodine corresponds to 0·013576 grm. of mercuric chloride.
—F. Sodn.

Iodine in organic compounds; Determination of ——. F. Eckardt. Pharm. Zeit., 1911, **44**, 441. Pharm. J., 1914, **93**, 223.

To determine the iodine in iodo-albumins, a weighed quantity of the substance is moistened in a platinum crucible with sodium hydroxide solution. The mixture is heated until dry and finally until completely charred. The carbonised residue is then extracted with water and sufficient tartaric acid added to give a weak acid reaction. The liquid, without filtering from particles of carbon, is treated with sulphuric acid and sodium nitrite and the iodine thus set free is extracted by shaking out with carbon bisulphide. It is then placed in a flask with water and titrated with sodium thiosulphate solution.

Citric acid; Colour reaction of ——. E. P. Häussler. Chem.-Zeit., 1914, **38**, 937.

The solution is evaporated to dryness after the addition of an alcoholic solution of vanillin, and the residue treated with 3 drops of dilute sulphuric acid, heated on a water-bath for 15 mins., dissolved in water, and ammonia added. A bright red coloration is obtained with 0·002 grm. of citric acid. This red coloration is not given, under similar conditions, by tartaric, malic, oxalic, malonic, benzoic, salicylic, acetic, lactic, succinic, and teresantalic acids, and the presence of these acids does not interfere with the reaction given by citric acid. To detect citric acid in raspberry syrup, 50 c.c. are neutralised, 50 c.c. of water and 75 c.c. of alcohol are added, and the organic acids, etc., precipitated with lead acetate. The lead precipitate is decomposed with hydrogen sulphide, the solution evaporated, the syrupy residue extracted with alcohol, and the alcoholic solution evaporated with the addition of calcium carbonate. The calcium salts are collected, washed with alcohol, and tested as described.
—W. P. S.

Government Laboratory; Report of the Principal Chemist of the —— on the work of the Laboratory for the year ended March 31, 1914. [Cd. 7562.]

The total number of samples examined in the two branches of the Government Laboratory during the year was 234,754, against 209,502 for the preceding year, and 157,613 samples were examined at the Chemical Stations in the provinces.

Beer, brewing materials, cider and perry. Ninety-one samples of beer were examined for saccharin, saponin, and other prohibited substances, but excepting in two samples which contained saponin, no deleterious or illegal substance was found. Of 511 samples of herb beer and other temperance beverages, 401 did not contain more than the legal limit of 2% of proof spirit, 74 contained 2—3%, 31 contained 3—5% and 5 contained 5—7%. Of 1596 samples of beer and brewing materials, only 7 contained arsenic in excess of the limits laid down by the Royal Commission on Arsenical Poisoning; none of the 306 samples of malt and sugar tested contained arsenic, and only one of the 1143 samples of wort and beer tested contained arsenic in excess of the limit, the amount in this case being one-thirty-sixth of a grain per gall.; of 147 miscellaneous samples, 6 contained excess of arsenic, the highest amount being one-eighth of a grain per gall.; the substances in which the arsenic exceeded the limit were not allowed to be used in brewing. Of 15 samples described as cider, 12 were found to contain no apple juice; of 286 samples of imported cider, one was factitious and was assessed for duty on the basis of the spirit which it contained, and another proved to be liable to duty as "wine."

Spirits. Of 40 samples of fusel oil from distilleries in this country, 2 contained more than the permitted proportion (15%) of proof spirit, and of 124 samples of imported fusel oil, none exceeded the 15% limit. Of 3884 samples of exported liniments, hair washes, and other spirituous preparations, 2 liniments were found to have been made from methylated spirit, but this was due to carelessness on the part of the exporters' employees and not to a deliberate illegal use of denatured spirit. Of 39,700 samples of imported spirits and spirituous preparations, one sample, described as "Molasses," was found to contain 29·1% of proof spirit, and 15, entered as wood naphtha or crude methyl alcohol, consisted of methyl alcohol so purified as to be liable to spirit duty. Of 961 samples of wood naphtha submitted for approval in the preparation of methylated spirit, 7 were rejected as unsuitable; all the samples of mineral naphtha—224 in number—for use in conjunction with wood naphtha for denaturing, were approved. The marked reduction, referred to in the last Report, in the quantity of petroleum ether used in admixture with methylated spirit in the manufacture of felt hats has continued, only 32 samples, representing 2901 galls., being submitted as against 57 samples representing 3245 galls., in the preceding year. For controlling the use of methylated spirit in connection with manufacturing operations where the use of stills is permitted, 57 samples of preparations made with methylated spirit, and 37 samples of industrial methylated spirit, "finish," and methyl alcohol, were received for examination. Forty-one samples of mineralised methylated spirit were analysed in connection with the unlicensed sale of this article, or with the illegal substitution of industrial methylated spirit for the mineralised variety.

Sugar, glucose, saccharin. The number of samples of sugar and articles containing sugar examined for assessment of duty or drawback was 42,644. Owing to the heavy duty on saccharin, the presence of this substance has to be searched for in all preparations likely to contain it; of 304 samples tested, mainly consisting of condiments, dentifrices, and medicinal preparations, 105 contained saccharin.

Matches. Of 1333 samples examined, none was found to contain white phosphorus.

Imported dairy products. The following numbers of samples were examined: Milk, 12; condensed milk (sweetened, unsweetened, and powder), 172; cream, 98; butter, 1258; margarine, 716; cheese, 72. All the samples of fresh and sterilised milk were free from preservatives, but one sample of sterilised milk was slightly deficient in non-fatty solids. Of the butters, 355 samples contained boron preservative and 148 contained added colouring matter. None of the samples of margarine contained more butter fat than is legally permissible (10%) but 22 contained water in excess of the legal limit of 16%. All the samples of margarine were free from paraffin wax, a substance occasionally present in cheap margarine.

Apples. Apples with a slight deposit on the skin near the stem and near the "eye" were found to contain a trace of copper equal to three-hundredths of a grain per lb., due probably to spraying with Bordeaux Mixture. The amount of copper found in the apples was not greater than has been found to occur naturally in wheat, potatoes and beans.

Lead glazes and leadless glazes. The samples of leadless glaze examined were generally found to comply with the Home Office requirement according to which the glaze must not contain more than 1% of lead monoxide. Numerous samples of glazes, avowedly containing lead, were examined for total lead-content, and for the amount soluble in hydrochloric acid of the concentration present in gastric juice. In 51 cases where lead poisoning had occurred, it was found that almost all the lead was soluble in the dilute acid. In one case, the glaze contained 70% of lead monoxide of which practically the whole was soluble.

Board of Trade. Experiments on the suitability, from a hygienic point of view, of galvanised iron vessels as milk measures, showed that fresh milk dissolved no zinc or only traces in 2 hours. When, however, milk was allowed to go sour in the vessel, appreciable quantities of zinc were dissolved. At the end of 24 hours, the milk contained zinc equal to about half a grain per pint. Traces of arsenic and antimony, present as impurities in the zinc coating of the vessel, were also found in the milk which had been kept for 24 hours in the vessel, the amount of arsenic in one case being one-hundredth of a grain per gall.

Sale of Food and Drugs Acts. Seventy-three samples were referred by magistrates under the provisions of these Acts, viz., milk, 52; whiskey, 4; jam, 3; butter, 2; pepper, 2; rum, 2; and margarine, almond oil, coffee, dripping, gin, lard, jelly and vinegar (1 sample of each). The results of the examination at the Government Laboratory differed from those of the public analyst in 8 cases out of 65.

Fertilisers and Feeding Stuffs Acts. Twenty-four samples, comprising 9 fertilisers and 15 feeding stuffs, were submitted by the Board of Agriculture and Fisheries in connection with applications for consent to take proceedings against the sellers. The nitrate of soda examined contained a considerable amount of perchlorate, and the other fertilisers were deficient in phosphates, nitrogen, or potash. Several of the feeding meals were deficient in oil or albuminoids.—L. E.

National Physical Laboratory. Report for the year 1913—1914.

In order to allow of changing the financial year of the Laboratory so that it will end on March 31st, the present report covers a period of 15 months, viz., from Jan. 31, 1913, to March 31, 1914.

Standard cells. The slow steady fall of electromotive force which occurs in many Weston normal cells is probably due to hydrolysis of mercurous sulphate, a solution of hydrolysed mercurous sulphate having a lower concentration of mercury ions than one in contact with non-hydrolysed salt. If the hydrolysed and non-hydrolysed salts are in contact with a solvent and with mercury, the latter acts as an electrolytic catalyser, accelerating a reaction which tends to diminish the concentration of mercury ions in the layer of liquid in contact with the mercury. Displacement of the contact layer by agitation or by convection currents due to rise of temperature, produces an increase of e.m.f., as the replacing liquid is richer in mercury ions. The hydrolysis of mercurous sulphate can be prevented by adding 1 part of sulphuric acid per 10,000 parts of water.

Resistivity of steel conductor rails. The usual practice o specifying the resistance of steel rails in terms of copper is deprecated; the results differ according to whether th comparison is made between copper and steel of the sam length and weight or of the same length and sectiona area. The resistance should be expressed in ohms or microhms, and the rail defined in terms of the weight in b. per yard as is customary in commerce. The resistance expressed in different ways), temperature coefficient, and composition of electrolytic iron (No. 1), a piece of ordinary running rail (No. 6), and four samples of conductor rails (Nos. 2, 3, 4 and 5) are given in the following able :—

Sample.	Microhms per 100 lb. yard.	Relative resistivity.		Temp. coeff. % for 1° C.	Percentage composition.								
		Mass.	Volume.		C.	Si.	S.	P.	Mn.	As.	Cu.	Ni.	Cr.

Thermometer glasses. Using thermometers specially made about 11 years ago and which had never been raised above room temperature, the thermometric behaviour of the four glasses, Jena 16^{III}, Jena 59^{III}, *Verre dur*, and Kew glass was studied. The values found for the emporary depression of the zero corresponding to 30°, 60°, 75°, 100°, and then at every 50° C. up to the temperature of anneal were smaller than almost all of the orresponding values published by other investigators. n regard to the secular rise of the zero over a long period of years, the rate of change was found to be very small, he greater part of the change occurring within a few months of the anneal. The *Verre dur* was found to contain rom 2 to over 6% Pb. One of the *Verre dur* thermometers was a standard certified by the Bureau International, nd it is pointed out that the International Scale of Temperature was originally interpreted on a scale employing *Verre dur* free from lead.

Sikes' hydrometers. Accurate comparison of metal ydrometers in alcohol solutions of specific gravity pproaching that of water is very difficult, as such solutions o not wet the stems properly, but concordant results an be obtained with instruments of the same size by dding a small quantity of a dilute solution of sodium arbonate, the density being brought to the original alue by addition of a little more alcohol. In comparing instruments of different sizes or a metal instrument with glass one, this method cannot be used owing to the isturbing effect of surface tension, and in such cases large number of readings must be taken under varying conditions, and the mean value calculated. The stems f metal instruments must be kept scrupulously clean. nd the hydrometers are therefore kept immersed in lcohol.

Mercurial barometers. The baromil scale has been dopted by the Meteorological Office. A "baromil" is efined as the height of a mercury column which, at 0° C. n latitude 45°, at sea level, produces a pressure of 1 millibar (1 kilodyne or 1000 dynes per sq. cm.). 1 baromil =0·0295306 inch=0·750076 mm. Barometric inch scales re graduated to be standard at 62° F. and millimetre nd baromil scales to be standard at 0° C., and the following conversion factors must be used to express the relations etween the actual lengths at any common temperature f inch scales standard at 62° F., and mm. or baromil cales standard at 0° C., all being graduated on International brass (coefficient of expansion=0·0000184 per C.): 1 in.=25·3922 mm.=33·8528 baromils ; 1 mm.= ·0393822 in.=1·33320 baromil ; 1 baromil=0·0295396 in. =0·750076 mm.

Radium. The British Radium Standard consisting of 1·1 mgrms. of radium chloride, purified and standardised y Prof. S. Meyer, of Vienna, and compared directly with he International Standard, at Paris, by Mme. Curie, as been in use since the middle of December last, and early £3000 worth of radium in the form of relatively ure preparations of radium and mesothorium, have een tested. The samples must be enclosed in a sealed tube for 5 or 6 weeks before testing. The γ-ray activity will then have reached a practical maximum and the intensity of the penetrating γ-rays which are emitted serves as a measure of the radium content. Three different methods are used :—(1) a combined gold-leaf electroscope and ionisation chamber ; (2) Rutherford and Chadwick's method, in which the ionisation produced by the sample is balanced against a steady source of ionisation (viz., a film of uranium oxide prepared by McCoy's method of deposition), and the distance from the ionisation chamber observed both for the standard and the sample being tested : for distances above 50 cm. the inverse-square law holds with considerable accuracy ; (3) an apparatus modelled on one designed by Mme. Curie, in which an aluminium plate, 60 cm. diam., is interposed between two thick lead plates of the same diameter, adjoining plates being separated by an air-gap of 2 mm. : the sample is placed on the centre of the upper plate, and the aluminium plate is insulated and connected with an electrometer ; the two outer plates are then put in metallic contact and charged to a high potential, and the γ-ray ionisation measured in the air-gaps between the plates. All results are expressed in terms of radium metal.

Balloon fabrics. Comparative tests in which samples were "weathered" for some months on the roof, showed the greater value of "metallising" as compared with coating with yellow pigments for protecting rubbered fabrics.—A. S.

Pyrometer; Optical ——. Siemens und Halske Akt.-Ges. Fr. Pat. 466,063, Dec. 11, 1913. Under Int. Conv., Aug. 4, 1913.

The pyrometer is of the kind in which an electric incandescence lamp of known candle-power is mounted within a telescope containing a photometric screen, and a test is made by securing an equal illumination of the screen by the incandescence lamp and by the source of light tested. The fittings on the telescope tube for the electric lamp and for its leads are arranged so that the telescope will normally be held in such a position that the lamp filament is vertical. In order to ensure constancy in the illuminating power of the lamp, a second lamp having a filament with a different temperature-coefficient is arranged in series with it and with a regulating resistance. This second lamp is arranged in a branch tube of the telescope so that different parts of the screen can be illuminated by the two lamps, and the resistance is adjusted until the illumination from both lamps is the same, which can only occur with one particular current. The second lamp is then withdrawn sufficiently for its light to be entirely cut off from the screen and the photometric test is made by moving a wedge of dark glass, or by adjusting a set of dark glasses between the tested source of light and the telescope.—A. T. L.

Calorimeter for gas and other fuels. C. Féry. Fr. Pat. 467,180, Jan. 10, 1914.

A rose-burner for gases, or a wick burner for liquid fuels, is arranged within a lamp-chimney into which air is drawn by the natural draught through a tube provided with a device sensitive to the velocity of the air current. This device indicates the calorific power on a scale, or records it on a drum, the instrument being calibrated by means of a gas of known calorific power. If the fuel is not burned at the standard rate, the rate of fuel consumption is also determined. The device sensitive to the velocity of the draught may be a wheel with inclined vanes suspended by a torsion thread, or a horizontal disc carried on one end of a balanced lever and displaced vertically by the current of air.—A. T. L.

XXIV.—MISCELLANEOUS ABSTRACTS.

Tobacco; Studies in the curing of leaf ——. W. W. Garner, C. W. Bacon, and C. L. Foubert. Bull. 79, U.S. Dept. Agric., April 13, 1914. 40 pp.

The investigation, mainly a comparison of curing on the stalk with curing of the picked leaf, refers to Connecticut cigar wrapper leaf. The curing of picked leaf is due chiefly to respiration, while curing on the stalk is accompanied by a considerable transference into the stalk of nitrogen compounds from the protein, mineral constituents, nitrate, and carbohydrates. The loss of dry material from the leaf is correspondingly about twice as great as the 12 to 15% loss from picked leaves. It is reduced when the stalks are split, as in the case of manufacturing types, the loss from which, and from cigar-filling types, reaches 40%, even with picked leaves. Thorough air curing, by the action of diastatic, proteolytic, and deamidising enzymes, and probably oxidases, causes a disappearance of starch and reducing sugar, a decrease of pentosans, malic acid, proteins, nicotine, and total nitrogen, and an increase in citric acid. The rate of curing is rapidly increased by rise of temperature up to the point at which the protoplasm is killed, viz., about 130° F. (54·4° C.). The moderate use of artificial heat does not affect the composition of the product. Thorough wilting early in the process promotes the curing if the further drying of the leaf is not too rapid.—O. E. M.

Factories and Workshops; Annual Report of the Chief Inspector of —— *for the year* 1913. pp. vi+191. [Cd. 7491.] Price 1s. 7d.

Dust explosions. Nine carbonaceous dust explosions were reported in the United Kingdom during the year, as compared with seven during 1912; they include coal 2, shoddy 2, dextrin, starch, and flour 1, malt 1, cork 1, distillery meal 1, and copal gum 1 That at a gum and starch factory was serious, causing 3 fatalities and wrecking a seven-floored building; it was due to dust from a beam falling on a naked light (compare Report for 1911; this J., 1912, 698). An inquiry into a violent explosion of paper dust brought about by the use of lanterns during the cleaning of a dust chamber at a paper tube works in France confirms the view expressed in a previous Report, that the use of a stive room in connection with grinding and cleaning machinery is unnecessary and should give place to more modern methods of intercepting dust, such as the cyclone collector or bag filter. The testing of carbonaceous dusts by R. V. Wheeler (this J., 1913, 447) has been extended; "syrolit," a composition of milk curd and formaldehyde, used as a substitute for celluloid, showed a relative ignition temperature of 1050° C. and was placed in Class I. as a dangerous dust; distillery meal dust, with relative and lowest ignition temperatures 970° and 640° C. respectively, was also placed in Class I.; and dust of myrabolans and valonia nuts from a tannery, giving no ignition up to 1400° C. in the relative test, and lowest ignition temperature 660° C., was placed in Class II. as inflammable but not dangerous. Three explosions in the crank chambers of high speed engines were caused by the ignition of fine spray produced by action of the cranks on oil which had a flash point of 400°—450° F. (204°—232° C.).

Industrial poisoning. The number of cases of poisoning and the fatalities (in brackets) notified during 1913 and 1912 respectively were: lead 535 (27), 587 (44); arsenic 6, 5; mercury 14, 17; anthrax 70 (7), 47 (6). The total for lead poisoning compares favourably with that for any preceding year except 1910, although an increase in the number of deaths has been noted since 1906; the latter is, however, considered due to a greater inclination on the part of medical practitioners, since the application of the Workmen's Compensation Act, 1906, to associate the occupation with the chronic nephritis and cardiac failure so frequently appearing on the death certificates of lead workers A serious outbreak of poisoning in the *heading of yarn*, dyed with lead chromate, led to analyses of the fluff and dust from beams in the work rooms. These showed amounts of lead varying from 3·1% (calculated as oxide) in rooms where chrome green yarns, containing only 3·7% of lead, were headed, to 22·2% in those where lead-dyed yarns were picked. All the samples were practically free from arsenic, but antimony (0·31%, calculated as oxide), probably used as a mordant and present as a tannate in the finished yarn, was found in royal blue and (0·23%) in aniline green yarns, and the symptoms were such as to suggest the combined toxic action of lead and antimony. Improved exhaust draught and remodelling of the dust-collecting orifices has led to improvement in the health of the workers. Some cases of lead poisoning reported involved very little exposure to lead, *e.g.*, scraping labels off cans and occasionally painting them, handling pipes covered with dry paint, or working brass containing a small percentage of lead. Other cases occurred in the burning of old ship plates coated with red lead, the fixing of iife handles by means of lead, and the testing of springs mpered in molten lead. Cases of plumbism in chandelier ters have diminished in consequence of "caulkite" ving largely ousted white lead as a jointing material, d the use of the air pump and pressure gauge replaced e testing of fittings by mouth suction; and lessened verity of symptoms, with fewer cases, are reported in the llow ware industry, as a consequence of the Tinning gulations. The use of leadless paint is extending, and k of poisoning in the repairing of old paint drums has en reduced by boiling them in a bath of sodium sulphate. ie following table shows the attack-rate from lead poison- g in certain industries for 1913 and 1912.

Industry.	Approximate number employed in lead processes.	Attack-rate per thousand	
	1913.	1912.	1913.
ute lead	1201	17	24
reous enamelling	933	5	10
ning of metals	878	17	10
etric accumulators	1475	30	30
nts and colours	1400	13	16
thenware and china	7085	13	9
elting of metals	2878	23	9
ch painting	29,308	3	2
cutting	5556	2	3
ating	58,777	0·6	0·4

)f the six cases reported under *arsenic poisoning*, two urred in the manufacture of sheep dip, one in the raction of arsenic, and one in bronzing. A case of lrogen arsenide poisoning was caused by dissolving containing 0·08% of arsenic (calculated as oxide) in lrochloric acid containing 0·14% of arsenic (compare milar case in Report for 1912; this J., 1913, 764), and ther case at a shale oil works in Scotland has been traced gases generated by the action of acid residues from a turator" on a new galvanised iron pail.

Iercurial poisoning was reported in connection with the nipulation of mercury fulminate (4 cases), the manufac- e of mercury compounds (3), felt hats (3), and ther- meters and barometers (2), and the making of electrical ters (1) and mercury vapour lamps (1). Cases of *hrax* reached a higher figure than in any previous r owing to an increased number contracted from wool. inquiry by the Anthrax Investigation Board showed that t, applied by steaming or otherwise, is impracticable as isinfecting agent for wool, from the bale, except of such od-stained material as is removed in preliminary sorting, account of the expense and damage to the colour, lustre, ngth, and elasticity of the fibres, but the proved disin- ion of blood-stained material is regarded as an important). Reference is made to the work of Hilgermann and rmann and of Abt (this J., 1913, 1078) on the relative its of the Seymour-Jones formic-mercury process s J., 1912, 35) and the Schattenfroh hydrochloric acid salt method (this J., 1911, 1127) for disinfection of s and skins infected with anthrax. The latter seems more reliable for sterilising contaminated hides, Abt prefers the Seymour-Jones process for disin- ing large batches of skins as a preventive measure. rt from disinfection, the formic-mercury process ears to have remarkable properties in bringing dry s into a soft and supple state.

ttention is drawn to the frequent reports of the value xygen in restoring the unconscious after gassing, but hasis is laid on the danger of working alone or in fined spaces where there is a risk of gas poisoning.) of the cases under *benzene and naphtha* occurred to painters working in confined spaces, one (fatal) was to "flushing" (*i.e.*, an uncontrolled rush of vapour ing distillation), and another (also fatal) occurred to a employed in dry cleaning. Two cases are reported in manufacture of dinitrotoluene and trinitrotoluene and cases of toxic amblyopia from the use of dinitro- zene at an explosives works; but at a large works in the Huddersfield district manufacturing nitro- and amino-derivatives of benzene, cases of poisoning have been reduced from 20 in 1911 to 1 in 1913, owing largely to the adoption of more efficient systems of exhaust ventilation and better observance of the Regulations by the workers. A case of slight poisoning by nickel carbonyl is also reported, the symptoms being moderate cyanosis. The dipping of metal in acids, carried on in the Birmingham and Coventry districts, has been noticed to have a very marked corrosive effect on the teeth, and there was evidence of bronchial trouble (a well-known result of inhaling nitrous fumes, leading to death within a short period if the symptoms become severe).

Accidents due to *fumes and gases* during 1913 and 1912 are given in the following table, with fatalities in brackets.

	1913.	1912.
Carbon monoxide	59 (7)	91 (13)
Carbon dioxide	12 (1)	3 (2)
Hydrogen sulphide	8 (1)	6
Sulphur dioxide	1	5
Chlorine and hydrochloric acid	1	3
Nitrous fumes	nil	12 (1)
Ammonia	3	1
Benzene and naphtha	6 (2)	3 (1)
Nitro- and amino-derivatives of benzene	2	9 (1)
Other	2	2 (1)

Pitch ulceration. The draft Regulations dealing with the manufacture of patent fuel, with addition of pitch, have been withdrawn upon agreement with the manufacturers as to the provision of extra lavatory, bath, and cloak room accommodation and the further encasement of elevators. In one works a method of treating tar with formaldehyde is being tested; this, it is alleged, eliminates the auxetic elements in the tar, so as to produce pitch having less effect on the skin than ordinary pitch. The number of cases of pitch warts or of epitheliomatous cancer, the result of them, was 19, and 2 cases of serious skin affections in creosoting factories are also reported. There were a few cases of *paraffin cancer*, a disease to which shale oil workers are peculiarly liable The shale is heated in vertical retorts and the resulting crude oil distilled by heating and blowing steam through it; the "green oil" thus obtained is treated with 2% sulphuric acid and 1% caustic soda and is then again distilled with steam and fractionated, giving 'light oil," "intermediate," and "heavy oils." The light oil, after treatment with acid and alkali, gives upon distillation "burning oil," ready for use, and more of the intermediate oil. The heavy oil is cooled, pumped through ammonia freezers and filter-presses, washed with acid and alkali, and again distilled, yielding intermediate oil and "lubricating oil." All the intermediate and lubricating oil is passed through coolers, freezers, and filter-presses, and the residual "scale," which causes the eruption on the arms of the workers, is pressed, purified by slow heating, treated with animal black, and finally converted into wax. Rubbing the hands and arms after washing with a solution of carbolic acid and glycerin has been found to lessen the irritation produced by the scale. The Glasgow inspector reports that at a factory where crude paraffin wax was refined, the workers suffered from large boils, but personal cleanliness was said to be a certain preventative. The addition of a small amount of a disinfecting fluid (creosote or carbolic acid) to mineral oils used as lubricants (particularly shale oils) has been found effective in preventing eczema in engineering factories. During the year, the Special Rules of 1900 for the manufacture of chromate and bichromate of potassium and sodium, introduced in consequence of *chrome ulceration* among the workers, have been replaced by Regulations (this J., 1913, 750). In the Scotch works the effect of chrome dust on the nasal septum has been evident, despite elaborate exhaust ventilation at packing, and perforation sooner or later is said to be the rule. It is questionable whether the bichromate is the actual poison which causes the ulcers or whether their formation is not rather due to microbic attack supervening on the action of bichromate, which by preventing healing, prepares the way for microbic infection. Promising results as a preventative in chrome tanning have been obtained with a disinfecting ointment made from mineral lard 3 lb., paraffin wax 6 oz., and "cyllin" 3 oz., to be rubbed into the parts exposed to the liquor before starting work. Poisoning rarely if ever occurs in chrome tanning where the one-bath process (with a solution of chromic salt) is in vogue, but is well known where the two-bath (bichromate and thiosulphate) method is adopted. Cases of chrome ulceration amongst French polishers are also reported, although it is said the trouble can be avoided by applying linseed oil to the hands and arms before work. Inquiries into the prevalence of *salt ulcers* among herring- and gut-curers have shown that common salt, in the dry or wet state, has an effect very similar to bichromate. Frequent washing has proved most beneficial in these cases, and promising trials have been made with the ointment mentioned above.

A study by Collis of the effects of *dust* in producing diseases of the lungs has led to the following conclusions:—(1) Inhalation of all forms of dust is accompanied by diminished power of chest expansion, with correspondingly high blood-pressure. (2) Animal dusts, apart from the presence of pathogenic micro-organisms, produce less effect than vegetable or mineral dusts. (3) Vegetable dusts tend to produce an asthmatic type of chest affection. (4) Mineral dusts which do not contain free silica tend to produce irritation of the upper air-passages and respiratory diseases other than phthisis, those composed of calcium salts being least injurious. (5) Inhalation of mineral dusts which contain free silica is associated with an excess of phthisis; an excess which bears a direct relation to the amount of free silica present. (6) In general, dusts appear to be more injurious as their chemical composition differs from that of the human body, or from the elements of which the body is composed.—F. Soddy.

Trade Report.

Prohibited exports. Order-in-Council, dated Sept. 8th, 1914, supplementing and amending previous lists.

The following are deleted from the list of articles included in His Majesty's Proclamations, dated August 5th and 10th, 1914 (see this J., 1914, 810):—

Tin, tungsten, nitro-toluol, castor oil, boric acid, digitalis and its preparations, all fine chemicals.

The heading "Manganese" should read "Manganese, including ferro-manganese."

The exportation of iron ore, raw rubber, and castor oil, is prohibited to all foreign ports in Europe and on the Mediterranean and Black Seas other than those of Russia (except Baltic Ports), Belgium, France, Spain and Portugal.

The following are added to the list of prohibitions to all destinations contained in former proclamations:—Tungsten, wolfram ore, nitro-toluol, acetanilide, acetylsalicylic acid (aspirin) and salicin, aconite and its preparations and alkaloids, adrenin (adrenalin) and its preparations, ammonium sulphocyanide, antipyrine (phenazone), balsam of Peru, benzoic acid (synthetic) and benzoates, cantharides and its preparations, chloral and its preparations, including chloramid, chrysarobin, citrate of magnesia, citric acid, alkaline citrates and calcium citrate, coal tar products for use in dye manufacture, diethylbarbituric acid (veronal) and veronal sodium, dulcite, dyes and dyestuffs obtained from coal tar, emetin hydrochloride, eucaine hydrochloride, ergot of rye and its preparations and alkaloids, gentian and its preparations, glacial acetic acid, hexamethylene tetramine (urotropin) and its preparations, hydrobromic acid, hydroquinone, mannite, neo-salvarsan, novocain, oil of turpentine, paraldehyde, paraffin (liquid, medicinal), pastilles, jujubes, lozenges and cachous generally containing prohibited ingredients, "peptone Witte," phenacetin, pilocarpine salts, potassium and its salts and preparations (including bichromate and prussiate of potash), pyrogallic acid, saccharin (including "saxin"), santonin and its preparations, sulphonal, sulphate of zinc, tartaric acid and alkaline tartrates, thymol and its preparations, trional.

Competition with Germany and Austria-Hungary. List of articles in connection with which applications have been made to the Board of Trade with a view to getting into touch with buyers or sellers. August, 1914.

Firms who can supply any of the articles asked for or who may wish to buy any of the articles offered below should communicate with the Director of the Commercial Intelligence Branch, Board of Trade, 73, Basinghall Street, London, E.C.

A. *Articles which inquirers wish to buy*:—Acetic acid; aluminium discs, powder, rods, foil, and sheets; aluminium nitrate; asbestos fibre jointing; beryllium nitrate; black lead; brassware, general; bronze powder; carbons for lamps; celluloid, various; ceresine; chemicals, general, and for cleaning and glassworks; china and earthenware; cloth and fibre for incandescent mantles; cork; cotton, mercerised; dextrin and dextrose; drugs; dyes, general, aniline, and naphthylamine black; enamel ingredients, enamel ware; formaldehyde; fuller's earth, prepared for oil filtration; gelatine, tubes; glass and glassware, heat resisting, lamp glass, Jena glass; glass wool, gold foil; graphite, powdered and cake; hydrofluori acid; lighters, automatic; magnalium sulphate; magnesia (oxide); magnesium chloride and nitrate; magnesite manganese sulphate; mantles, incandescent, and magnesi rings therefor; mercury iodide; metals, various; meta foil; methyl chloride; oils, essential; ores and minerals general; paints; paper (impregnated discs and rolls) pearl ash; perfumes; potash, caustic, carbonate, prussiate nitrate, and sulphate; potassium cyanide and iodide rubber (thin gutta percha); silica; silk, artificial silver foil; soap, castile and olive oil; soapstone; soda ash, caustic, carbonate, bicarbonate, and hyposulphite mono-sodium sulphite; starch; sugar; tartaric aci and tartrates; thorium nitrate; tinned hollow-ware vulcanite (mouldings, rods, and sheets); wire, barbe enamelled copper, mild steel, soft basic; zinc, ores, shee oxide, carbonate, and sulphate.

B. *Articles which inquirers desire to sell*:—Acetic acid acetone; acetyl-cellulose; anticorrosives; bleaching powd (chloride of lime); butyl alcohol; capsules (metal calcium sulphate; charcoal powder; chemicals, genera china and earthenware; chrome liquor; cochinea colours; cosmetics; dextrines (white and yellow disinfectants; drugs and veterinary medicines; dye aniline and vegetable; electroplating materials; ename ware; esparto grass; firebricks and fireclay good gelatin; glass and glassware; graduated apparatu glues and gums; gypsum; iron liquor; kaolin; kieselgu and bricks; lampblack; lead, white and red; lithopon machinery for bleaching; mantles, incandescent; manure oils and greases; oxyacetylene welding plant; paint paper; plating; polishes; rubber, synthetic; sod caustic, bicarbonate, washing; tungsten ores; va nishes; vitreosil; vulcanite.

Competition with Germany and Austria-Hungary neutral markets.

In pursuance of the Board of Trade scheme for assisti British manufacturers and traders to secure trade w British Possessions and Foreign Countries, formerly the hands of their German and Austrian or Hungarian co petitors, bulletins have been issued on hollow glass war hollow-ware, enamelled or tinned; iron and steel wi cotton prints; pottery and earthenware; brass war soaps; products of the colour printing industry; linole and oilcloth; pumps and pumping machinery; paint colours and materials; photographic goods.

Inquiries should be addressed to the Director, Commercial ntelligence Branch, 73, Basinghall Street, London, E.C.

aly : Prohibition of certain exports from ——. Board of Trade J., Aug. 20. 1914.

N Italian Royal Decree, dated August 1st, prohibits he exportation of certain articles, including coal, etroleum, petrol, glycerin, lubricating materials, copper, luminium, lead, silicon, sodium nitrate, sulphuric acid, itric acid, calcium carbide, acetone, sulphuric anhydride, icric acid, sodium carbonate, and medicines and sanitary aterial in general, together with the goods enumerated 1 Article 216 of the Mercantile Marine Code (contraband f war).

aly and Norway : Opportunities for British trade in ——. Board of Trade, Sept. 8, 1914.

'HE British Ambassador at Rome states that the present me would be favourable for a competent Italian commercial traveller or agent to go to Milan and obtain orders for oods hitherto supplied by Germany. Amongst such oods for which there would be a demand are carbons for re lamps, magnesium, silica, bricks, and special types of eel.

His Majesty's Minister at Christiania reports that supplies f medical drugs, which are usually drawn from Germany, re reported to be very low in Norway at present. Representatives of the drug industry who were sent to America ave reported that drugs are very expensive there, and it is onsidered that there is a good opening for British products f this nature in Norway.

ndustrial chemistry ; Some economic aspects of —— B. C. Hesse. J. Ind. Eng. Chem., 1914, 6, 678—682.

s the thirteenth census (1910) of the United States, ie following nine principal divisions are included under hemicals and allied products, viz., paint and varnish ; hemicals ; fertilisers ; explosives ; dyestuffs and extracts ; lphuric, nitric and mixed acids ; wood distillation ot including rosin and turpentine) ; essential oils ; one, carbon and lampblack. Comparison of the data for ese industries with those for the manufacturing industries s a whole shows that per unit of plant, the number of ersons engaged in manufacture is 50% greater in the verage chemical plant than in the average manufacturing lant ; the number of salaried employees is more than times as many ; the number of wage-earners is 34% eater ; the expenses (salaries, wages, materials, iscellaneous) are all greater ; the value of the products roduced is 161% more and the excess of the value of the roduct over that of the raw material is 148% more an in the case of the average manufacturing plant. he amount of capital required for the average chemical lant is however 3·3 times that required for the average anufacturing plant ; hence per unit of capital invested, ie expenses and the number of persons employed, laried or otherwise, are lower in the chemical and allied dustries than in other branches of manufacture. Of ie total value of products in the nine principal divisions chemical industry mentioned above, viz., 425,084,540 ollars, the percentage share of each division was :), paint and varnish, 29·4 ; (2), chemicals, 27·4 ; (3), rtilisers, 24·5 ; (4), explosives, 9·4 ; (5) dyestuffs and tracts, 3·8 ; (6), sulphuric, nitric and mixed acids, 3 ; (7), wood distillation, 2·3 ; (8), essential oils, 0·3 ; bone, carbon, and lampblack, 0·4. The percentage ares of the sub-divisions in each of the principal divisions ere :—

Paint and varnish.	Per cent. of total.
gments	13·6
ints in oil	45·4
rnishes and japans	25·0
llers	2·5
ater paints and kalsomine	1·6
Linseed oil	1·5
Bleached shellac	0·5
All other products	9·8

Chemicals.	Per cent. of total.
Acids	10·1
Sodas	18·1
Potashes	0·7
Alums	2·2
Coal tar products	2·3
Cyanides	1·6
Bleaching material	1·4
Chemical products made by the aid of electricity	15·2
Plastics	6·1
Compressed and liquefied gases	4·2
Fine chemicals	9·3
Chemicals not elsewhere specified	29·1

Fertilisers.	Per cent. of total.
Superphosphates	12·8
Ammoniated fertilisers	9·7
Concentrated phosphate fertilisers	3·5
Complete fertilisers	55·0
Other fertilisers	7·8
Sulphuric acid for sale (as 50° B. acid)	0·9
Other acids for sale	0·6
All other products	9·7

Explosives.	Per cent. of total.
Dynamite	46·6
Permissible explosives	2·2
Nitroglycerin	7·9
Blasting powder	24·9
Gunpowder	4·3
Other explosives	9·7
Materials not elsewhere specified	5·4

Dyestuffs and extracts.	Per cent. of total.
Artificial dyestuffs	21·6
Extracts for dyeing	6·2
Extracts for tanning	40·4
Other tanning materials	1·0
Mordants	0·6
Sizes and finishes	15·0
Ground and chipped woods, etc.	2·2
All other products	9·7

Sulphuric, nitric and mixed acids.	Per cent. of total.
Sulphuric acid	57·0
Nitric acid	5·1
Mixed acid	14·6
All other products	23·5

Wood distillation (not including rosin and turpentine.)	Per cent. of total.
Wood alcohol, crude	16·7
Wood alcohol, refined	29·8
Acetate of lime	20·3
Charcoal	21·0
Turpentine	2·6
All other wood distillation products	3·7
All other products	2·8

Bone, carbon and lampblack.	Per cent. of total.
Bone black	50·0
Carbon black	30·3
Lampblack	20·6

Essential oils.	Per cent. of total.
Peppermint oil	29·8
Black birch oil	5·9
Spearmint oil	4·8
Wintergreen oil	3·9
Other oils	19·3
Witch-hazel extract	23·7
All other products	12·4

Within these nine divisions the United States is, in a large measure, self-sustaining, but metals and metallurgy, production of refined petroleum, and many other large industries (glass, oils, fats and soaps, pottery, starch, sugar, etc.) depending upon chemical reactions and chemical control are not included. If the official German classification be adopted, then of a total foreign trade (U.S.A.) of 4,241,484,592 dollars in 1913, 1,302,274,994 dollars, or 30%, represented products of, or materials used in, chemical industry ; of these 18% (759,193,688 dollars) represented imports and 12% (543,081,306 dollars) represented exports. Some of the larger items were :—

Imports.	Dollars.	*Exports.*	Dollars.
Sugar	204,212,581	Refined petroleum and its products	139,882,905
Hides and skins	117,386,174	Copper as metal	120,605,914
Unmanufactured indiarubber	101,333,158	Beef and hog products	82,890,777
Paper and paper-stock	27,706,697	Leather	42,384,199
Potash compounds	14,408,124	Naval stores	26,471,492
		Fertiliser material	11,400,888
		Cement industry	5,822,107

In regard to the German coal-tar dye industry, this is so dependent upon interlocking chemicals and has reached such a stage of complexity and interdependence that it is difficult of transplantation as a whole, but of the relatively few staple products—products consumed in quantities to be measured by tons—several are manufactured successfully in the United States. Moreover, the chemical and engineering work involved, for example, in the production of a useful illuminating oil or a medicinal preparation from crude petroleum, compares very favourably with that involved in the production of most of the coal-tar dyes, and the petroleum products are of greater economic value. Again, the money value of the inorganic chemical industry exceeds that of the dye industry by at least 15 to 1. As as indication of the importance of accurate analytical control of chemical operations, it is pointed out that the United States exports copper to the value of 120 million dollars per annum and that an error of 1% in the determination of copper would mean a loss of 100,000 dollars per month.—A. S.

Books Received.

HISTORY OF THE INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND (1877—1914).

VOLUME (8¾ by 5¾ ins.), containing 300 pages of subject matter, and an alphabetical index. There are four illustrations. The matter is subdivided and classified as follows :—I. Preface. II. Introduction (Professional organisation generally. The Royal Society, the Chemical Society and other Societies interested in Chemical Science. Progress of education in Chemistry). III. Origin and foundation of the Institute. IV. The title "Chemist." V. History of the Institute (1877—1914). VI. Appendix. VII. Constitution and Management.

DIE FLÜSSIGEN BRENNSTOFFE. IHRE BEDEUTUNG UND BESCHAFFUNG. Sammlung Vieweg. Tagesfragen aus den Gebieten der Naturwissenschaften und der Technik. Heft 7. Von ED. DONATH und A. GRÖGER. Friedr. Vieweg und Sohn. Braunschweig. 1914. Price M. 2.

VOLUME (8⅝ by 5½ ins.), containing 86 pages of subject matter. The contents are classified as follows :—I. Liquid fuels and their advantage. II. Varieties of liquid fuels. (*a*), Petroleum. (*b*), Coal tar and lignite tar production, in the improved methods of utilising those fuels. (*c*), Spirits. (*d*), Fatty oils. III. General conclusions.

A MANUAL OF PRACTICAL PHYSICAL CHEMISTRY. By FRANCIS W. GRAY, M.A., D.Sc., Lecturer. Physical Chemistry Department, Aberdeen University. Macmillan and Co., Ltd., St. Martin's Street, London, 1914.

VOLUME (7½ by 5 ins.), containing 203 pages of subject matter with 61 illustrations, and 18 pages of tabular matter. An alphabetical index closes the work.

ANNUAL REPORT OF THE CHIEF INSPECTOR OF FACTORIES AND WORKSHOPS FOR THE YEAR 1913. [Cd. 7,491.] Wyman and Sons, Fetter Lane, E.C. Price 1s. 7d.

THIS publication contains the general report of the Chief Inspector upon the work of the Factory Department of the Home Office in 1913, as well as statistical tables. A comprehensive report by the Senior Superintending Inspector of factories and the Inspector for dangerous trades is introduced for the first time, and reports are included by the principal lady inspector, and the Electrical and medical inspectors. At the end of the year there were upon the registers 120,062 factories and 154,507 workshops.

PATENTS, DESIGNS, AND TRADE MARKS FEES.

Board of Trade, September 25th, 1914.

The Board of Trade have given a general licence permitting all persons resident, or carrying on business, or being in the British Dominions, to pay any fees necessary for obtaining the grant, or for obtaining the renewal of patents, or for obtaining the registration of designs or trade marks, or the renewal of such registration in an "enemy country," and also to pay on behalf of any "enemy" any fees payable on application for or renewal of the grant of a British patent or on application for the registration of British designs or trade marks or the renewal of such registration.

COMPETITION WITH GERMANY AND AUSTRIA-HUNGARY.

Board of Trade Action.

Attention is directed to page 946 of this issue, on which appears an abstract of a second list, issued by the Board of Trade, of articles which inquirers desire (a) to purchase, and (b) to sell. The first list is referred to in the September 15th issue of this Journal, pages 847 and 896.

PROCEDURE TO BE OBSERVED IN CONNECTION WITH THE USE IN MANUFACTURES OF SPIRITS ON WHICH DUTY HAS NOT BEEN PAID.

Sect. 8 of the Finance Act, 1902.

A memorandum on the above subject, prepared by the Board of Customs and Excise, was printed in the September 15th issue of this Journal, page 880.

Sydney Section.

Meeting held at Sydney on Wednesday, 15th July, 1914.

PROF. C. E. FAWSITT IN THE CHAIR.

A THERMO-REGULATOR FOR THERMOSTATS AT TEMPERATURES VERY CLOSE TO ROOM TEMPERATURE.

BY CHARLES W. R. POWELL.

When the temperature of a thermostat containing water is to be maintained above room temperature, the addition of heat is necessary and for this purpose different forms of thermo-regulators are in use.

If a temperature below room temperature is desired, a Foote regulator may be employed. This regulator allows a stream of ice-cold water to circulate through the bath if the temperature becomes too high but diverts the stream if the temperature is too low.

Both these types of regulator are sensitive and by their use an accurate adjustment of temperature is possible, provided that the temperature desired is not too close to room temperature.

If a temperature of say 30° C. is desired when the room temperature is 27° C., it is rather difficult to arrange a gas flame which will not be too readily blown out and not give more than the amount of heat required. However, even if a suitable flame is obtained and the bath should then become slightly overheated, the time taken to fall to the correct value will be longer than is desirable, owing to the small difference in the temperatures inside and outside the bath. A similar case arises with thermostats maintained at a temperature slightly below room temperature.

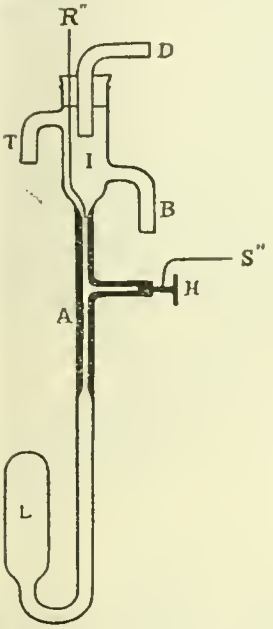

Fig. 1.

To meet such cases as these the thermo-regulator here described was designed; the essential feature is the provision for both the addition and removal of heat by means of the one regulator. The heating is carried out by one or more electric lamps and the cooling by running in ice-cold water to the thermostat.

A part of the regulator used (Fig. 1) is similar to the ordinary gas regulator. The bulb, L, is filled with toluene, and mercury is then poured in till it occupies the lower part of L and the whole of the U-tube and capillary, A. The height of the mercury in the capillary tube is adjusted by means of the screw, H. A glass tube, D, carries ice-cold water into the top chamber of the regulator, I, which is provided with two outlets, B at the bottom and T at the top.

The switch that regulates the supply of heat is shown in Fig 2. R and S, the two arms of a small electromagnet with a soft iron core, are joined to the terminals, R′ and S′. Two wires, R″ and S″ (Fig. 1), lead to R′ and S′; an accumulator or cell being placed in the circuit. Heat is applied to the thermostat by means of an electric globe lamp, which is suspended in the bath. One wire from the lamp enters the switch at C′ and leaves it at D′. C′ is joined to the brass pin, C, and D′ to the fixed metal piece, D. N is a small strip of wood pivoted at P. Opposite the poles of the electromagnet a strip of iron, M, is attached to N. A wire passes from D along N and terminates in a brass strip opposite to C. The portion of this wire between D and the wooden bar is coiled and serves as an extended spring to keep N away from the electromagnet when the latter is not magnetised. It was sometimes

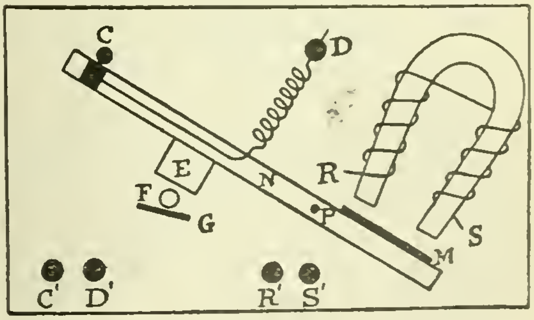

Fig. 2.

found necessary to place a piece of paper between the poles of the magnet and the strip of iron, M, in order to prevent the latter being still attracted by the magnet after the magnetising current had been broken.

A rubber tube attached to the lower outlet, B, of the upper chamber, I, of the regulator (Fig. 1) passes through F (Fig. 2), which is a hole bored in the wooden base of the switch, and thence runs to a sink. The top outlet, T, runs direct into the bath.

When the temperature of the bath is correct, the mercury in A (Fig. 1) stands just below the end of the wire, R″. If the temperature rises the mercury rises and touches the end of R″, thus completing the circuit, producing the electromagnet, RS, which then attracts the strip of iron, M (Fig. 2) and breaks the lighting circuit at C, thus removing the source of heat.

At the same time the rubber tube leading from B (Fig. I) is squeezed flat between the metal edge, E, and the small brass pillar, G (Fig. 2). The cold water, being now unable to escape to the sink through B, commences to flow into the bath through T and reduces the temperature accordingly. As the temperature sinks to its correct value the current electrifying the magnet is broken when the mercury in A draws away from R″. The spring from D then draws the bar back to its original position allowing the water to flow to the sink and again completing the lighting circuit at C.

Dimensions of the regulator.

Diameter of A	1·0 mms. internal.	Length of A	10 cms.
B	7 mms.	I	15 cms.
I	9 mms.	L	10 cms.
D	5 mms.	overall	38 cms.
T	7 mms.		
L	20 mms.		

Dimensions of the switch.

Wooden base 18 cms. × 10 cms. × 2 cms.
N 13 cms. × 1 cm. × 3 mms.

Circulation was maintained in the bath by means of a revolving shaft carrying propellor blades.

DISCUSSION.

Mr. POWELL, in reply to questions, said the bath could be maintained within half a degree of the desired temperature. The capacity of the bath used was 3 litres. The lamp used was the ordinary carbon lamp, and the voltage of the current 240.

ON THE VOLATILISATION OF ARSENIOUS ACID FROM AQUEOUS SOLUTIONS CONTAINING HYDROCHLORIC ACID.

BY BERTRAM JAMES SMART, B.SC., AND JAMES T. PHILPOT.

It is well known that when solutions of arsenious acid in hydrochloric acid are boiled the arsenic volatilises. In the report of the Arsenic Committee this method is indeed suggested as a means of completely removing arsenic when present as an impurity in the acid. Having encountered some difficulties in preparing pure hydrochloric acid free from arsenic, it was decided to determine to what extent arsenious acid is removed on boiling from solutions of hydrochloric acid of different strength. The importance of this matter was further accentuated in carrying out a series of determinations of the arsenic in impregnated timbers, since it was desired, if possible, to extract the timber with warm hydrochloric acid and to estimate the arsenic by means of the Gützeit test.

The question has been investigated by Hinds (Eighth Intern. Congress Applied Chem., 1912, **1**, 227), who found that the quantity of arsenic lost on boiling is a function of the concentration both of the arsenic and of the acid. With the concentrations usually employed in qualitative analysis the loss of arsenic on boiling the solution to half its bulk may be disregarded.

At the time this work was carried out it was not possible to obtain a full account of Hinds' results, and since the concentration of solutions of hydrochloric acid changes with evaporation it was decided to carry out a series of fractional distillations of solutions containing varying quantities of arsenious acid and hydrochloric acid, the distillates in each case being titrated to determine the quantities of hydrochloric acid and arsenious acid which had passed over.

For this purpose 200 c.c. of solution were placed in a flask fitted with a still-head to prevent splashing, and connected to a condenser. The distillates were received into small flasks in equal fractions of 20 c.c., the last 20 c.c. being left undistilled.

A series of solutions was studied, the concentrations being arranged as nearly as practicable as follows :—

Arsenious acid :—	grms. per litre.
Series I.	1·0
,, II.	0·75
,, III.	0·5
,, IV.	0·25
Hydrochloric acid :—	grms. per litre.
A.	220—230
B.	210
C.	190
D.	160

In this way the behaviour of hydrochloric acid above and below the concentration corresponding to the constant boiling mixture was studied with varying concentrations of arsenious acid.

It should be mentioned that the experiments were carried out at an altitude of 3,000 feet above sea level *i.e.* under a pressure of about 676 mm.

The results are shown in the following curves indicating :

1. Concentration of arsenious acid and hydrochloric acid in the liquid remaining undistilled after each fraction.
2. Ratio of the above concentrations compared against the concentration of hydrochloric acid in liquid remaining undistilled after each fraction.

Conclusions.

1. Solutions containing hydrochloric acid and arsenious acid when distilled give off the arsenic more rapidly the greater the concentration of hydrochloric acid.

2. When the hydrochloric acid is present to the extent of about 190 grams per litre or more, the concentration of arsenic in the solution remaining undistilled rapidly fall as the liquid is fractionated.

3. With solutions containing less than 180 grams o hydrochloric acid per litre, the concentration of arseni in the solution remaining undistilled rises, althougl some of the arsenic passes over, the ratio between aci and arsenic remaining practically constant until th solution contains about 185 grams of HCl per litr It is worthy of note that this point would correspon to a hydrate, $HCl.10H_2O$.

When the acid becomes more concentrated the pro portion of arsenic volatilised increases rapidly.

Experiments are being put in hand to study this subje by means of actual measurements of the vapour pressu of both arsenious acid and hydrochloric acid, with a vie of ascertaining whether any further evidence can b obtained as to the possible existence of this hydrate hydrochloric acid.

DISCUSSION.

The CHAIRMAN said he was interested in the referen to a hydrate of the composition $HCl,10H_2O$. It h already been shown by J. Gibson a few years ago th the specific electrical conductivity of hydrochloric ac solutions showed a maximum value at the poi $HCl.10H_2O$.

Mr. T. STEEL thought the author had very clea indicated one of his main points, namely the large p portion of arsenic volatilised with higher concentratio But it was puzzling to see two scales of figures—grn per litre and grms. per 200 c.c. ; would it not be bet to express all the results in grams per litre ? The aut

Diagram 1.

Ratio between arsenious acid and hydrochloric acid. Continuous line.

had worked with acid containing much larger proportions of arsenic than were usually met with in commercial acid; but what would be of greater interest was to know what became of the arsenic in commercial acid when submitted to similar treatment. He asked what was the significance of the ratio 100×As/HCl?

Dr. G. **Harker** said that in carrying out an investigation as to the rate of removal of arsenic, one would expect to find some relation to the constant boiling strength, but the results did not seem to show any. He pointed out that it would be possible to calculate the vapour tension of the arsenic from the weight present in a known volume of solution.

Mr. **Smart**, in reply, referring to Mr. Steel's question about the ratio column, said he thought this expressed in a better way than any other the effect of acid concentration on rate of volatilisation. He had worked with different degrees of concentration of arsenic, and as he had found a similar character for each curve, he thought it not unreasonable to conclude that the results would still be similar at lower degrees of concentration. With regard to acid of constant boiling strength, it was at first thought that there might be some relation between this and the rate of volatilisation of arsenic, but such was not found to be the case.

Communication.

THE WAXES OF TEXTILE FIBRES AND THEIR BEHAVIOUR IN THE BLEACHING PROCESS.

BY S. H. HIGGINS, M.SC.

The flax stalks as they are taken from the fields are first subjected to the retting process and afterwards undergo such operations as breaking, scutching, hackling and preparing. Each of these treatments separates some of the adventitious components of the flax, but still the fibre going through the spinning process has a large amount of non-cellulose matter attached to it. For example, on extracting linen yarn with organic solvents a wax is separated. Hoffmeister (this J., 1903, 639) stated that the flax wax extracted by benzene contains principally an unsaponifiable residue (70—80%) similar to ceresin and consisting of hydrocarbons, ceryl alcohol and phytosterol. The rest consists chiefly of a mixture of fatty acids and also a small quantity of a volatile aldehyde-like substance. Then Hodges (Pro. Roy. Irish Acad. 3, 460) and Cross and Bevan (Jour. Chem. Soc. 57, 196) found that the green wax extracted from linen yarn by alcohol contained 0·09% of nitrogen, 1·7 of mineral matter and 7·0 of phosphoric acid. Saponfication with alcoholic potash showed a large amount of cerylic alcohol and also a mixture of ketones. A large number of extractions of linen yarn and cloth by solvents were now made.

Extraction of linen by solvents.

A hank of 50's weft yarn was extracted in a Soxhlet apparatus for two days with ether. It was then dried in the air and extracted for two days with benzene, then similarly treated with ethyl alcohol for two days. After this treatment it was thoroughly dried in a stove and weighed. The yarn was not stove dried before extraction because of the danger of volatilising some of the constituents of the yarn, *e.g.*, the volatile aldehyde mentioned above. This aldehyde could be plainly noticed in the ether extract for on evaporating off the ether and warming the residue the vapour produced caused coughing just as acetaldehyde does. During the extraction with benzene the liquid became yellow but only very gradually, showing that only a small amount of matter remained for the benzene to dissolve out. Indeed, it seemed possible that on continuing the extraction with the ether long enough all the matter which the benzene removed would also be dissolved out by the ether, but although this point was tested at least six times, it was always found that after the ether extraction benzene dissolved out more wax. For example, a hank of dew retted yarn gave up 0·92% of wax to ether on extracting two days and a further 0·27% on after treatment with benzene for the same time. The melting point of the wax lies between the boiling points of ether and benzene, hence the hot benzene by melting the wax dissolved it much more quickly. The wax extracted by the ether was light yellow and sometimes bright green, but on melting it assumed somewhat the same colour as that produced from the benzene extract. On extracting the same yarn with (1) ether, (2) petroleum ether, (3) gasoline, and (4) benzene, it was seen that the lower the boiling point of the solvent the lighter the colour of the extracted wax. The darkening of brown cotton and linen cloth on heating is due to the melting of the wax, which thus changes in colour from yellow to brown. The alcoholic extract was dark coloured, and on cooling separated a large amount of the wax. On evaporating off the alcohol, the residue was brownish and had a strong smell. At this point the observation (to be described later) that brown linen after extracting with benzene yields more matter to the benzene if soured, washed and dried must be mentioned. Any matter of a saponaceous nature in the linen would be taken up by the alcohol. The linen yarn after the three successive extractions did not show much alteration except that it was a little lighter in colour, but a dark green sample of yarn became much browner on extracting the wax (dark green) from it. After the alcohol extraction the yarn was treated with hot distilled water until apparently no more matter was removed. The extract obtained evaporated to dark brown brittle scales. On boiling with ammonia a large amount of matter was now separated from the fibre, yet most of the non-cellulose matter still remained attached to the fibre in spite of long treatment with the boiling ammonia. Even further treatment with sodium hydroxide did not remove these matters entirely so that the treatment was finished by boiling under pressure with sodium hydroxide solution, the drop in weight being in this case obtained by weighing the yarn before and after treatment. After washing the yarn was extracted with pure hydrochloric acid and the weight of the matter extracted was obtained by evaporation. The following results were obtained:— Extracted by ether, 1·39%; benzene, 0·29%; alcohol 0·49%; water, 2·03%; ammonia, 3·27%; NaOH afte pressure boiling, 14·06%; HCl, 0·33%.

If the brown linen had been treated with all the reagent mentioned and not successively in the order given, quit different results would have been obtained. Thus th benzene would remove all the matter which the ethe extracted besides that stated above; the alcohol woul also account for most of the matter taken out by th benzene. Water had no apparent effect on the wa taken out by benzene, for linen before and after boilin with water under pressure had the same wax content but water might have some effect on the saponaceou matters mentioned above. Linen cloth boiled with wate under pressure showed a drop of 3·3 to 4·5%, but this als included the size of the warp yarn. Sometimes the clot became greener in colour owing to the removal of dar brown matter. Again, ammonia and sodium hydroxi would have removed a large amount of the waxy matte if they had not been previously extracted, and furth experiment showed that brown untreated linen extracting with cold dilute hydrochloric acid for thr hours then, evaporating and incinerating the residue, ga 1.10% of matter extracted.

Of the extracts obtained, those taken out by ethe benzene, and alcohol separated from solution on coolin The wax obtained from the ether and benzene extrac on melting and cooling, showed a peculiar fracture and t wax obtained from brown linen by alcohol showed t same peculiarity. The alcohol extract in the abo tests, however, was sticky and golden brown in colo After these three extractions the linen had no percepti smell. Similarly jute gave up 0·9% of a greenish brow strongly smelling oil, the extracted fibre having no smell.

After a number of extractions it was noticed that wat retted flax contained more wax than dew retted, e. 1·89%, water retted; 1·19%, dew retted. This differe in the proportions of wax in the two classes of fibre is interesting, since these waxy matters are supposed to be products of the decomposition of cellulose bodies during the retting and other processes. It is also known that water retted yarn becomes cream coloured and dew retted greyish on treatment with alkalis.

From a large number of extractions the author found that benzene took out from 1·57 to 1·95% of wax from brown linen. The water extract from linen cloth was found to be only slightly combustible and to contain some tannic acid and a trace of starch.

Effect of the extractions on the tensile strength of the yarn.

After each of the extractions above described a number of yarns were separated and kept to ascertain their breaking strengths. They were all left in the air for three days and thirty yarns from each sample were broken in a Schopper testing machine (Higgins, this J., 1911, **30**, 1295) to give the following average results :—

	Breaking strength.
Original yarn	730 grms.
After ether extraction	790 ,,
,, benzene ,,	750 ,,
,, alcohol ,,	720 ,,

It is seen that the extraction with ether caused an increase in strength of the yarn. Knecht (J. Text. Inst., 1911, **2**, 22—29) has shown that for cotton the addition of waxes causes a decrease in the breaking strength due probably to the slipping of the fibres and the above results show that the ether removes the excess of wax which evidently causes a slipping of the fibres. Further extraction by benzene produces a decrease of tensile strength, the benzene apparently extracting certain waxy matters which have a consolidating effect on the fibres. Yet after the benzene extraction the yarn is stronger than the original yarn. The treatment with alcohol brings the strength down to the original value or a little lower. Other tests gave the following results :—

	Water retted flax. Strength.	Dew retted flax. Strength.
Original yarn	1130 grms.	1450 grms.
Extracted by ether	1410 ,,	
,, ,, benzene	1200 ,,	1420 ,,
,, ,, alcohol	1100 ,,	1450 ,,

The results with the water retted yarn are similar to those previously given, but in the case of the dew retted flax the extractions had little apparent effect on the strength. It has been stated above that dew retted yarn contains less wax than water retted and the wax which causes the slipping of the fibres in the latter yarn may not be present in the former.

Other tests were the following :—

	Strength.	Wax extracted.
		%
Original yarn	801	—
Extracted by ether	832	1·42
,, ,, petroleum ether	826	1·03
,, ,, benzene	816	1·52

	Strength.
Original yarn	850 grms.
Extracted by benzene	1020 ,,
do. then boiled with water	1020 ,,
,, by ether	1080 ,,
,, ,, carbon disulphide	940 ,,
,, ,, ,, tetrachloride	960 ,,
,, ,, alcohol	880 ,,
,, ,, alcohol and water	860 ,,
,, ,, ligroin	910 ,,

Linen yarn of strength 730 grms. was put into bleaching powder solution to "cream" it, then soured, washed well nd dried, when it was found to have decreased to an verage strength of 610 grms. From the figures given it is evident that the removal of the wax increases the tensile strength of the linen, and it may be for this reason that lye-boiled linens are sometimes stronger than the original goods, since much of the wax is removed during the boiling with alkaline solutions (Higgins, this J., 1911, **30**, 1295). Experiment showed that this wax was apparently emulsified by resin soap solution and by benzene brought into an emulsion in water by Turkey red oil, so that an attempt was made to increase the strength of linen yarn by treatment with these solutions. At the same time this treatment gave the yarn somewhat the same handle as is aimed at in boiling yarns before weaving. In an actual test the original yarn was of 730 grms. strength and this was found to drop to 670 grms. (resin soap) and 650 grms. (benzene emulsion). So that this treatment did not achieve the purpose for which it was designed.

Effect of the bleaching process on the amount of wax retained by the fibre.

Pieces of linen were taken out at certain definite stages during the bleaching process and washed and dried. Their wax was extracted by benzene to give the following results :—

	Wax.
	%
Original linen	1·47
After water boiling	1·42
,, lime boiling and souring	1·59
,, 1st lye boil	0·25
,, 2nd lye boil	0·11
,, 1st chemic	0·11
Fully bleached	0·036

The stages mentioned are not the total number of operations, but definite points chosen for the tests. When a piece of linen cloth was taken out of the lye boil, for example, it was washed, dried, and weighed, then extracted. The percentage of wax was not then calculated on the weight found, but on the weight of the brown linen to which this lye-boiled linen corresponded. To arrive at these figures a parallel series of tests had to be carried out, showing the drop in weight of the linen at the different stages mentioned. The figures show that the wax is gradually eliminated during the bleaching until the fully bleached linen contains only a very small amount. A large number of tests showed that this amount varied from 0·02 to 0·045%. After the lime boil the wax is greater in amount than before this operation, but it must be remembered that the linen after lime boiling was soured and that, as before mentioned, linen treated with acid gives up more wax to benzene than untreated linen. Moreover, if during the saponification of the waxes by lime the alcohol liberated during the formation of the lime soap was insoluble and was deposited on the fibre, this might affect the figures obtained. A large number of experiments were carried out to determine this increase of weight of the wax during lime boiling. In one case the wax in the brown linen was 1·65% and after lime boiling and souring 1·88%. On souring the brown linen before extraction, however, the amount of wax was 1·81%, which amount considering the above explanation is very near that for the lime boiled linen. The lack of effect of the chemic on the weight of the wax present will also be referred to later. The wax after this process was of the same colour as that extracted from the linen after the second lye boil and fractured on cooling in the same peculiar manner as the original wax did. These waxes were all brownish and the extracted linen in all cases was lighter in colour due to the removal of the brown wax. Linen lye boiled without previous lime boiling gave 0·9% of wax.

The property of linen in yielding more wax to benzene after souring was tested for in the case of cotton yarn. American cotton yarn was extracted with benzene for four days and yielded 0·503% of wax. On putting in warm dilute hydrochloric acid for a few minutes, washing well with boiling distilled water, drying and again extracting a further 0·058% of wax was eliminated. Cotton therefore behaved exactly like linen in this respect

Saponification of the waxes.

The wax from brown linen was found to contain 72·2% of unsaponifiable matter and 27·8% saponifiable. The wax extracted from the linen after lime boiling and souring contained 40·0% of saponifiable matter. This point was carefully investigated by a large number of experiments. Thus it had been previously found that on extracting brown linen with ether for two days only 78·5% of the wax was removed, whereas lime boiled and soured linen yielded 95·7% of its total wax in the same time. It therefore appeared that the waxes were changed during the lime boiling. A piece of linen cloth was now lime boiled and washed thoroughly but not soured. It was then extracted with benzene, the unsaponifiable part of the wax being thus removed; the lime soap produced during the lime boil by the union of the lime and the saponifiable part of the wax still remained on the fibre. The linen was now soured and washed well, then dried and extracted. It was found that the sum of these two extracts equalled that obtained by souring at first and extracting. Moreover, 40% of the wax was again found to be saponified during the lime boiling. Further experiment showed that the difference between the proportion of saponifiable matter in the waxes before and after the lime boiling was due to the fact, previously mentioned, that brown linen has to be soured before yielding up all its wax. A piece of brown linen extracted with benzene gave 0·55 grm. of wax and on souring, drying and again extracting a further 0·10 grm. of wax. Applying this result to the figures obtained in the previous test we have :—

Wax extracted by benzene	0·876	grm.
do. after souring	0·16	„
Total wax	1·036	„
Saponifiable portion	0·246	grm.
do. adding wax after souring	0·16	„
Total saponifiable wax	0·406	„
Unsaponifiable wax	0·63	grm.

Making the correction shown it is seen that from 1·036 grms. of wax 0·406 grm. is saponifiable which accounts for the 40·0% observed after the lime boiling. The melting points of the waxes were found after the lime boil to be:—before souring, 80—82° C.: after souring, 65—67° C., but the points were not definite.

The wax after the first lye boil was still a mixture of saponifiable and unsaponifiable matter and the effect of the chemicing was, as described later, to make the wax more saponifiable.

Similar tests to the above were also performed on cotton yarn. Hanks of yarn were boiled with lime under pressure, washed well, extracted with benzene then soured and again extracted when it was again found that the sum of the amounts of wax extracted was approximately equal to the wax obtained on souring directly after liming and then extracting. It was also noticed that the wax extracted before souring was dark brown and brittle whereas after souring the wax obtained was much softer.

The effect of successive lime and lye boils on the waxes.

To test the effect of different boiling agents on the yarn the following tests were made. Hanks of linen yarn 55's weft were stove dried and weighed, then boiled with lime and lye (a mixture of sodium hydroxide and sodium carbonate) under pressure in the order given. They were then well washed, dried and weighed. The weight of wax still present in each hank was found :—

	Decrease in weight.	Wax.
	%	%
(1) Lime, lye, lye	21·8	0·06
(2) Lye, lime, lye	23·1	0·046
(3) Lye, lye, lye	22·1	0·16

It was noticed that (3) was by far the dullest in appearance and the figures show that it contained much more wax than the other two hanks. The lime boil has long been a topic of argument between chemists and bleachers. The former state that caustic soda is the best saponifying agent and the latter reply that the lime boil cannot be replaced for certain classes of goods. It is well-known to those engaged on bleaching that if any classes of cottons are coming up soft in the finishing a resort to lime-soda ash boiling in place of caustic soda soon puts them right. Lime boiling is not a mere survival of the days of empiricism: it is the best treatment for some classes of goods for the figures given show that it is the best means of removing the waxy matters from the cloth. It was noticed on putting lime boiled and soured cloth into hot alkali solution, even for only a short time, that a large amount of matter was separated from the cloth and its wax contents considerably reduced; this is probably due to the unsaponifiable and saponifiable constituents of the wax existing together the alkali producing a soap with the latter, and at the same time removing some of the former constituent by disturbing it and producing an emulsion. The soap is produced quickly as the fatty acid is free (unlike the wax in the linen not lime boiled) and a concentration of the soap in the neighbourhood of the unsaponifiable wax is produced. It is well-known that soaps are useful in removing these waxes and the case mentioned is evidently one where the action of the soap is very effective.

The steeping and chemicing of cloth without boiling.

Many methods of bleaching without boiling the goods have been from time to time suggested. An investigation of the statements made concerning these methods was now made. 65·3 grms. of linen which were found to weigh 60·69 grms. when stove dry were placed in 500 c.c. of water along with 3% soda ash and $\frac{3}{4}$% Turkey red oil and heated to 80° C. for two hours. The cloth was then rinsed, washed well and the operation repeated, using a freshly prepared bath. It was again washed well and then put into a solution of bleaching powder solution for four hours. By titrating the solution before and after the bleaching it was found that the cloth had required 2·87 grms. of chlorine to bleach it. A similar piece of lime and lye boiled linen required 0·55 grm. of chlorine to bleach it, so that to bleach by the steeping method would require more than five times the amount of bleaching powder that the ordinary method requires. Since bleaching powder is the most expensive chemical the bleacher uses and represents a large proportion of the cost of bleaching, the bleaching powder required for the steeping method would make that process extremely costly and there is also the cost of the soda ash and Turkey red oil to add. Even after the treatment mentioned the linen was still yellow and unsuitable for any market. Moreover, on boiling it and chemicing to produce a fair white it lost a great amount in weight. It contained 0·32% of wax, which is enormously greater than properly bleached linen, and the small gain in weight at which the steeping process aims had only been achieved by retaining much of the original impurities of the fibre. The author has shown (this J., 1911, **30**, 1295) that the drop in weight during bleaching takes place during the boiling operations if the process is properly conducted, and the figures given above show that good boiling is the cheapest way of getting rid of th impurities of the cloth besides being the only way t produce a good white. If the bleaching is properl conducted the weight and strength must be equal to that o linen bleached on the grass, that is, without the applicatio of any bleaching powder solution (*loc. cit.*).

Bleaching tests on wax-extracted linen showed tha the extraction of the wax did not hasten its bleachin to any large extent. Brown linen (untreated and als wax-extracted) and lime-boiled and soured line (untreated and also wax-extracted) were placed in th same solution of bleaching powder, when the rate o bleaching was only slightly greater on the wax-extracte material.

The effect of various additions to the boiling liquors.

On heating linen wax with water it melted, but di not form a good emulsion. On adding a little Turke red oil to the water a good emulsion was produced: resi soap had the same effect. The addition of these tw substances to boiling liquors ought therefore to assist i the removal of the waxy matters from the cloth. large number of experiments were performed to ascertai if this were the case. Thus a piece of linen was boiled in caustic soda solution and then divided into two parts: one part was further boiled in caustic soda containing resin soap, then both portions were washed and dried. On extracting the wax that remained in each piece of cloth the amount was found to be about the same, pointing to the conclusion that the resin soap had not assisted in the removal of this wax. It was found, however, that even after washing well some resin remained in the cloth and interfered with the test.

Recently a number of substances have been introduced for adding to the boiling liquors in order to eliminate the waxy matters of the cloth. Benzene is the substance used in some of these, whereas in others a liquid of similar properties is used. In order to make these liquids mix with water, Turkey red oil and other substances are used, for in this way an emulsion is formed which does not readily separate. These preparations act splendidly in extracting the waxy matters from cloth placed in them, but the author finds that their cost does not admit of extensive adoption on the large scale.

The effect of hypochlorites on the waxes.

Previous tests showed that the weight of wax in linen cloth was not appreciably affected by the chemicing process, and further experiment confirmed this conclusion. The process of "creaming" linen yarn was now carried out by leaving linen yarn immersed in strong bleaching powder solution until it became of a cream colour. It was then soured, washed well and dried. A decrease of 9% in weight and 16·1% in tensile strength was found. This process of "creaming" cleans the yarn of a certain amount of straw and other matters, making it better for weaving and causing less weaving faults. During the "creaming" the yarn rapidly changed colour, and a thick precipitate of calcium carbonate was formed from the carbon dioxide produced by the oxidation of some of the constituents of the yarn. This oxidation is a selective one, the non-cellulose portion of the yarn and also the pectocelluloses being attacked before the cellulose of the fibre proper, but if long continued the latter is also attacked. The amount of bleaching powder required for this operation of creaming makes the method very costly, as can be understood from figures previously given (p. 904). The drop in weight of 9% is made up of 1·01% due to the hydrochloric acid (p. 902), 2·03% due to the hot water washing, and 5·96% due to the actual oxidation.

The "creamed" yarn was now extracted by benzene and found to contain 1·21% of wax on the original weight of the yarn. This wax was of a brownish colour and apparently little different from the original wax. It was saponified by alcoholic potash, when a white powder (evidently potassium chloride) separated out. The alcohol was evaporated and the residue washed well through a filter paper to remove the soap. The filter paper was dried and extracted with benzene to obtain the unsaponifiable matter, while the fatty acid was separated from the filtrate.

Unsaponifiable matter	11·21%
Saponifiable matter (fatty acid)	59·79%

There was a disappearance of some of the wax, as seen from the figures; it is probable that during the "creaming" the wax became chlorinated and afterwards lost this chlorine to produce potassium chloride during saponification. At any rate it is evident that the chemicing process changed the wax into products which yielded to a larger extent to saponification, and thus explained the observation that chemicing prepares the impurities of linen for subsequent removal by "scalding." Cotton was now "creamed" in the same way as linen until a fair white was produced. Extraction by benzene gave 0·52% of brownish wax which fractured on cooling just as linen wax did. On saponifying with alcoholic potash the wax behaved just as had been noticed for the linen wax, potassium chloride separating:—

Weight of wax treated	0·170 grm.	
,, ,, ,, unsaponifiable	0·040	0·123 grm.
,, ,, fatty acids	0·083	

As a confirmation of these results linen yarn was left in bleaching powder solution until almost white before souring, washing, drying and extracting with benzene. The figures in this case were:—

Weight of wax treated	0·3800 grm.	
,, ,, ,, unsaponifiable	0·2035	0·2145 grm.
,, ,, fatty acids	0·0110	

The results point to the wax taking up chlorine during chemicing and becoming changed.

In all the investigations described above it is probable that the deductions from the experiments with linen can also be applied to cotton, for in all cases where the two fibres were carefully compared they behaved remarkably alike.

Obituary.

EDWARD RILEY.

Edward Riley died at Marlow, on the 12th inst., 83 years old. His education was obtained at King's College School, The Putney Engineering College, and later as regards chemistry from Dr. Lyon—afterwards Lord—Playfair, to whom he became assistant. In 1853 he went to Dowlais as research chemist, and while there conducted the first experiments on the Bessemer process; but in a few years he started a private practice as an analytical and consulting chemist, which he followed until the end. He, however, assiduously maintained his association with the Bessemer process, hence figured actively in its various stages of progress, and at the appearance of the basic process, along with Thomas and Gilchrist, he was interested in it as patentee, and later as investigator as well as director of companies working it. He was author of many contributions relating to the chemistry and technology of iron and steel; several of these appeared in the Journals of the Chemical Society and of the Iron and Steel Institute. The latter institute awarded Riley its Bessemer Gold Medal as recently as May last. He was an original member of this Society.

Journal and Patent Literature.

PATENT SPECIFICATIONS may be obtained by post by remitting as follows:—
English.—8*d*. each, to the Comptroller of the Patent Office, W. Temple Franks, Esq., Southampton Buildings, Chancery Lane London, W.C.
United States.—1*s*. each, to the Secretary of the Society.
French.—1 fr. 05 c. each, as follows: Patents dated 1902 to 1907 inclusive, Belin et Cie., 56, Rue des Francs Bourgeois, Paris (3e.); Patents from 1908 to date, L'Imprimerie Nationale, 87, Rue Vieille du Temple, Paris.
German.—1 mark each (with full particulars) to Kaiserlich Patentamt, Berlin, German.

I.—GENERAL PLANT; MACHINERY.

Liquids in tanks; Apparatus for sampling ——. E. Schmitz. Les Matières Grasses, 1914, 7, 1914—4194.

THE apparatus consists of a 3-litre cylinder, containing a suction piston, suspended from a winch by a chain which passes from the bottom of the cylinder over the pulley of a counterweight below, the other end of the chain being connected with the top of the piston rod. As the cylinder is drawn upwards through the liquid, the piston rod is simultaneously raised, and the liquid is drawn into the cylinder. It is also possible to maintain the cylinder at any desired height in the liquid, as shown by an outside indicator, and to raise the piston without altering the position of the cylinder.—C. A. M.

PATENTS.

Distillation or evaporation of liquids or solutions. T. Boberg, O. Söderlund, N. Testrup and The Techno-Chemical Laboratories Ltd., London. Eng. Pat. 13,607, June 12, 1913.

IN evaporating apparatus of the type described in Eng. Pats. 12,462 and 22,670 of 1911 (this J., 1912, 971, and 1913, 183), the work of evaporation is so distributed between two systems of evaporators that the steam required for the compressor is obtained from the first system. The second evaporator, which may be of the film type, is heated by exhaust gases from the gas engine which supplies power for the system, and an internal combustion pump is used as a source of energy for the compressor and for circulating the liquids.—W. H. C.

Evaporating apparatus; Liquid ——. A. Chapman, Liverpool. Eng. Pat. 17,145, July 26, 1913.

LOW-PRESSURE steam is withdrawn from the steam space of a tubular evaporator by an injector actuated by an external supply of high-pressure steam and fixed in the centre of the upper tube-plate, so that the low-pressure steam inlet is above the liquid level. The low-pressure steam is compressed and introduced with the high-pressure steam into the space surrounding the heating tubes of the central chamber. (Reference is directed to Eng. Pat. 2967 of 1878.)—W. H. C.

Evaporating apparatus; Multiple-effect ——. R. Lougher, Papaikou, Hawaii. U.S. Pat. 1,105,443, July 28, 1914; date of appl., June 28, 1912.

A NUMBER of superposed evaporator sections are separated by spaced sheets between which are water-condensing spaces, and a pan is placed below the bottom section. Each section has an inlet above to receive the liquid to be treated and an outlet below, and is fitted with open vapour tubes extending downwards acoss the water-condensing space and connected with the lowermost sheets. Evaporating tubes closed at their upper ends and arranged over the vapour tubes, are supported at their lower ends in the uppermost sheets, extend through each section and communicate with the water-condensing spaces. Pipes leading from these spaces are connected with a main pipe. A pipe leading from the water-condensing space of the uppermost evaporator section, and the above-mentioned main pipe, are connected with an auxiliary evaporator.—L. E.

Rotary furnaces or the like; Removing sediments or crusts from ——. N. Ahlmann, Copenhagen. Eng. Pat. 16,893, July 23, 1913. Under Int. Conv., Feb. 1, 1913.

THE crust or clinker is removed by means of a disc which carries a number of consecutively acting scrapers and which is rotated within the furnace about an axis oblique to the axis of the furnace.—W. H. C.

Kiln; Rotary ——. H. E. Riisager, Frederiksberg, Denmark. U.S. Pat. 1,103,381, July 14, 1914; date of appl., April 18, 1912.

THE lining of the shell of a horizontal rotary kiln is partly replaced by chambered blocks secured to the shell by hooks and an angle iron and forming a corrugated transversely longitudinal partition.—W. H. C.

Regenerative furnaces; Reversing ——. L. L. Knox, Allegheny, Pa., U.S.A. Eng. Pat. 25,588, Nov. 8, 1913. Under Int. Conv., May 16, 1913.

THE removable cooling box described in Eng. Pat. 8883 of 1912 (this J., 1912, 801) is so constructed that it only surrounds the upper part of the gas port, the middle portion forming the only connection between the end portions of the box. The box is inclined in order to facilitate the escape of any steam formed, has a depending hollow flange which protects the arch, and is provided with water-supply pipes which enter the end of the box and discharge near the centre.—W. H. C.

Churns or other mixing and agitating apparatus. R. M. Williams, Oswestry, Salop. Eng. Pat. 18,055, Aug. 8, 1913.

THE barrel of the churn has hollow trunnions mounted on a frame and is rotated from a countershaft by toothed wheel gearing, the beaters being rotated in the opposite direction by a chain and sprocket wheel driven from the same countershaft. The shaft on which the beaters are mounted can be withdrawn by removing a wedge key, leaving the beaters free to be taken out, without disturbing the sprocket wheel.—W. H. C.

Mixing machine. A. McKaig, Buffalo, N.Y. U.S. Pat. 1,105,812, Aug. 4, 1914; date of appl., Oct. 15, 1912.

A HORIZONTAL drying drum has a shoot at the outlet end which is connected with a discharge spout. A door, which forms part of the wall of the spout, rotates about a transverse shaft so that when it is turned inwards the spout is closed to the air but open to the shoot, and when it is turned outwards the spout is open to the air and closed to the shoot.—W. H. C.

Catalysis; Apparatus for facilitating chemical reactions by means of ——. H. A. A. J. Lelarge, Paris. Eng. Pat. 18,579, Aug. 15, 1913.

A NUMBER of open spirals of constant pitch, *e.g.*, of metal or of porous material impregnated with the catalyser, are arranged in layers in a vessel, alternate layers being at right angles to one another. The top and bottom layers are formed of a material which is a good conductor of electricity and are connected with the poles of a battery or other source of electricity. The intermediate layers are formed of non-conducting material. —W. H. C.

Pulverising, gasifying and re-heating liquefied gases; Apparatus for ——. J. L. Laurent, Paris, and L. Peltier, Clichy, France. Eng. Pat. 18,621, Aug. 15, 1913. Under Int. Conv., Aug. 21, 1912.

THE liquefied gas (*e.g.*, carbon dioxide) is passed direct by a pipe reaching to the bottom of the reservoir, through on or more gratings, to a pulveriser situated in the lower part of a gilled expansion chamber which is suitably heated The gas then passes from the upper part of the expansio chamber through a series of coils arranged round the outside of the chamber and is heated further. The heated ga passes through a pressure-regulating valve, preparator to using it for motive power purposes.—W. H. C.

Filtering materials; Manufacture of ——. L. von Jarac zewski, Berlin. Eng. Pat. 23,736, Oct. 20, 1913. Unde Int. Conv., Dec. 7, 1912.

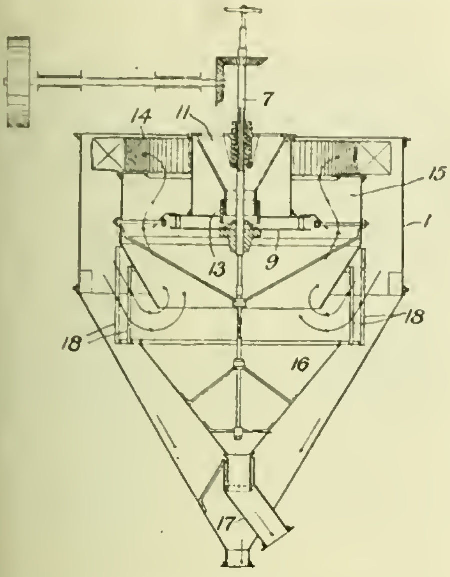
FILTERING material having a hairy surface (*e.g.*, fustia is boiled for 5 mins. in a mixture of water, alcohol, bon black and magnesia, then allowed to cool, dried and passe between heated rollers. A mixture of bone black, asbest fibre, magnesium carbonate, "perhydrol of magnesia and water is then spread on the hairy surface of the fabr which is again dried and pressed for several hours betwee sheets of glazed paper or polished metal.—W. H. C.

Filtering valuable compounds; Apparatus for ——. N. . Burgess, New York. Assignor to Butters Patent Vacuu Filter Co. U.S. Pat. 1,103,345, July 14, 191 date of appl., Sept. 3, 1913.

A FILTER-LEAF is provided with a valve which allows cle water to be discharged from the leaf into the slimes wh the internal and external pressures are equal, but whi closes and prevents the entry of liquid when the inter is less than the external pressure.—W. H. C.

Separators. C. von Grueber, Berlin-Weissensee. Eng. Pat. 27,130, Nov. 25, 1913.

The materials are fed through the hopper, 11, into the inner conical vessel, 15, where they meet a current of air produced by the fan, 14, the lighter particles being carried into the outer vessel, 1, and the heavier particles falling into the lower conical vessel, 16, and being discharged through the opening, 17. A double row of vertical curved baffles, 18, serves to prevent any of the lighter particles from returning to the inner chamber with the air. An adjustable ring, 13, fits over the lower end of the hopper above the spreader pipe, 9, and the lower cone, 16, is carried by a spider from the rod, 7, which slides within the hollow shaft so that the height of the cone, 16, can be adjusted.—W. H. C.

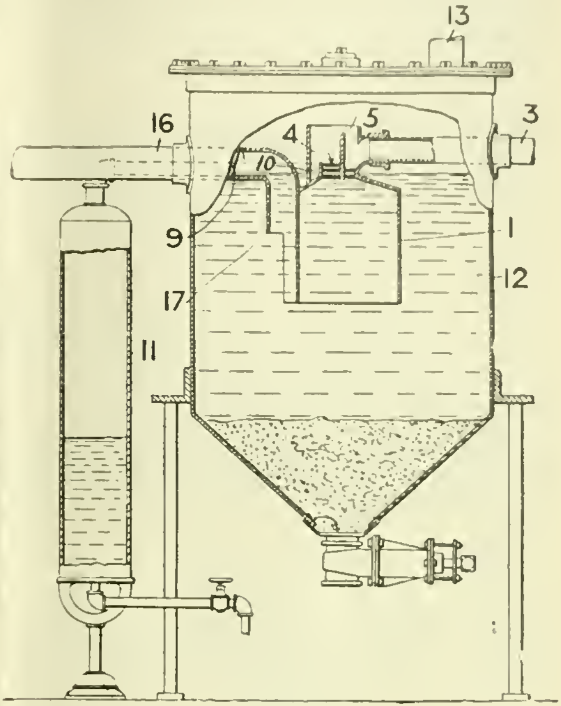


Wet-grinding; Compound mill for ——. E. C. R. Marks, London. From G. Polysius Eisengiesserei und Maschinenfabrik, Dessau, Germany. Eng. Pat. 484, Jan. 7, 1914.

The rotating drum is divided by a transverse hollow partition into two chambers, serving respectively as a granulating chamber analogous to a ball mill and a fine grinding chamber analogous to a tube mill. The liquid in the granulating chamber is maintained at a lower level than that in the fine grinding chamber, so that it has a lesser damping effect on the blow caused by the fall of the crushing bodies. The transference of the material from the granulating to the fine grinding chamber is effected by a number of curved blades in the hollow partition, which lift the material over the edge of the sill that keeps back the liquid.—W. H. C.

Separating liquids of different densities; Apparatus for ——. E. C. Kelly, Boston, Mass., U.S.A. Eng. Pat. 9955, April 22, 1914. Under Int. Conv., April 28, 1913.

The mixture of liquids enters the separator, 1, which is open above and below and is contained in the larger closed vessel, 12, through the pipe, 3, and strikes against the baffle, 5. The lighter liquid collects at the surface and enters the compartment, 4, overflows into the space, 10, and is discharged through the pipe, 9, into the receiver, 11. The heavier liquid sinks into the larger volume of heavier liquid contained in 12, and overflows through the pipe, 16, which is of such dimensions as to ensure a constant level. The large volume of liquid in 12, serves as a tranquiliser and prevents any light liquid from being carried away, and also allows any sediment to settle out from the heavier liquid. A baffle, 17, prevents any light liquid which may have escaped into the vessel, 12, from overflowing by the pipe, 16, and allows it to float up to the surface where it is volatilised and escapes through the vapour pipe, 13.
—W. H. C.



Grinding, pulverising and like mills. W. H. Kniskern, San Antonio, Spain. Eng. Pat. 5437, March 3, 1914.

To obviate the great wear and tear experienced at the angle between the liner and the plates in tube mills having peripheral liners and transverse plates, a fillet or thickened portion is provided, which is integral with either the liner, or the plate, or with both.—W. H. C.

Emulsions; Machine for producing or treating ——. Silkeborg Maskinfabrik Zenthen and Larsen, Silkeborg, Denmark. Eng. Pat. 4657, Feb. 23, 1914. Under Int. Conv., Feb. 24, 1913.

The machine consists of a horizontal drum provided with beaters and baffle-plates which are spaced alternately and rotated on a horizontal axial shaft. The beaters are transverse plates perforated with radial slots which have their edges bent outwards. The baffle-plates which are near the inlet end of the drum have radial apertures and those near the outlet end are perforated with smaller round holes.—W. H. C.

Reaction or absorption towers; Filling materials for ——. F. Raschig, Ludwigshafen, Germany. Eng. Pat. 6288, March 12, 1914.

The towers are filled with a number of small cylinders of suitable material which are simply dropped into the tower and have in consequence an irregular arrangement.
—W. H. C.

Desiccation of air or gases. Soc. l'Air Liquide (Soc. Anon. pour l'Etude et l'Exploit. des Procédés G. Claude), Paris. Eng. Pat. 11,094, May 5, 1914. Under Int. Conv., May 6, 1913.

The cooling agent, *i.e.*, the expanded gas, passes down through a nest of vertical tubes and the gas to be desiccated and cooled is passed upwards around the tubes through a spiral of very low pitch so that the path of the gas is almost horizontal. To remove any deposit of hoar frost, the region of lowest temperature is from time to time caused to shift temporarily upwards by cutting out the lower stages of the cooling coils at intervals. The rise of temperature so obtained causes the frost to melt, the water draining into a reservoir below.—W. H. C.

Drying machine. O. S. Sleeper, Assignor to Buffalo Foundry and Machine Co., Buffalo, N.Y. U.S. Pat. 1,103,443, July 14, 1914; date of appl., Oct. 2, 1912.

The materials are dried on the outer surface of a drum which is rotated on a horizontal axis and enclosed in a casing one end of which is fixed, the remainder being movable horizontally to allow access to the drum. —W. H. C.

Dry-kiln. G. F. Moranz, Chicago, Ill., Assignor to Chicago Varnish Co. U.S. Pat. 1,103,608, July 14, 1914; date of appl., April 16, 1913.

The drying chamber has valved air-inlets near the bottom, air-outlets near the top, and heating coils on the bottom. Above the heating coils is a double floor formed of removable gratings spaced apart, the bars and spaces of the upper grating being narrower than those of the lower and the spaces of the upper grating being over the bars of the lower.—W. H. C.

Drying-drum; Rotary ——. K. H. G. A. Gerlach, Nordhausen, Germany. U.S. Pat. 1,105,417, July 28, 1914; date of appl., Aug. 7, 1913.

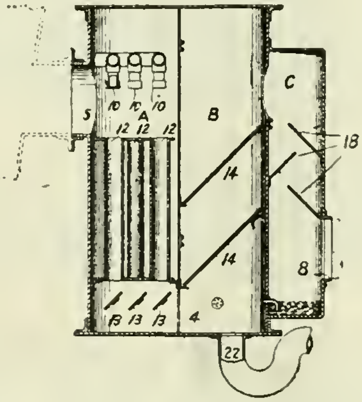
A rotary drying-drum is provided with a series of removable radial partition plates, having tangential mixing vanes on each side and supported between the shell of the drum and a series of central removable rings.—W. H. C.

Extinguishing fires; Compound for ——. W. O. Snelling, Pittsburg, Pa., Assignor to F. L. Dyer, Montclair, and J. W. Aylsworth, East Orange, N.J. U.S. Pat. 1,103,092, July 14, 1914; date of appl., June 7, 1912.

The compound consists of a non-inflammable solvent in which is dissolved a carbon compound of the aliphatic series containing a halogen atom and more carbon atoms in the molecule and having a higher boiling point than the solvent.—W. H. C.

Scrubbing and cooling gases for use in fumigating and fire extinguishing and like purposes; Apparatus for ——. G. Harker, Assignor to The Harker Fire Extinguisher and Fumigator Co., Ltd., Sydney, N.S.W. U.S. Pat. 1,103,509, July 14, 1914; date of appl., March 28, 1913.

The waste combustion gases enter the first chamber, A, of the apparatus through the pipe, 5, and are drawn into the tubes, 12, by the action of the water sprays, 10. The water spray cools and washes the gases which strike against the baffles, 13, as they issue from the lower ends of the tubes. The gases next enter the chamber, B, through the opening, 4, and pass upwards through the gauze baffles, 14; any water which may be separated being drawn off by the pipe, 22. The gases next pass down the chamber, C, provided with the baffles, 18, and are discharged through the port, 8. —W. H. C.



Distilling apparatus. J. A. Houser, Marion, Ind., U.S.A. Eng. Pat. 27,642, Dec. 1, 1913.

See U.S. Pat. 1,082,525 of 1913; this J., 1914, 127.—T.F.B.

Liquid suspended in another liquid; Process and apparatus for separating a ——. Comp. Française pour l'Exploitation des Procédés Thomson-Houston. Fr. Pat. 468,455, Feb. 14, 1914. Under Int. Conv., Feb. 18, 1913.

See Eng. Pat. 13,465 of 1913; this J., 1914, 780.—T. F. B.

Drying [gases] by cooling; Temperature exchangers for ——. Soc. l'Air Liquide (Soc. Anon. pour l'Etude et l'Exploit. des Proc. G. Claude). Fr. Pat. 468,917, May 6, 1913.

See Eng. Pat. 11,094 of 1914; preceding.—T. F. B.

Filtering apparatus. K. Kiefer. Fr. Pat. 469,041, Feb. 10, 1914. Under Int. Conv., April 8 and June 5, 1913.

See Eng. Pat. 14,136 of 1913; this J., 1914, 632.—T. F. B.

Filter-press. E. J. Sweetland. Fr. Pat. 469,108, Feb. 28, 1914. Under Int. Conv., April 12, 1913.

See U.S. Pat. 1,083,305 of 1914; this J., 1914, 341.—T.F.B.

IIa.—FUEL; GAS; MINERAL OILS AND WAXES.

Producer gas from low-grade fuels. R. H. Fernald. J. Franklin Inst., 1914, **178**, 161—179.

The total horse-power of gas producer power plants in the United States was 160,000 in 1911, of which 80,000 was obtained from bituminous coal, 70,000 from anthracite and 10,000 from lignite. Lignites usually contain much moisture, but make gas of excellent quality. Many low-grade bituminous coals and lignites may be utilised for power purposes by briquetting, though this considerably raises the price. Peat dried by exposure to the sun to a moisture content of 25—30% is very suitable for use in gas producers. The cost of producer gas installations is about equal to that of reciprocating steam engines; the cost of maintenance is only about one-half, while the economy has been shown in several cases to be 2—3 times as great; the heat losses in typical steam and gas plants given are :—

	Steam plant.	Gas plant.
Heat lost in ashes	2·00	1·10
,, ,, ,, radiation and cooling	4·60	18·60
,, ,, ,, smoke	24·60	—
,, ,, ,, radiation and friction	3·30	4·30
,, ,, ,, exhaust	53·50	23·70
,, ,, ,, jacket water	—	33·50
,, ,, ,, auxiliaries	7·30	—
Total losses in entire plant	95·30	81·20
Net efficiency of plant	4·70	18·80

—W. R. S.

Carbon; Latent heat of vaporisation of ——. C. Hering. Met. and Chem. Eng., 1914, **12**, 526—528.

The energy liberated when solid carbon combines wit gaseous oxygen: $C+O=26·1$ kilo.-cals., and $C+O_2=94·$ kilo.-cals., is represented by the difference between th chemical energy of combination and the physical energ required to render the carbon gaseous. Richards estimate the latter value at 45·7 kilo.-cals. By reducing this figur from 45·7 to 42·1 (about 9%), the equations are: $C+O = 26{\cdot}1 + 42{\cdot}1 = 68{\cdot}2$ (which is identical with $CO+O = 68{\cdot}2$), and $C+O_2 = 94{\cdot}3 + 42{\cdot}1 = 136{\cdot}4$, or $68{\cdot}2 \times 2$, kilo.-cals. It would thus appear that carbon develops exactly as much energy in combining with the first atom of oxygen as it does with the second.—W. R. S.

Gas; "New" or "double" —— for small works. C. B. Tully. J. Gas Lighting, 1914, **127**, 452—453.

"DOUBLE" gas is a mixture of coal-gas and water-gas having a calorific power from 380 to 400 B. Th. U., made by the gasification of coal and the generation of water-gas from the resulting coke in the same plant. The gas can be made in small gas-works (5 million cb. ft. per ann.) and sold more profitably at 2s. 6d. per 1000 cb. ft. than coal gas (550 B. Th. U.) at 6s. 3d. It is suitable for heating, and can compete with suction producer gas for gas engines. The plant consists of two gas producers connected at the lower part, each surmounted by a vertical retort chamber surrounded by chequer-brickwork. The producers are "blown" to incandescence for about 1 min. by an up-draught, and the hot gases burnt with a secondary air supply in the chequer-brickwork around the retorts, coal-gas passing from the retorts to the scrubber during this period. Steam is then passed downwards through the hot chequer-brickwork of one producer, then through the two producer chambers in series and upwards through the second retort chamber. During the next gas-making period, the direction of flow is reversed.—A. T. L.

Surface combustion. W. A. Bone. J. Roy. Soc. Arts, 1914, **62**, 787—796, 801—811, 818—827.

DESCRIPTIONS of the results obtained in the technical application of surface combustion have been given previously (see this J., 1909, 512; 1911, 527; 1912, 61, 524; 914, 303).—A. S.

Gas; Firing of —— by adiabatic compression. I. Photographic analysis of the flame. H. B Dixon, L. Bradshaw, and C. Campbell. *II. Ignition-points of mixtures containing electrolytic gas.* H. B. Dixon and J. M. Crofts. Chem. Soc. Trans., 1914, **105**, 2027—2053.

A DESCRIPTION of the experimental investigation, the chief results of which have been given previously (this J., 1914, 409). The ignition temperatures of different gases determined by the compression method were: $2H_2+O_2$, 526°; $2H_2+O_2+4H_2$, 602°; $2H_2+O_2+O_2$, 511°; $2H_2+O_2+7O_2$, 478°; $2H_2+O_2+N_2$, 537°; $2H_2+O_2+2N_2$, 549°; $2H_2+O_2+4N_2$, 571°; $2H_2+O_2+$ N_2, 615° C.—A. S.

Sulphur; Determination of —— in spent oxide. H. Marsden. J. Gas Lighting, 1914, **127**, 335.

THE usual errors in the carbon bisulphide method of estimation, due to the solubility of certain organic substances, may be avoided by treating the extract with strong sulphuric acid at steam-bath temperature. 5 grms. of the oxide are extracted as usual with carbon bisulphide, the extract being run into a weighed 250 c.c. flask. The latter with extract is dried in an oven and weighed, then heated with 10—20 c.c. of strong sulphuric acid on a steam-bath for about 4 hours, treated with about 200 c.c. of distilled water, and filtered. The residue is washed free from acid, dried and extracted with carbon bisulphide. The extract evaporated and the sulphur weighed. The difference in the weighings gives the amount of soluble organic matter.—W. F. F.

Petroleum; Production of —— in Canada, 1913. Oil, Paint, and Drug Rep., Aug. 31, 1914. [T.R.]

THE Department of Mines reports that the total output of petroleum in 1913 was 228,080 barrels, or 7,982,798 gallons, on which a bounty of $119,741.97 was paid. The total value of the production at the average price for the year $1.782 per barrel was $406,439. The total imports of petroleum oil, crude and refined, in 1913 were 22,779,293 gallons, valued at $13,230,429, in addition to ,628,837 pounds of wax and candles, valued at $108,897. The oil imports included crude oil 162,062,201 gallons, refined and illuminating oils 19,393,827 gallons, gasoline 29,525,170 gallons, lubricating oils 6,789,151 gallons. There was an increased importation in 1913 of all classes of oil with the exception of gasoline, the increases being most pronounced in crude oil and refined illuminating oil. There was comparatively little change in the production of natural gas in Ontario, but a large increase in the production in New Brunswick and Alberta. The total production in 1913 was approximately 20,345,000,000 feet, valued at $3,338,314 of which 828,000,000 feet was from New Brunswick; 12,487,000,000 feet from Ontario and 7,030,000,000 feet from Alberta.

Italian petroliferous zone; Importance of the ——. B. Galdi. L'Ind. Chimica, Min. e Metall., 1914, 1, 264—270.

THE petroleum industry in the province of Emilia has worked successfully with a moderate profit, and systematic prospecting for petroleum throughout the whole of Southern Italy is now recommended.—A. S.

Ceresin wax. E. J. Parry. Chem. and Drug., 1914, **85**, 376.

PARAFFIN waxes of different kinds have recently been adulterated with large amounts of rosin. The samples were sticky, showed uncertain m.pts., and had a taste of rosin. They gave the colour reactions for rosin, and had high acid and iodine values. Four samples gave:—Acid value, 48—60; saponif. value, 51—72·5; and iodine value, 40—56.—C. A. M.

Bagasse and molasses; Utilisation of ——. N. Deerr. *See* XVII.

Determination of carbon monoxide. Graham and Winmill. *See* XXIII.

Peat; Utilisation [excavation] of ——. T. Rigby, Dumfries, and Wetcarbonizing Ltd., London. Eng. Pat. 17,944, Aug. 6, 1913.

THE peat deposit is worked in relatively small, isolated portions, say of about 30 acres, separated by walls of peat of about 20 ft. thickness. When the peat is subsequently subjected to a heat treatment, *e.g.* wet carbonisation, the expressed water is returned to the excavations being worked. A worked-out excavation is used as a store from which water may be supplied to excavations being worked.—W. F. F.

Fuel; Process of manufacturing artificial —— from organic matter, e.g. peat. F. C. C. T. A. Osius, Grand Rapids, Mich. U.S. Pat. 1,105,206, July 28, 1914; date of appl., April 22, 1911.

THE organic matter, such as peat, is pressed to remove moisture, disintegrated, and treated with sulphuric acid until carbonised into a semi-plastic state. The acid may be removed by immersion in water, and the material moulded into briquettes.—W. F. F.

Briquettes and other articles; Manufacture of ——. C. M. Reynolds, Sparks, Nev. U.S. Pat. 1,103,078, July 14, 1914; date of appl., June 29, 1912.

WASTE wood is carbonised, the carbonaceous residue is mixed with a suitable binder, part of which consists of a portion of the tarry distillate, and the mixture briquetted. The briquettes are subsequently heated to a temperature sufficient to drive off the volatile portion of the binder and to harden them.—W. H. C.

Regulating combustion. G. W. Parker, New York, Assignor to The Parker-Russell Mining and Manufacturing Co., St. Louis, Mo. U.S. Pat. 1,104,000, July 21, 1914; date of appl., Dec. 9, 1909.

THE products of combustion from a deep bed of fuel are divided into a number of currents, air and steam being mixed with one of the currents in regulated proportions. This current is led by a circuitous path through the other currents, and the resulting heated gases are discharged into the bed of fuel.—W. F. F.

Combustion; Process of controlling ——. J. M. Rusby, Assignor to The United Gas Improvement Co., Philadelphia, Pa. U.S. Pat. 1,106,319, Aug. 4, 1914; date of appl., Feb. 13, 1911.

THE temperature effect of a fluid combustible is controlled by adding to the mixture of combustible and air definite proportions of the newly-formed products of combustion before the latter leave the combustion chamber.—W. H. C.

Inflammable gases; Means for detecting ——, *especially adapted for use in mines.* J. W. Manley, New Barnet, Herts., and W. J. L. Sandy, London. Eng. Pat. 18,166, Aug. 9, 1913.

THE catalytic substance used consists of a wire or plate of base metal coated with "granular palladium" prepared by mixing resin oil, oil of myrrh or oil of rosemary with palladium chloride, separating the resulting black precipitate and making it into a paste with oil of lavender. —W. E. F. P.

Mines; Detecting dangerous gases in ——. G. Schauli, Cheshunt, Herts. Eng. Pat. 14,498, Jan. 23, 1914.

AIR is drawn through pipes extending to various workings and tested for inflammable gases by ignition at a flame, the heat acting on a thermo-electric indicator. Heavy gases are indicated by passing the air through a balanced hollow chamber, the movement of which closes an electric-alarm circuit.—W. F. F.

Coke-ovens; Charging ——. H. Koppers, Essen-on-the-Ruhr, Germany, Assignor to H. Koppers Co., Chicago, Ill. U.S. Pat. 1,105,522, July 28, 1914; date of appl., Nov. 15, 1913.

To prepare a charge for a top-charged oven chamber, finely divided coal is dropped in, thus effecting a packing of the coal, and a loosening member is raised through the coal from the bottom of the chamber.—W. F. F.

[*Gas*]. *Retorts; Regenerator settings for vertical* ——. S. Glover, St. Helens, and J. West, Southport. Eng. Pat. 18,599, Aug. 15, 1913.

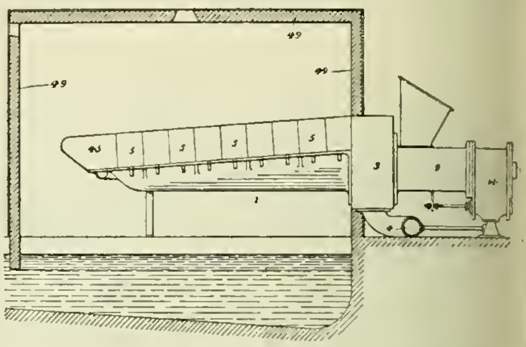
IN a regenerator setting of the type having independent combustion chambers around the retorts and additional chambers, around the lower ends of the retorts, for heating the secondary air, an independent supply of coal-gas is provided for each of the combustion chambers and the gas is preheated by being passed through coils disposed in the waste-gas flues and so arranged that they may be short-circuited when desired.—W. E. F. P.

[*Gas*] *Retorts; Discharging apparatus for vertical* ——. S. Glover, St. Helens, and J. West, Southport. Eng. Pat. 28,055, Dec. 5, 1913.

AT the lower end of the vertical retort one or more trays are provided to form a horizontal platform of adjustable size. The coke rests on this platform at its angle of repose, and a displacer in the shape of a sector of a cylinder is given a rocking motion about an axis in the plane of the platform, thereby causing the coke to fall from the edge of the platform without breakage and formation of "breeze."—W. F. F.

Gas producer. R. F. Boak, London. From C. F. Boak, Calcutta. Eng. Pat. 2578, July 22, 1913.

THE apparatus (see fig.) consists of a water-sealed chamber, 49, containing a horizontal "retort" or trough, 1, the upper part of which is formed by a series of hollow tuyère-blocks, 5: with the exception of the curved end-block, 45, each of the latter has a horizontal partition by means of which two parallel channels, one above the other, are formed within the series; and the lower part of each block has openings ("tuyères") communicating with the interior of the trough. Fuel is supplied to the latter from the chamber, 9, by means of a plunger or similar reciprocating device actuated from the cylinder, 14, of a steam engine; and around that end of the casing, 9, which adjoins the trough, an annular chamber, 3, is disposed, to which air, steam and exhaust gas (separately or together) are supplied by the pipe, 4. The annular chamber, 3, being in communication with the upper channel in the tuyère-blocks, the air, etc., from the former is preheated during its passage to the end-block, or chamber, 45, from which it passes to the lower channel and thence, through the tuyères, into contact with the fuel.—W. E. F. P.



Gas from liquid hydrocarbons; Means and methods of producing ——. W. Cameron, Warwick, and H. G. Burford, London. Eng. Pat. 17,241, July 28, 1913.

THE process consists in burning completely a small portion of the hydrocarbon with excess of air and then decomposing the remainder, together with the products of combustion, by contact with a bed of incandescent, refractory or carbonaceous material, the temperature of which is maintained by the incomplete combustion of a further small portion of the hydrocarbon.—W. E. F. P.

Gas from oil; Process of making ——. W. A. Hall New York. U.S. Pat. 1,105,772, Aug. 4, 1914; dat of appl., June 25, 1913.

A MIXTURE of water and oil is brought into contact with a mass of metallic nickel, containing a small proportior of cobalt, at 650°—750° C.—W. H. C.

Air-gas; Manufacture of ——. P. C. Pace, Billingshurst Sussex. Eng. Pat. 17,854, Aug. 5, 1913.

THE apparatus is of the type in which the air is supplie by a steam injector, the boiler is of the flash type, an the pressure of air and steam can be regulated. I starting, the gas-bell is drawn up to its highest point and supplies air-gas to the flash boiler, the compresse air from the injector passing through the carburetto which, together with the hydrocarbon tank, is situate within the gasometer. At the upper limit of its move ment, the bell opens a valve in the air-supply pipe or i may close the water supply to the boiler. In a modifica tion, the compressed air passes into the gasometer befor reaching the carburettor, which, together with the hydr carbon tank, is external to the gasometer.—W. F. F.

Combustible gases; Method and apparatus for produci ——. H. Strache, Vienna. Eng. Pat. 5730, March 1914. Under Int. Conv., Jan. 13, 1914.

IN an apparatus for continuously producing a mixture coal-gas and water-gas, the producer in the lower pa is charged with coke, and the distilling chamber or reto in the upper part with coal. Air is blown in under t grate, until the column of coke glows; the carbon mo oxide produced is burned in the space around the distilli chamber by blowing in additional air, and the produc of combustion escape to the chimney. During this period the gas-outlet valve of the distilling chamber is closed and coal-gas accumulates in the space above the coal, which is of relatively large dimensions, and gradually fills the chamber. During the subsequent steam blow, the gas-outlet valve is kept open until the coal-gas is completely displaced by the water-gas. The valve is then closed and the cycle of operations repeated.—W. E. F. P.

Gaseous fuel ; Production of ——. G. H. Benjamin, New York. U.S. Pat. 1,105,241, July 28, 1914 ; date of appl., Jan. 13, 1913.

A gas-producing material such as sawdust is distilled, and after separation of tar and ammonia by washing, the mixture of carbon monoxide and dioxide is passed through a zone of carbonaceous material strongly heated by an electric current, in order to reduce the dioxide to monoxide. This gas may be added to the "gas originally produced." —W. F. F.

Gas ; Purifying ——. C. J. O'Donnell and A. F. Kunberger, Philadelphia, Pa., Assignors to United Gas Improvement Co. U.S. Pat. 1,105,578, July 28, 1914 ; date of appl., April 18, 1913.

Gas is purified from carbon bisulphide by passing it through heated precipitated hydrated ferric oxide, or through ferric oxide heated to 400°—500° F. (204°—260° C.) —W. F. F.

Bituminous material ; Treating ——. J. C. Ross, Colorado Springs, Colo., Assignor to The Hydrocarbon Co. U.S. Pat. 1,104,140, July 21, 1914 ; date of appl., Sept. 27, 1911.

The bituminous material is mixed with a "suitable quantity" of litharge, the temperature being lowered and kept low, whilst the mixture is pulverised.—W. F. F.

Oil refining ; Apparatus for ——. J. R. Timmins, Assignor to O. Swain, Okmulgee, Okla. U.S. Pat. ,105,383, July 28, 1914 ; date of appl., April 10, 1913.

From the still, a valved pipe leads to the lower end of a primary condenser, and from the upper end of the latter a pipe leads to the lower end of a second condenser. A vapour pipe leads from the latter to a separator, and pipes from the second condenser and the separator lead to a cooling coil. A vapour-outlet pipe also leads from the separator to a cooling coil. A valved pipe leads from the first-mentioned cooling coil back to the still.—W. F. F.

Gasolene : Process of producing ——. J. W. Waitz, Oil City, Pa. : J. D. Trax and W. M. Parker, executors. U.S. Pat. 1,105,727, Aug. 4, 1914 ; date of appl., July 6, 1912.

Gasolene is obtained by compressing a suitable gas, cooling it, and then injecting it into a stratum of earth containing, or a well producing, fluid hydrocarbons. The saturated gas is recovered. and the hydrocarbon vapour condensed from it.—W. F. F.

Gasolene ; Manufacture of ——. W. M. Burton, Chicago, Ill., Assignor to Standard Oil Co., Whiting. Ind. U.S. Pat. 1,105,961, Aug. 4. 1914 ; date of appl., Aug. 25, 1913. Renewed May 25, 1914.

The liquid portions of the paraffin series of petroleum-distillation which boil above 500° F. (260° C.) are treated o obtain volatile products of the same series by distilling at 650°—850° F. (343°—454° C.). The distillate is condensed under a pressure of 4 to 5 atmospheres, and redistilled under atmospheric pressure. The final distillate s mixed with more of the original liquid, and subjected o the first-named treatment.—W. F. F.

Coking retorts : Vertical ——. J. Lütz, Bredeney, Germany. Eng. Pat. 17,887, Aug. 5, 1913. Under Int. Conv., Aug. 5, 1912.

See Ger. Pat. 263,767 of 1912 ; this J., 1913, 1058.—T. F. B.

Vertical retorts ; Regenerators for ——. S. Glover and J. West. Fr. Pat. 469,140, March 2, 1914. Under Int. Conv., Aug. 15, 1913.

See Eng. Pat. 18,599 of 1913 ; preceding.—T. F. B.

Gas for lighting and heating purposes ; Process for the production of ——. L. Vignon, Lyon, France. Eng. Pat. 29,624, Dec. 23, 1913. Under Int. Conv., Jan. 2, 1913.

IIb.—DESTRUCTIVE DISTILLATION ; HEATING ; LIGHTING.

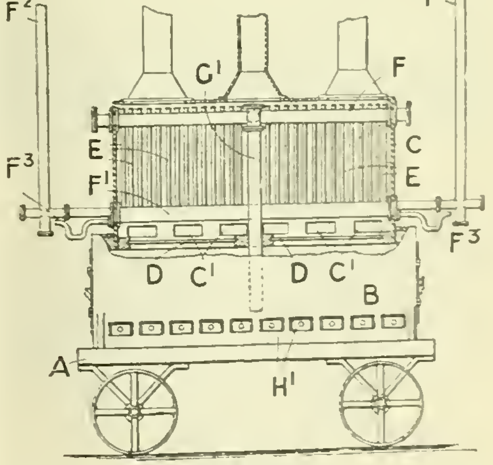
Patents.

Peat ; Treatment of ——. T. Rigby and G. W. Andrew, Dumfries, and Wetcarbonizing Ltd., London. Eng. Pat. 9392, April 21, 1913.

To facilitate the removal of water in the heat treatment of wet peat (heating and pressing), cutting or grinding of the fibres is avoided as far as possible. The hot effluent from peat, pressed at about 100° C., is passed into and through fresh peat for economy.—W. F. F.

[Wood] Distillation apparatus ; Retorts or ——. H. Sykes, Bideford, Devon. Eng. Pat. 17,722, Aug. 1, 1913.

The condenser, C, is superposed upon the retort chamber, B, and comprises a number of tubes, E, the ends of which open into headers, F, F¹. The upper header is connected by pipes, G¹, with the interior of the retort chamber, while the lower header collects the products of distillation, which are removed by pipes, F³. Pipes, F², extending upwards, are connected with the lower header to induce draught through the openings, H¹, which can be controlled, and through the retort chamber and condenser tubes, whilst



orifices, C^1, which can also be controlled, are provided to induce draught through the condenser casing. The material to be treated (*e.g.*, wood, etc.) is packed between the casing and tubes for preliminary heating, and is fed to the retort by opening the slides, D. The whole apparatus is mounted upon a wheeled carriage, A.—W. F. F.

Peat; Treatment of ——. T Rigby, Dumfries, and Wetcarbonizing, Ltd., London. Eng. Pats. (A) 11,133, May 10, 1913, and (B) 18,030 of 1914; date of appl., May 10, 1913.

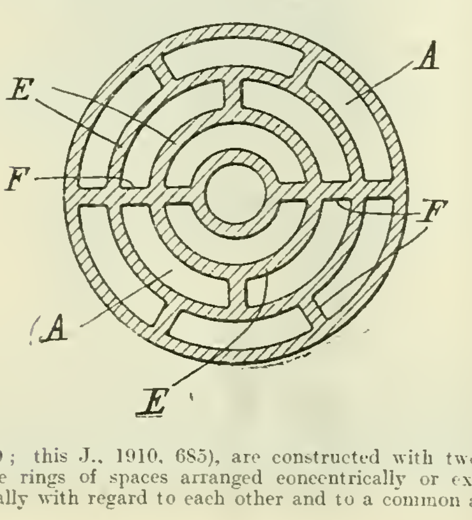
(A.) Peat as wet pulp is passed continuously through a heating apparatus in which it is heated sufficiently to destroy its water-binding properties (*e.g.*, to about 100° C. See Eng. Pats. 5873 and 9392 of 1913; this J., 1914, 783 and preceding), without evaporation of the water; when it has been heated sufficiently to render the water easily expressible, the heat of the treated mass is transferred to fresh material entering the heating system. The hot peat may be removed to a space in which a lower pressure prevails than that corresponding to the vapour tension of steam at that temperature, and the steam thus produced is passed over fresh peat. In another method, a current of gas is circulated between two vessels containing the hot treated peat or liquid expressed from it and the fresh peat. (B.) Peat which has been wet-carbonised or otherwise heat treated, to render its water more easily removable, is filter-pressed at a high temperature (60° C. or above) and the hot effluent so obtained is mixed with raw peat awaiting treatment. (Reference is directed, in pursuance of Sect. 7, Sub-sect. 4, of the Patents and Designs Act, 1907, to Eng. Pat. 1046 of 1911.)—T. F. B.

Wood; Distillation of ——. W. Danner, Slidell, La., Assignor to Forest Products Co. U.S. Pat. 1,096,687, May 12, 1914; date of appl., Sept. 6, 1912.

The ovens are disposed in pairs and are operated alternately. When the charged retort has been placed in position in the oven, live steam is injected, volatile products such as turpentine are driven off, and rosin is run off. The second retort of the pair is now treated in this way, and superheated steam admitted into the first retort to drive off heavier vapours. The first retort is withdrawn and replaced by another, and then superheated steam admitted to the second retort, this cycle of operations being repeated as desired.—W. F. F.

Retorts for the distillation, carbonisation, and the like of coal and other carbonaceous materials; Construction of ——. C. W. Tozer, London. Eng. Pat. 7116, March 20, 1914.

Retorts in which distillation or carbonisation is effected in a number of chambers of approximately the same size, grouped round a central axis (see Eng. Pat. 20,158 of 1909; this J., 1910, 685), are constructed with two or more rings of spaces arranged concentrically or eccentrically with regard to each other and to a common axis, all the spaces having approximately the same cross-sectional area. A retort with three such rings of spaces is shown in cross-section in the figure. The spaces, AA, are formed by the walls, EE, and the ribs, FF, which are tapered so as to facilitate charging and discharging. Passages may be provided in some of the ribs through which heating gases are introduced from the furnace to the central passage. One retort with twelve chambers capable of holding half a ton in all, will carbonise that quantity in about one-twentieth of the time necessary when using a plain tubular retort of equivalent diameter. —T. F. B.

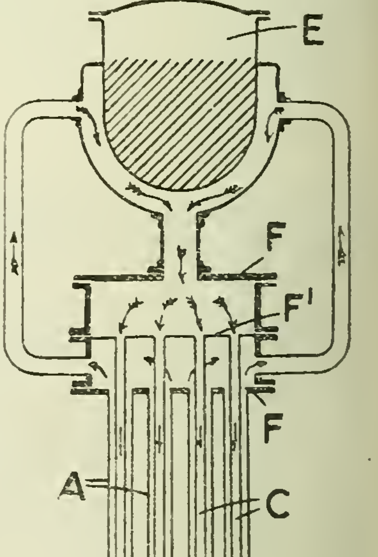


Oils and other products from carbonaceous matter or other materials containing hydrocarbons; Method of and apparatus for obtaining ——. W. G. Wilson, Farningham. Eng. Pats. 18,406, Aug. 13, 1913, and 2428, Jan. 29, 1914.

Shale or other substance to be treated is introduced into a vertical or inclined chamber, in which combustion and distillation are maintained by introducing continuously a relatively large amount of the distillation gases below th combustion zone; a relatively small quantity of air is als admitted, either intermittently or continuously, at th same point, and steam may also be introduced if desired The distillation gases are passed through a condenser an then freed from the last traces of condensable products b mechanical separation, preferably in a circulating fan o pump which forces the gases into the heating chamber a pipe is provided in the casing or compression chambe of the fan or pump, through which the condensate is ru off. A suitable hopper is attached to the heating chambe to enable the material to be introduced without admittin air, and the bottom of the chamber is provided with water seal or arrangement of sliding valves to enable th spent material to be removed without allowing air to ente —T. F. B.

Oil-baths, and means for heating liquid therefor. E. I Higgins, Wallasey, Cheshire. Eng. Pats. (A) 17,190 1914, date of appl., July 28, 1913, and (B) 17,334, July 2 1913.

(A). The bath is jacketed and is heated by oil circulat through the jacket and through a separate heating devic



The latter consists of a number of thermal siphons or l tubes, the outer and inner tubes of which are conne espectively with the upper and lower parts of the jacket. s). The apparatus is similar in principle to the preceding. The outer tubes, A (see fig.), of the Field tube units are arried by the casing of a reservoir, F, while the inner tubes, , are carried by the partition, F^1, which divides the reser-oir into two compartments for the hot and cold oil. The irculation of oil round the jacketed receptacle, E, is shown y the arrows. The reservoir, F, may be dispensed with, he tubes, A, being connected with the wall of the jacket, nd the inner tubes, C, with a partition which divides the acket into two concentric annular chambers.—W. F. F.

hale ; Retorts for the distillation of ——. J. W. Fell, Sydney, N.S.W. Eng. Pat. 12,254, May 18, 1914. Under Int. Conv., March 30, 1914.

CAST iron retort for shale distillation is made slightly apering and in sections, the top of each section being nlarged to form an annular space in conjunction with the ottom of the section next above it ; flues or passages re provided in the enlargements in each section, through hich the products of distillation pass to the vertical nain.—T. F. B.

amps ; Electric incandescent ——. The British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, U.S.A. Eng. Pat. 18,447, Aug. 13, 1913.

. TUNGSTEN filament lamp is provided with a "getter" ich as potassium thallium chloride, contained in a small pen tube (see Eng. Pat. 14,048 of 1913), and after exhaus-on a gas, preferably nitrogen, is admitted up to a pressure f 10 to 50 microns. An improved efficiency and longer fe is thereby obtained.—W. F. F.

rc lamps ; Carbon electrodes for electric ——. C. Conradty, Nürnberg, Germany. Eng. Pat. 22,223, Oct. 2, 1913. Under Int. Conv., July 2, 1913.

o improve the adhesion of chemical coatings to carbon ectrodes, the surface of the carbon is roughened and ndered porous by the removal of the outer skin after haping.—W. F. F.

III.—TAR AND TAR PRODUCTS.

olycyclic hydrocarbons ; Hydrogenation of —— *by sodammonium. Preparation of the tetrahydro-derivatives of naphthalene and acenaphthene, and dihydro-anthracene.* P. Lebeau and M. Picon. J. Pharm. Chim., 1914, **10**, 97—100.

HE tetrahydronaphthalene produced by treating a ixture of naphthalene and sodium with liquid ammonia his J., 1914, 637) is the 1.2.3.4-derivative. Acenaphthene, nder like conditions, furnishes a tetrahydro-derivative, oiling at 251° C., and anthracene yields dihydro-anthra-ene (b.pt. 313° C.).—F. Sodn.

nthracene derivatives ; The sensitiveness of —— *to light. I. Anthracenecarboxylic acids.* F. Weigert and L. Kummerer. Ber., 1914, **47**, 898—908.

HE three anthracenecarboxylic acids undergo a reversible olymerisation under the influence of light, and in the bsence of oxygen. The reaction is most conveniently rought about by exposing the acids in solution in acetic cid, toluene, or alcohol to the light of a mercury vapour mp for from one to eight hours, the solution being con-tined in a specially devised vessel, and allowed to boil under the influence of the lamp. On cooling, the products crystallise out. They are dimeric forms of the original acids, and depolymerisation occurs at the same temperatures as those of their formation, thus demonstrating the reversibility and energy-storing nature of the photochemical action. The *photo*-acids are all white substances and do not give the fluorescence with ammonia characteristic of the original acids. They do not melt sharply, owing to partial depolymerisation occurring at a lower temperature. In presence of oxygen the photo-chemical action results also in the formation of anthraquinone which, if an aqueous solution of the sodium anthracenecarboxylate is used, separates out after a very short exposure. In absence of oxygen, even in aqueous solution polymerisation occurs exclusively and this provides the first instance of an energy-storing photo-chemical action in homogeneous aqueous solution.—G. F. M.

The European war and U.S. chemical industries. See IV.

Patents.

4-*Chloro*-1-[*hydr*]*oxyanthraquinone and its derivatives ; Manufacture of* ——. F. Ullmann, Charlottenburg, Germany. Eng. Pat. 15,058, June 23, 1914. Under Int. Conv., Dec. 22, 1913.

1-Hydroxyanthraquinone or a derivative thereof is treated with sulphuryl chloride, in presence of nitrobenzene or other solvent, and with or without the addition of iodine or other catalyst. The chlorine atom enters the *para*-position with respect to the hydroxyl group, 4-chloro-1-hydroxyanthraquinone or a derivative thereof being produced. By further action of sulphuryl chloride in presence of a catalyst, polychloro derivatives are obtained.—T. F. B.

Pitch and tar ; Process and apparatus for treating ——. H. W. Robinson. Fr. Pat. 468,320, Feb. 11, 1914. Under Int. Conv., Feb. 18 and April 30, 1913.

See Eng. Pats. 4159 and 10,156 of 1913 ; this J., 1914, 412.—T. F. B.

IV.—COLOURING MATTERS AND DYES.

Fusarium ; The colouring matters of ——. Bezssonoff. Comptes rend., 1914, **159**, 448—450.

A red and a yellow colouring matter were isolated from the fungus *Fusarium orobanchus.* The former had the properties of a carotine ; it crystallised in tablets and yielded different coloured solutions when dissolved in various solvents. The absorption bands exhibited by these solutions (violet in chloroform, red-violet in benzene, and yellow in cumene after boiling) showed a gradual displacement in the order given. The yellow colouring matter was crystallised from its aqueous solution ; it acted as a feeble acid and was always accompanied by sugar.—W. P. S.

U.S. imports of dyestuffs. Oil, Paint, and Drug Rep., Aug. 31, 1914. [T.R.]

The American situation in dyestuffs is still acute. The authorities at Washington have tried to make arrangements for importing these materials from Germany, but without success. It is stated that other countries will not require the stocks now held in Germany, and if means can be found to transport them to this country the textile mills here will be enabled to operate for another year. Otherwise many of the cotton, wool, and silk mills will be forced to close in sixty days.

The European war and U.S. chemical industries. Metall. and Chem. Eng., Sept. 1914, 551.

"Metallurgical and Chemical Engineering" has asked a few men, prominent in American chemistry, the following questions :—

1. How does the cutting-off of the supply of certain raw materials by the European war affect the continuity of operation of the various chemical industries in this country ? Can any of these raw materials be procured in

the United States so as to make our industries independent of other countries? What is the situation of the potash industry?

2. Will the forced industrial restriction in Europe, if it continues long enough, warrant the development in this country of chemical industries which have so far been almost exclusively European? What are the possibilities of an American coal tar industry?

3. In the case of a long continued war, do you think that the personnel of the American chemical and metallurgical industries will be affected? Do you think it possible that there may be a scarcity of chemically trained men or of unskilled workmen?

4. Is there enough demand in South American countries for products of the chemical industries to make exports from this country worth while and open new markets for the chemical industries of this country?

In reply Dr. W. H. Nichols stated:—

1. The supply of raw materials for heavy chemicals called for little uneasiness. Stassfurt potash salts being entirely cut off, the farmer might have to do without them, but substitutes would take their place. Potash for other industries might be secured from sea weed or felspar.

2. The prospects of the American coal tar industry would depend on the encouragement which the buyer gave to the manufacturer. The experience of the Benzol Products Co., which started in a small way to manufacture aniline oil, was that although a tariff of 10% was placed on aniline oil by Congress, foreign manufacturers reduced the price to a point where it was impossible to compete.

4. The South American market for chemicals was an important one, and though not yet developed, might grow into an outlet for American products. The difficulties of doing business in South America had been caused by lack of banking facilities. All U.S. copper mines had reduced production by 50% and the refineries had followed suit. As one-half of the copper produced had heretofore gone abroad, this curtailment should provide for all local requirements.

Interviews on the coal-tar industry.—Mr. William J. Matheson commented on question (2) as follows:—

In regard to intermediate products, such as aniline oil, aniline salts, beta-naphthol, paranitraniline, etc., the industry is already developed, and its growth depends in large measure upon the supply of cheap benzol.

Dr. B. C. Hesse commented on question (2), and divided coal-tar products into—

I. Products from coal-tar by distillation, expression and like operations.

II. Products obtained from I. by chemical transformation but not themselves dyes.

III. Dyes made from II.

Germany's foreign trade in 1913 in these three classes was as follows (in metric tons):—

	Imports into Germany.	Exports from Germany.	Excess of exports over imports.
I.	67,501	342,893	275,392
II.	673	16,311	15,638
III.	3,238	163,874	160,636

Division II. included aniline oil and salt, naphthol an naphthylamine, anthraquinone, nitrobenzol, toluidin resorcinol, and phthalic acid.

Division III. included aniline dyes, anthracene dye other than alizarin red, alizarin red, and indigo.

At present the United States produced about 30% its requirements of aniline dyes (Division III.), but almo entirely from materials of Division II. brought fro Germany.

In Division II. Germany controlled the world's market This control was due to the field becoming much inte woven, each of its hundred or more products being depe dent upon or made up of one or more other products, one of which was of use without others. Not one of t 22 factories in Germany was independent of other factori in Germany, whereas together they were independent sources outside Germany. It would not do merely transplant even the largest German works to this countr a part of each German works would be necessary to p duce anywhere a complete and self-contained industry.

Except Switzerland, no country had succeeded selling to Germany more coal-tar dyes than it bought fr Germany, but all of them bought more of intermedia products from Germany than they sold Germany.

German exports of tar products and dyestuffs were follows (in metric tons):—

	Division II.			Division III.				Net totals.
	a	b	c	d	e	f	g	
	Aniline oil.	Naphthol and naphthylamine.	Anthraquinone, etc.	Aniline dyes.	Varicoloured alizarins.	Alizarin red.	Indigo.

No. of countries Germany exported to	11	6	11	32	12	9	21	

The number of coal-tar dyestuff works was as foll 22 Germany, 11 France, 11 Great Britain, 9 United St 4 Austria-Hungary, 4 Switzerland, 2 Holland, 2 Ru 1 Belgium, 1 Greece, 1 Italy. Sixteen plants that coal-tar dyes had abandoned it, 11 in Germany, and each in Austria, Belgium, France, Great Britain Switzerland. Fourteen had been absorbed by ot six in Germany, four in Switzerland, two in France, one each in Belgium and Holland.

A complete coal-tar dye industry in America would to make about 700 different dyes. In the fiscal 1913—1914 America imported indigo worth $1,093 alizarin $845,459, both free; $7,464,134 worth of a dyes with a duty of 30% and aniline oil with a du 10%. These 700 different aniline dyes would aver gross annual income each of about $10,000. To intr 700 different sets of operations and perhaps 350 diff sets of apparatus at *one time* to produce on the av for each set of operations a gross of $35 per day require an initial outlay of $5,000,000. Eac these 700 products required good manufacture fro start because good qualities of each were already on the market. It was one thing to develop such an industry and to maintain it against newcomers, but another to build it up in the face of competition and to hold it against those who developed the business, knew all its ins and outs, had their experience and plant bought, paid for, and written off long ago. It could hardly be expected that if successful this would employ as many as 7000 people, and the gross made out less than 0·4% of the total import business.

This industry could not be successfully transplanted and attempts to transplant part only had not resulted in any self-contained and independent industry anywhere but in a thing whose roots were still in German soil. If it could be transplanted as a whole the net result would not be commensurate with the expense, effort and risk connected with it.

Dr. L. J. Matos said that the question was primarily, whether they produced enough coal tar to make them independent of any foreign source of tar, and also whether higher prices could be obtained for certain tar distillates than the colour industry could afford to pay.

It was not so much a question of inability of chemists to produce dyes, but of the *temporary handicap of not having the especially designed and constructed appliances* for the proper conduct of the technical operations in elaborating the several raw materials to middle and ultimate products.

Tar products, dyestuffs, and hydrochloric acid, etc.: German prohibition of export of ——. Consular Repts. No. 115. [T.R.]

The British Consul-General at Rotterdam reports that the *Reichsanzeiger*, Berlin, of September 15th contains a decree prohibiting the export of hydrochloric acid, dyestuffs, and all materials used in the manufacture of explosives, as well as coal-tar dyes, tar, and other products of the chemical industry, except benzoic acid.

Patents.

Azo-dyestuffs from the arylides of 2.3-hydroxynaphthoic acid; Manufacture of ——. A. G. Bloxam, London. From Chem. Fabr. Griesheim Elektron, Frankfort a/M., Germany. Eng. Pat. 10,085, April 23, 1914.

The arylides of 2.3-hydroxynaphthoic acid are combined with diazo- or tetrazo-compounds of the anthraquinone series to form red lake colours, fast to oil, or the combination may be effected on the fibre to give dyeings which are faster than the corresponding ones from β-naphthol. Cotton padded with the anilide of 2.3-hydroxynaphthoic acid and developed with the diazo-compound of 1-aminoanthraquinone is dyed a brilliant red, fast to soap and light.—J. B.

Vat dyestuffs; Process for making ——. Farbwerke vorm. Meister, Lucius, und Brüning. Second Addition, dated Jan. 26, 1914, to Fr. Pat. 447,592, Aug. 23, 1912. Under Int. Conv., June 11, Sept. 18, Oct. 6 and 13, 1913.

See Eng. Pat. 3682 of 1914; this J., 1914, 743.—T. F. B.

Polyazo dyestuffs; Process for producing blue ——. L. Cassella und Co. G. m. b. H. Fr. Pat. 468,065, April 11, 1913.

See Eng. Pat. 17,030 of 1913; this J., 1914, 743.—T. F. B.

Azo dyestuff which can be developed on the fibre; Process for making an ——. Kalle und Co. A.-G. Fr. Pat. 468,902, Feb. 25, 1914.

See Ger. Pat. 275,660 of 1912; this J., 1914, 828.—T.F.B.

Anthraquinone series; Process for preparing sulphurised products of the ——. Chem. Fabr. Griesheim-Elektron. Fr. Pat. 468,373, Feb. 12, 1914. Under Int. Conv., June 4, 1913.

See Ger. Pat. 271,947 of 1913; this J., 1914, 545.—T. F. B.

Patent Case.

Black colouring matter directly dyeing cotton; Manufacture of a ——. C. D. Abel, London. From the Actiengesellschaft für Anilinfabrikation, Berlin, Germany. Eng. Pat. 1151 of 1900; this J., 1900, 1010. Reports of Patent Cases, Vol. XXXI. Illus. Off. Jnl. (Patents) Suppl., May 6, 1914. By permission.

This was an action for infringement brought by the patentees against Levinstein, Ltd. One of the claims in the patent was for the manufacture of the colouring matter by boiling meta-dinitrophenol 1 : 2 : 4 with an aqueous solution of sulphur and a sulphide of an alkali metal. The defendants alleged (*inter alia*) that the patent was invalid for want of subject matter by reason of a prior specification of Cassella (Eng. Pat. 19,831 of 1896; this J., 1897, 734), and for insufficiency of the specification. They contended that if a wide construction was put upon the specification and the patent was for a boiling process, instead of a melting one as in Cassella's specification, there was no sufficient subject matter; that the plaintiffs' specification did not sufficiently define the limits of variation; and that the defendant's process differed from the patented process in the fact that in it not meta-dinitrophenol 1 : 2 : 4 but a sodium salt thereof was used. The plaintiffs contended that their specification ought to be widely construed and that the sodium salt was an equivalent of meta-dinitrophenol. The Court held, that a narrow construction must be put on the specification; that the substitution of a comparatively long boiling process for the comparatively short melting process of Cassella was of great commercial importance, and that the patent was not wanting in subject matter; that the patent was not invalid by reason of the limits of variation not being defined; but that the sodium salt was not a known chemical equivalent of meta-dinitrophenol; and the patent had not been infringed. The action was dismissed.

V.—FIBRES; TEXTILES; CELLULOSE; PAPER.

Plastic materials [artificial silk, etc.]. Recovery of volatile solvents used in the manufacture of ——. H. Barthélemy. Les Matières Grasses, 1914, 7, 4208—4213.

The absorption capacity of sulphuric acid for ether is a function of its sp. gr. From air containing only a few parts of ether per 1000 (as in artificial silk factories), sulphuric acid of 66° B. (sp. gr. 1·84) will absorb only about one mol. of ether, and acid containing one or more mols. of water will absorb little or none. An equimolecular mixture of ether and strong sulphuric acid is deprived of its ether by passage of a current of moist air, after sufficient hydration of the acid (compare Fr. Pat. 350,298 of 1905; this J., 1906, 71, 925). Of other volatile solvents carbon bisulphide could be absorbed as potassium xanthate by alcoholic potassium hydroxide, or by alkali-cellulose for conversion into viscose; whilst toluene (or benzene) vapours might be absorbed by hot concentrated sulphuric acid or by sulpho-nitric acid, to obtain toluenesulphonic acid or *p*-nitrotoluene.—C. A. M.

Wood pulp and cellulose: Withdrawal of German prohibition of export of ——. Consular Reports. No. 115. [T.R.]

The British Consul-General at Rotterdam reports that the *Reichsanzeiger*, Berlin, of September 15th contains a proclamation cancelling the prohibition of exports and transit of mechanical and chemical wood pulp and cellulose.

Patents.

Fibrous and like materials [wool]; Apparatus for drying ——. G. Stone, North Andover, Mass., U.S.A. Eng. Pat. 201, Jan. 3, 1914.

Heated air is forced through a conduit having side-branches each terminating in a valve-controlled orifice pointing upwards. Over each orifice is fitted a vertical perforated pipe fixed into the centre of the base of a stage and keeping the valve open by depressing a pin so long as it remains in position. The material is built up on the stage around the central pipe and the whole supported by a bag or other porous envelope. The stage is suspended by means of frame standards to a counter-balancing lever, the weight on which is so adjusted that when the material has dried to a sufficient degree the frame and stage are lifted off the hot air orifice over which they fit, at the same time releasing the valve so as to close the orifice.—J. F. B.

Animal wool; Process of making substitutes for ——. C. Chavez, Mexico City. U.S. Pat. 1,104,105, July 21, 1914; date of appl., May 20, 1913.

WASTE fibre is steeped in water and submerged successively in baths of caustic soda at 1·027 sp. gr., bleaching powder solution at 1·041 sp. gr., and sulphuric acid and sodium bisulphite at 1·034 sp. gr., remaining in each bath for 3—4 hours. The material is then treated in a boiling "basic" bath of sulphuric acid and sodium bisulphite at 1·02 sp. gr., then in cold caustic soda at 1·152 sp. gr. for mercerisation; lastly it is again treated with bleach liquor at 1·041 sp. gr. and finished with sulphuric acid and sodium bisulphite at 1·02 sp. gr.—J. F. B.

Cellulose esters of organic acids; Process for preparing ——. Knoll und Co. Ger. Pat. 275,962, July 15, 1911.

To effect a regular and systematic reaction of cellulose with organic acids, the esterifying agent is circulated through a series of vessels containing cellulose in various stages of esterification, in such a manner that it comes in contact in successive vessels with cellulose in a lower state of esterification. A diluent in which the resulting ester is insoluble, may be added to the esterifying agent, and the presence of a catalyst is advantageous.—T. F. B.

Acetylcellulose solutions; Production of white or coloured opaque objects from primary ——. Knoll und Co. Ger. Pat. 276,013, Nov. 14, 1912.

AN aromatic acid, ester, or ether which does not dissolve or decompose acetylcellulose (phthalic acid, ethyl, methyl, or β-naphthyl benzoate, benzyl chloride, anisol, etc.), is added to a solution of acetylcellulose in acetic acid, or to the mixture before acetylation. The resulting mixture is heated for a short time until a clear solution is obtained, and this is precipitated in the usual manner by means of water, salt solutions, etc., to form stable, white, opaque filaments or other objects. Coloured opaque products may be obtained by adding suitable dyestuffs to the solution.—T. F. B.

Paper pulp; Machines for straining ——. W. W. Beaumont, London. Eng. Pat. 17,552, July 31, 1913.

IN the type of strainer consisting of a rotating and vibrating drum partly immersed in the pulp, which passes upwards from the outside through the slits and is discharged from the ends of the drum (see Eng. Pat. 23,191 of 1912), the open ends of the drum are provided with flanges, faces or grooves, forming a joint with similar arrangements on the ends of the vat, the joint being packed with flexible or adjustable metal or "woodite" rings kept in position by pneumatic or other extensible rubber filling, or by a spring or tension device or a metal spiral band which may be filled with felt.—J. F. B.

Bleaching lignocellulose and pectocellulose; Process for ——. A. R. de Vains, Paris. U.S. Pat. 1,106,994, Aug. 11, 1914; date of appl., Aug. 18, 1913.

SEE Fr. Pat. 449,497 of 1912; this J., 1913, 482.—T. F. B.

Beating engines for the manufacture of paper and similar purposes. R. Marx. Fr. Pat. 469,011, Feb. 27, 1914. Under Int. Conv., April 17, 1913.

SEE Eng. Pat. 9049 of 1913; this J., 1914, 20.—T. F. B.

Treatment of seaweeds. U.S. Pat. 1,103,283. *See* VII.

Composition [for varnish] containing sulphite waste and shellac. U.S. Pat. 1,103,267. *See* XIII.

Manufacture of syrup and other products from alfalfa. U.S. Pats. 1,104,135 and 1,104,136. *See* XVII.

Apparatus for separating solid matter, more particularly fibrous matter, from liquids such as waste water. Eng. Pat. 6793. *See* XIXB.

Protecting clothing, furs, skins, etc., against moths, beetles, and insects. Eng. Pat. 10,379. *See* XIXB.

VI.—BLEACHING; DYEING; PRINTING; FINISHING.

Silk; Cause and prevention of the defect in piece-dyed fabrics supposed to be due to a splitting of the fibre of ——. B. Leech. J. Soc. Dyers and Col., 1914, 30, 272—277.

THE defect known as soap-mark, break-mark, chafe-mark, fiochetti, lousiness (American), etc., is shown to be due to a mechanical scarring of the fibre, the resulting particles and minute fibrillæ giving the optical effect of a lighter shade owing to their broken surface. Mechanical injury is the cause of the defect and may occur through adhesion during degumming and through friction during dyeing, degumming, or other treatment of the wet goods. The trouble is most frequent in goods which offer the greatest opportunities for mechanical strains during dyeing, etc., *i.e.* spun silk woven in unions with a harder fibre, or even thrown silk in heavy cloths or when woven with a harder fibre. Skein silk also sometimes shows the marks when the thread is very thick or stiff. The defect is avoided by handling the goods as little as possible, for which purpose the cloth is pinned out in separate folds on a rigid frame for immersion in dye-baths, etc. —J. B.

Sodium sulphide; Rapid determination of —— in a standing sulphide dye-bath. R. N. Len. J. Soc. Dyers and Col., 1914, 30, 277—278.

THE sodium carbonate is removed by means of barium chloride and the dyestuff is precipitated by adding an excess of sodium chloride. After settling, the sodium sulphide is titrated with zinc sulphate using sodium nitroprusside as an external indicator. If sodium chlorid does not clear the solution sufficiently a little pure cotto may be added. The method was tested on dyebath made up from Kryogen Yellow GG., Kryogen Violet 3R. Kryogen Direct Blue G. and Katigen Brilliant Green G. and except in the case of the violet was found to give sharp end-point.—J. B.

PATENTS.

Bleaching; Washing apparatus used in ——. W M'Murray and T. Knowles, Lambeg, Ireland. Eng Pat. 17,971, Aug. 7, 1913.

A MACHINE for washing in rope form consisting of a numbe of adjacent boxes, having separate water inlets an outlets, through which the cloth passes in successio A squeezing roller runs over the set of boxes and th cloth preferably enters the apparatus at opposite end and is taken off at the middle.—J. B.

Yarns, slubbings, rovings and slivers; Cleaning, washin and otherwise treating textiles in the form of ——. F. Larivei, Milan, Italy. Eng. Pat. 26,073, Nov. 13, 191

THE material travels between pairs of corrugated rolle so arranged that the peaks of the corrugations con opposite one another. The upper rollers are mount on a frame which can be moved to adjust the distance between the rollers. An automatic reversing gear is used.—J. B.

Dyeing machines. C. Callebant and J. de Blicquy, Brussels. Eng. Pat. 24,721, Oct. 30, 1913.

Cylindrical receptacles of inert material (*e.g.* earthenware), which hold the material to be dyed, have perforated false bottoms and perforated covers. The cylinders rest in seatings at the bottom of the dye-vat, through which they are in communication with the circulating pump. —J. B.

Dyeing; Method of ——. H. C. Brook, Hartford, Conn. U.S. Pat. 1,096,997, May 19, 1914; date of appl., Sept. 30, 1913.

Material in the form of piece-goods is doubled longitudinally and joined together at the selvedges to form a tube; the two ends are joined and the endless tubular belt is passed between a pair of pressing rolls situated above the dye-bath so that the lower portion of the fabric hangs freely in the liquor. The fabric is guided into and out of the press by two guide-rolls as it moves forward; the air imprisoned in the tube "balloons" the fabric as it passes through and out of the liquor, thus smoothing out all wrinkles by a gentle tension during its treatment with the dye-liquor.—J. F. B.

Fabrics; Decoration of ——. Winsor and Newton, Ltd., and H. Emens, London. Eng. Pat. 21,160, Sept. 19, 1913.

The threads, constituting the design of the fabric, are first impregnated with a liquid which reduces the porosity, such as a solution of wax in a hydrocarbon or a chloro-derivative of a hydrocarbon, and then, when dry, with one or more colouring fluids, *e.g.*, with a finely sub-divided pigment incorporated with a thickened drying oil, or an artist's water colour or dyestuff incorporated with an aqueous solution of gelatin.—B. N.

Printing machines for textiles, paper or other fabrics. Elsässische Maschinenbau-Ges., Mülhausen, Germany. Eng. Pat. 28,503, Dec. 10, 1913. Under Int. Conv., March 15, 1913.

In machines for printing in intaglio in which a small, yielding impression roller is interposed between the engraved roller and the pressure roller, the latter is replaced by a pair of pressure rollers of larger diameter than the impression roller, which is disposed between them in such a way as to prevent lateral deflection.—J. B.

Dyeings on the fibre; Producing fast ——. R. Herz, Frankfort, Germany, Assignor to Cassella Color Co., New York. U.S. Pat. 1,107,164, Aug. 11, 1914; date of appl., Feb. 21, 1913.

See Eng. Pat. 25,897 of 1912; this J., 1913, 1007.—T.F.B.

Dyeing apparatus. A. R. Whitehead and J. Farrar. Fr. Pat. 468,713, Feb. 12, 1914.

See Eng. Pat. 28,245 of 1912; this J., 1914, 20.—T. F. B.

Prints and colours; Production of fast ——. H. Levinstein, and Levinstein, Ltd. Fr. Pat. 468,246, Feb. 9, 1914. Under Int. Conv., Feb. 10 and 20, 1913.

See Eng. Pats. 3427 and 4316 of 1913; this J., 1914, 309, 350.—T. F. B.

Prints on fabrics; Process for obtaining fast —— by means of dyestuffs applied by reduction. K. Gross. Fr. Pat. 468,762, Feb. 20, 1914. Under Int. Conv., Feb. 27 and Sept. 2, 1913.

See Ger. Pats. 272,526 and 272,527 of 1913; this J., 1914, 547.—T. F. B.

Bleaching solutions containing titanous chloride and method of producing the same. U.S. Pat. 1,105,308. *See* VII.

VII.—ACIDS; ALKALIS; SALTS; NON-METALLIC ELEMENTS.

Sulphurous acid; Volumetric method for the determination of ——. G. S. Jamieson. Amer. J. Sci., 1914, 38, 166—168.

Sulphurous acid is titrated with potassium iodate in the presence of 15—20% HCl and a small volume of an immiscible solvent such as chloroform, the solution being cooled to 15°—18° C. The potassium iodate is standardised with pure, resublimed iodine, and the end point in each case is indicated by the disappearance of the violet coloration of the chloroform. The equations are: $KIO_3+2H_2SO_3+2HCl=2H_2SO_4+ICl+KCl+H_2O$; and $4I+KIO_3+6HCl=KCl+5ICl+3H_2O$.—O. R.

Sodium bichromate; Manufacture of ——. G. Ulm. Chem.-Zeit., 1914, 38, 670.

Chrome iron ore, quicklime, and a portion of the necessary sodium carbonate, are finely ground, thoroughly mixed, and calcined to the sintering point (900°—1000° C.) without fusion of the mass, the fuel consumption being about 180—200 parts of coal for 100 parts of ore. Leaching with a solution of the remainder of the requisite sodium carbonate takes place under pressure in autoclaves fitted with stirring gear, the insoluble residue being thoroughly exhausted and filter-pressed. The concentrated chromate liquor is treated with not quite the equivalent quantity of sulphuric acid, a slight excess of chromate preventing the formation of chromic acid, which would attack the iron evaporating vessels. The latter are cast in one piece with the necessary heating coils and are provided with a stirring device to prevent the deposition and burning of sodium sulphate on to the heating surfaces. The solution is evaporated to 60° B. sp. gr. 1·71), filtered and concentrated in iron basins to a paste containing 67% of chromic acid. The separated sodium sulphate is freed from bichromate by reduction with sulphur dioxide or hydrogen sulphide, and precipitation of chromic hydroxide. Newer methods of manufacture are the treatment of monochromate with ammonia, followed by carbonation and deposition of sodium bicarbonate; the use of caustic alkali in the place of alkali carbonate; and a method devised by the author, according to which only half the necessary sodium carbonate is used for decomposing the ore, the remainder being replaced by sodium sulphate, formed in the later stages of manufacture.—O. K.

Hypochlorites; Stability and oxidation potential of ——. *Contribution to catalysis and a hypochlorite-carbon cell.* K. A. Hofmann and K. Ritter. Ber., 1914, 47, 2233—2244.

Behaviour of hypochlorites at increased temperatures and in presence of carbon dioxide. The stability of nearly pure calcium hypochlorite (now available in large quantities), a mixture of hypochlorite and chloride, and bleaching powder under different conditions was compared, with the following results:—

Treatment.	Content of available chlorine* fell from:—		
	Hypochlorite.	Hypochlorite + chloride.	Bleaching powder.
	%	%	%
Seven hours at 90° C. in a current of dry, CO_2-free air	76·62 to 70·6	—	36·51 to 22·47
Eight days in shallow dishes in still, moist air containing CO_2	76·52 to 52·45	46·30 to 21·05	36·51 to 18·18
Five hours in dry carbon dioxide ..	76·52 to 66·66	46·3 to 36	36·51 to *nil*

* Total oxidising power as determined with acidified potassium iodide solution, calculated to free chlorine.

In a current of moist carbon dioxide the three products all lost the whole of their available chlorine, but whilst chlorine alone was evolved from the bleaching powder and the mixture of hypochlorite and chloride, the pure hypochlorite gave a mixture of chlorine and hypochlorous acid. The free hypochlorous acid produced by the action of a slow current of carbon dioxide on a solution of calcium hypochlorite was largely decomposed: $4HClO = HClO_3 + HCl + Cl_2 + H_2O$; with a solution of bleaching powder the free chlorine was increased at the expense of the chlorate. With ammonia both bleaching powder and calcium hypochlorite gave a nearly quantitative yield of nitrogen.

Behaviour of hypochlorite and bleaching powder with catalysers. Distinction between oxygen-carriers and oxygen-evolving catalysers. The experiments were made with solutions of calcium hypochlorite and bleaching powder respectively, which had been shaken with excess of lime and filtered. With both solutions vigorous decomposition was effected by oxides of cobalt, nickel, and iridium, whilst oxides of chromium, iron, manganese, uranium, bismuth, palladium, osmium, thallium, and vanadium had practically no effect. In presence of ruthenium and rhodium salts the hypochlorite was more stable than the bleaching powder, whilst the reverse was the case in presence of copper sulphate and lead nitrate. The view that the activity of hypochlorites and other oxidising agents such as hydrogen peroxide, can be increased by addition of oxygen-evolving catalysers is incorrect, and in this respect a distinction must be drawn between the catalysers mentioned and oxygen-carriers. With the latter, *e.g.*, osmium tetroxide, intermediate products of higher oxidation-potential are formed, and hence the oxidising power is increased, but oxygen-evolving catalysers, *e.g.*, iridium and cobalt oxide, are capable only of inducing (presumably by surface condensation) the interacion of at least two mols. of hypochlorite with liberation of gaseous oxygen, without any appreciable effect on oxidisable substances which may be present.

Oxidation-potential of hypochlorites and its electromotive utilisation. Using unattackable electrodes of platinum, magnetite, or gold, the potential of calcium hypochlorite solution saturated with calcium hydroxide, in two experiments, was 0·938 and 0·931 volt respectively referred to the standard hydrogen electrode; that of a bleaching powder solution saturated with calcium hydroxide was 0·953 volt. Solutions of sodium hypochlorite gave somewhat higher values when made alkaline with sodium carbonate and somewhat lower values when made alkaline with sodium hydroxide. A cell of the following construction:

platinum in a solution of sodium hypochlorite containing sodium carbonate	20% solution of sodium chloride	zinc in 10% solution of caustic soda + zinc oxide

gave an E.M.F. of 2·24 volts and a current yield of 92·2% of the oxygen consumed. A cell of the Meidinger type, of similar composition to the foregoing, except that a 50% solution of potassium carbonate was used instead of the sodium chloride solution gave a nearly quantitative current yield, and after continuous withdrawal of current a potential of 2·1 volts was always again obtained. Cells were also constructed with carbon anodes. The cell:

platinum in alkaline sodium hypochlorite solution	2N-caustic soda solution	beechwood charcoal in platinum wire gauze immersed in 2N-caustic soda

gave an initial E.M.F. of 0·76—0·91 volt, falling to 0·7—0·87 volt after withdrawal of current; the current-yield was 74—76%, and the electromotively active oxygen was converted almost quantitatively into carbon dioxide. It is thus possible to oxidise carbon at the ordinary temperature in a cell from which current can be withdrawn continuously, but an improved carbon electrode capable of combining more rapidly with oxygen is necessary before such a cell will be useful for practical purposes.—A. S.

Ammonium chloride; Mixed crystals of —— with manganese chloride. H. W. Foote and B. Saxton. J. Amer. Chem. Soc., 1914, **36**, 1695—1704.

THE solubility of varying mixtures of ammonium chloride and manganese chloride in water at 25° C. was determined, both residues and solutions being analysed, and the composition of the solid phases thus ascertained. The results are given in tables and a curve diagram and show that one double salt, $2NH_4Cl,MnCl_2,2H_2O$, is formed, and that this forms with ammonium chloride two series of solid solutions; there is a gap between the limiting compositions of each type, which are approximately:—α-crystals: NH_4Cl 74, $MnCl_2$ 20, H_2O 6%; β-crystals: NH_4Cl 64, $MnCl_2$ 28, H_2O 8%.—A. S.

Calcium nitrate. Part III. The three-component system: calcium nitrate, lime, water. H. Bassett, jun., and H. S. Taylor. Chem. Soc. Trans., 1914, **105**, 1926—1941. (See also this J., 1912, 332.)

BY the investigation at 25° and 100° C. of the solid phases in equilibrium with calcium nitrate solutions containing free lime, the basic nitrate, $Ca_2N_2O_7$, and its several hydrates, but no series of solid solutions $CaO, x N_2O_5, y H_2O$ (Cameron and Robinson, this J., 1907, 1197) were found. —O. E. M.

Polysulphides of calcium. G. A. Barbieri. Atti R. Accad. dei Lincei, Roma, 1914, **23**, II., 8—12.

THE author has shown previously (Atti R. Accad. dei Lincei, Roma, 1910, **19**, II., 584; Z. anorg. Chem., 1911, **71**, 347) that unstable hydrated salts may frequently be isolated in the form of addition-compounds with hexamethylenetetramine. By the interaction of calcium chloride with ammonium pentasulphide and with an ammonium polysulphide solution containing a smaller proportion of sulphur, in presence of hexamethylenetetramine, the two compounds, $CaS_5,10H_2O,2C_6N_4H_{12}$ and $CaS_4,10H_2O,2C_6N_4H_{12}$, respectively were formed as orange-yellow crystalline substances By treating aqueous solutions of calcium polysulphides with hexamethylenetetramine and analysing the precipitates produced, it was found that the solution obtained by boiling sulphur with milk of lime contained the tetrasulphide and that obtained by heating sulphur with calcium hydrosulphide solution contained the pentasulphide of calcium.—A. S.

Niobium; Reduction of quinquevalent ——. A. Stähler Ber., 1914, **47**, 841—843.

SOLUTIONS of niobic acid in hydrochloric or sulphuric acids and of niobium pentachloride in hydrochloric acid whe reduced electrolytically became intensely blue, but n chlorides or sulphates of the type, $NbCl_3,6H_2O$ o $Nb_2(SO_4)_3$, could be isolated as is the case with titaniu and vanadium. Evidence was forthcoming that the blu solution was of a colloidal character and contained substance which separated on the addition of ammoniu chloride, and was very similar to molybdenum blue Th reduction of solutions of quinquevalent niobium with zin or by electrolysis using a lead amalgam cathode gav brown solutions which behaved with ammonia, hydroge peroxide, mercuric chloride, etc., in a manner similar t trivalent titanium. This solution also reduced copp sulphate to metallic copper. The blue solution obtaine by electrolysis gave with gold chloride a "niobium purple similar to "purple of cassius," probably consisting colloidal gold adsorbed by niobic acid.—G. F. M.

Radium emanation, Action of —— on mixtures of hydrog and oxygen O. Scheuer. Comptes rend., 1914, 15 423—426.

IN mixtures of hydrogen and oxygen produced by electr lysis, rapid combination occurs under the influence radium emanation, whether the latter is mixed with t gases or enclosed in a bulb. The ratio of the number molecules of gas combined to the number of pairs of io formed per Curie-second, is independent of the pressu of the gas and amounts to 5·4—5·6 : 1 when the emanati is mixed with the gas. The products are water and smal quantities of hydrogen peroxide; the greater part of the former is probably produced by decomposition of hydrogen peroxide. No ozone is produced and only minute quantities are formed by the action of radium emanation on pure oxygen.—J. H. L.

Bromine hydrate. H. Giran. Comptes rend., 1914, **159**, 246—248.

The method of thermal analysis showed that bromine hydrate has the formula, Br_2+8H_2O, and this was confirmed by a determination of bromine in the crystals dried in a centrifuge.—F. Sodn.

Kelp industry; The ——. Report to the Board of Agriculture for Scotland on Home Industries in the Highlands and Islands, 1914, 118—131. [Cd. 7564.]

There has been a marked increase in the production of kelp since 1905, and the conditions are favourable for further extensions and developments, especially in respect to improved methods of collection and utilisation, since the South American sodium nitrate deposits, from which four-fifths of the present supply of iodine is derived, are being gradually depleted. The Scottish sea-weeds are considerably richer in iodine than the giant kelps of the Pacific and the Japanese seaweeds. Two methods of utilisation of the algæ are available, the dry method of burning or carbonising and the wet method (see Stanford, this J., 1884, 297; 1886, 218; 1894, 698), although up to the present the latter has proved expensive in actual commercial working. In the United States a large company is now engaged in the manufacture of potassium salts from kelp on a commercial scale. The kelp is collected at sea by a boat fitted with a power-driven cutting device which can be lowered to about 8 ft. below the keel. From the boat the kelp is delivered to an elevator and carried to a closed dryer in which it is kept in constant motion at not above 100° C. The drying should follow as soon after collection as possible, since the value of the sea-weed is reduced by exposure to the air. The dried weed is calcined at not above 400° C. in a brick kiln having a fireclay lining and a cast-iron grate through which air enters. The volatile products pass to condensers through a tar chamber kept at an uniform temperature at the top and superheated at the bottom. The ash is treated for the recovery of potassium salts, iodine, etc. The following products are manufactured at the factory: calcium, sodium and magnesium sulphates, potassium chloride, cyanide, chlorate, and nitrate, sodium chloride, calcium carbonate, carbon, iodine, bromine, ivory black, varnish gum, creosote, alcohol, acetone, and combustible gas. (See also this J., 1910, 150.)—A. S.

Hydrogen; Dissociation of —— into atoms. I. Langmuir and G. M. J. Mackay. J. Amer. Chem. Soc., 1914, **36**, 1708—1722.

Evidence in favour of the view that at high temperatures hydrogen is dissociated into atoms is summarised as follows:—The loss of heat from electrically heated tungsten wires in nitrogen, mercury vapour, argon, and carbon monoxide varies with the temperature exactly in accordance with theory (Phys. Rev., 1912, **34**, 401). In hydrogen, however, the loss of heat rapidly increases above 1900° K. (K signifies absolute scale of temperature) and at 3500° K. is more than four times the calculated value; no secondary electrical effects capable of explaining the increase can be detected. At low pressures the loss of heat from tungsten wires is greater than at atmospheric pressure in hydrogen, but not in other gases. When a wire of tungsten, platinum, or palladium is heated above 1300° K. in hydrogen at a very low pressure (0·001—0·02 mm.), the hydrogen slowly disappears. It is not absorbed by the wire but is deposited on the glass (sometimes in tubing a long distance from the bulb), especially when this is cooled by liquid air; ordinary hydrogen is liberated when the cooled portions are heated. The hydrogen which deposits in this way on glass is very active chemically, reacting with oxygen and phosphorus at the ordinary temperature. It is capable of diffusing through long tubes (at low pressures) and will then dissolve in platinum (at 50° C.), causing a marked increase in the electrical resistance of the metal and a corresponding decrease in its temperature-coefficient. The active hydrogen is not affected by an electrostatic field and therefore does not consist of hydrogen ions. Tungstic oxide, platinum oxide, and other substances contained in a tungsten filament lamp together with hydrogen at very low pressure, are rapidly reduced when the filament is heated above 1700° K., although otherwise they are not affected by hydrogen. (See also Langmuir, J. Amer. Chem. Soc., 1912, **34**, 1310; Freeman, *ibid.*, 1913, **35**, 927.) —A. S.

Potash in California. Oil, Paint, and Drug. Rep., Sept. 7th, 1914. [T.R.]

The first American potash will be produced by the Searles Lake plant within three months. The initial output will only be about five tons a day, but the plant under construction is expected to produce 120 tons a day.

Detection of nitric acid with ferrous sulphate. Bellucci. *See* XXIII.

Determination of sulphur in spent oxide. Marsden. *See* IIa.

Patents.

Sulphuric acid and other liquids; Concentration of ——. J. F. Carmichael, Liverpool, and F. Guillaume, Brussels. Eng. Pat. 15,678, July 7, 1913.

In apparatus for the concentration of sulphuric acid by the "cascade" process, each basin is provided with a half-tube of semi-circular cross-section, curved so as to lie with its edges against the sides of the basin, from near the bottom up to, beyond, and overhanging the lip of the vessel; the arrangement, which is detachable, ensures the overflow of the densest liquid from the bottom of each basin.—O. R.

Sulphuric acid; Method of manufacturing ——. I. P. Lihme, Lakewood, Ohio, Assignor to The Grasselli Chem. Co., Cleveland, Ohio. U.S. Pat. 1,103,522, July 14, 1914; date of appl., June 12, 1913.

Burner gases are filtered and brought in contact at not above 100° C. (preferably at 70°—90° C.) with a metallic oxide (*e.g.*, iron oxide) capable of absorbing hydrogen arsenide and the like. After further filtering, the gases may then be subjected to the catalytic action of platinum. —F. Sodn.

Radio-active barium compounds; Method of treating ——. H. N. McCoy, Chicago, Ill. U.S. Pat. 1,103,600, July 14, 1914; date of appl., March 27, 1914.

The separation and concentration of radio-active substances, such as radium, mesothorium-one, and thorium-X, from barium compounds is effected by converting the barium and radio-active elements into hydroxides, and fractionally separating the barium hydroxide from the solution. Partial precipitation of the hydroxides of barium and the radio-elements is preferably brought about by adding alkali hydroxide.—F. Sodn.

Bisulphite of soda; Process of making ——. H. Howard, Boston, Mass. U.S. Pat. 1,104,897, July 28, 1914; date of appl., March 17, 1913.

A calcium compound, such as "lime mud," is heated, between 30° and 90° C., in contact with sodium sulphate and sulphur dioxide in a suitable vehicle.—B. N.

Bleaching solutions containing titanous chloride and method of producing the same. A. J. Rossi, Niagara Falls, N.Y., Assignor to The Titanium Alloy Manufacturing Co., Ltd., New York. U.S. Pat. 1,105,308, July 28, 1914; date of appl., April 18, 1912.

An alloy of iron and titanium containing less than 50% Ti is dissolved in dilute hydrochloric acid; the solution is evaporated under reduced pressure below 100° C. and the crystals of ferrous chloride are removed until the proportion of titanous chloride is predominant, the liquid being finally filtered.—J. F. B.

Titanium-oxygen compounds; Process for preparing ——. P. Farup. Ger. Pat. 276,025, July 2, 1913.

ILMENITE or other titaniferous iron ore is finely ground and mixed with one to two parts by weight of concentrated sulphuric acid, the mixture being heated if necessary; the sulphate mass is heated to about 600° C., whereupon the titanium sulphate is decomposed, but not the iron sulphate, which can be removed by washing, leaving 80% crude titanic acid. This may be purified by heating with sulphuric acid or an acid sulphate, mixing with common salt or other metallic chloride, and heating the product to 700° C. and extracting with water; white titanium oxide is thus produced.—T. F. B.

Hydrosulphites; Electrolytic preparation of ——. Badische Anilin und Soda Fabrik. Ger. Pats. (A) 276,058 and (B) 276,059, July 7, 1912.

(A.) A DILUTE solution of sodium bisulphite is electrolysed in the cathode compartment of an electrolytic cell; a neutral salt, such as a chloride or sulphate, but not a normal sulphite, may be added to the bisulphite. (B.) During the electrolysis, free acid, especially sulphurous acid, or more bisulphite, is added to the bisulphite solution, and the process is carried out at a low temperature (0°—5° C.).—T. F. B.

Seaweeds; Process for the treatment of —— for the extraction of their elements. M. P. P. Gloess, L. P. J. Darrasse, and E. R. Darrasse, Paris, France. U.S. Pat. 1,103,283, July 14, 1914; date of appl., July 1, 1913.

SEAWEED is treated with a non-alkaline oxidising agent, to extract iodine and mineral salts, then with an alkaline oxidising agent, to dissolve, and render more viscous and detersive, the mucilaginous constituents, and, finally, the cellulose is obtained as a residue.—F. SODN.

Iodine from marine algae; Industrial extraction of ——. L. Laurent. Fr. Pat. 467,768, April 4, 1913.

THE raw material is washed with fresh water, macerated, treated with liquors containing potassium salts and or sodium bicarbonate, pressed, and filtered; the filtrate is clarified with alum and treated with chlorine or other reagents for the liberation of iodine.—O. R.

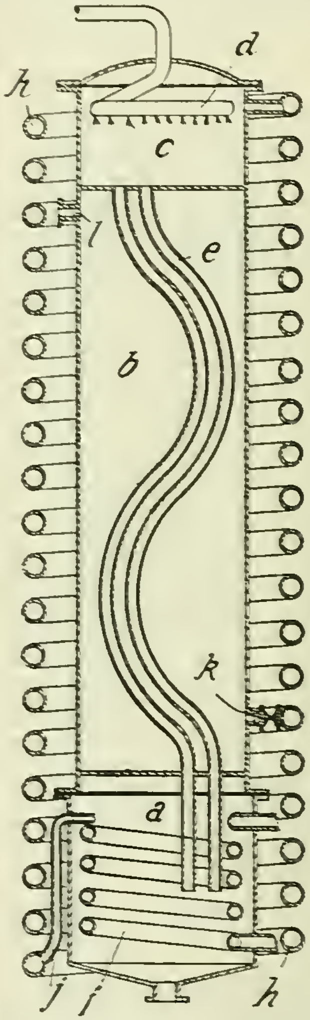
Hydrogen gas; Process for the manufacture of ——. Berlin-Anhaltische Maschinenbau-A.-G., Berlin. Eng. Pat. 6155, March 11, 1914. Under Int. Conv., March 12, 1913.

IN the manufacture of hydrogen by the alternate reduction and oxidation of ferric oxide and iron respectively, a gas producer is ranged alongside of an ore or reaction chamber, and is separated from it by a gas purifier. Compressed air from a blower and superheated steam have access to both the producer and the reaction chamber. Producer gas is first generated in the producer and burnt with an excess of air in the reaction chamber, thereby raising the latter to the desired temperature, burning carbon, which has been deposited, and destroying iron sulphide, which has been formed, throughout the reaction mass. Water-gas is then generated in the producer and slowly admitted to the reaction chamber for the reducing phase, after which steam is passed over the spongy iron for the generation of hydrogen.—O. R.

Hydrogen by the decomposition of steam: Manufacture of ——. J. Pintsch A.-G. Fr. Pat. 466,739, Dec. 30, 1913.

FOR the manufacture of hydrogen from steam and iron, blocks or briquettes are prepared from natural or artificial iron oxides or carbonates, and natural or artificial oxides or carbonates of magnesium, barium, strontium, or aluminium. The ferruginous material is made into a paste with water and one of the above-mentioned materials, moulded, dried, and calcined. A mixture of the oxides or carbonates of calcium and magnesium, containing 75% of the latter in excess over the former, forms a suitable binding material for furnishing the requisite porosity and strength.—O. R.

Oxygen; Process for the manufacture of —— by the fractional distillation of liquid air. L. Simon. Fr. Pat. 466,685, Dec. 27, 1913. Under Int. Conv., May 28, 1913.



LIQUID air is introduced through *d*, into the chamber, *c*, and is fractionated in the worm, *e*, liquid oxygen flowing into the chamber, *a*, and nitrogen passing through the top of the apparatus into the interchanger, *h*. Oxygen, heated by the coils, *f*, passes through the conduit, *j*, into the interchanger, *h*, in counter-current to the stream of nitrogen. The latter passes into the chamber, *b*, by way of the valve, *k*, and serves to heat the worm, *e*, before escaping at *l*, the fractionation of the liquid air by the escaping nitrogen being an essential feature of the process.—O. R.

Marine plants; Process of treating —— [extraction of iodine, etc.]. M. P. P. Gloess, Paris. Eng. Pat. 15,159, July 1, 1913. Under Int. Conv., July 4, 1912.

SEE U.S. Pat. 1,103,283 of 1914; preceding.—T. F. B.

Ammonium sulphate; Producing ——. C. Bosch, Assignor to Badische Anilin und Soda Fabrik, Ludwigshafen on Rhine, Germany. U.S. Pat. 1,106,919, Aug. 11, 1914; date of appl., April 19, 1913.

SEE Eng. Pats. 12,845 and 14,114 of 1912; this J., 1913 363.—T. F. B.

Calcium cyanamide; Process and furnace for the continuous manufacture of ——. J. H. Lidholm, and Dettifoss Power Co., Ltd. Fr. Pat. 468,128, Feb. 6, 1914. Under Int. Conv., Feb. 18, 1913.

SEE Eng. Pat. 3546 of 1914; this J., 1914, 644.—T. F. B.

Alkali peroxides : Process and apparatus for making ——. E. Marguet. Fr. Pat. 468,375, April 22, 1913.

See Eng. Pat. 11,174 of 1913 ; this J., 1914, 136.—T. F. B.

Electrolysis of alkali halides ; Process and apparatus for the ——. Siemens und Halske A.-G. Fr. Pat. 468,645, Feb. 19, 1914. Under Int. Conv., Feb. 20, 1913.

See Eng. Pat. 18,102 of 1913 ; this J., 1914, 23.—T. F. B.

Hydrosulphite ; Process for producing anhydrous ——. Kinzlberger und Co. Fr. Pat. 469,060, May 9, 1913.

See Eng. Pat. 11,010 of 1913 ; this J., 1914, 643.—T. F. B.

Manufacture of cement from spent or waste lime. Eng. Pat. 25,572. *See* IX.

Feeding devices for rotating furnaces [for pyrites]. Eng. Pat. 3581. *See* X.

VIII.—GLASS ; CERAMICS.

Glass ; The cohesion point, a new constant of ——. E. Zschimmer. Silikat-Zeits., 1914, 2, 129—135.

When two clean plane polished glass surfaces are pressed together a firmly adhering combination is obtained, in which however the surfaces are separated by an air layer at least 0·047 mm. thick, and a greyish blue interference colour is produced. The condition is merely one of *adhesion*, the intimate molecular contact of the glass being wanting which is the necessary condition for *cohesion* between the two surfaces. At high temperatures the adhesion slowly passes within a certain length of time into cohesion. The temperature required to bring this about in a specified time is named the *cohesion-point*. It is a constant of the particular variety of glass, which relatively defines its specific softening properties, and allows the course of liquefaction to be exactly followed. It is, in fact, a substitute for the melting point constant of crystalline substances. If cohesion points are plotted against corresponding times of heating a representation of the softening of the heated glass is obtained. In practice 30 mins. may be adopted as the standard time of heating required to produce coherence of the surfaces. The glass, in the form of discs, 10 mm. diam. and 2 mm. thick, adhering in pairs, is heated in an electric tube furnace (see Zschimmer and Schielz, Silikat-Zeits., 1914, 2, 45). The course of the coherence is easily followed ; a black spot surrounded by Newton rings first appears, and gradually increases in size, eventually at the completion of coherence extending over the whole disc. The end-point is easily recognised. Numerous tables and curves are given showing the values of the constant for many varieties of glass.—G. F. M.

Patents.

Glass or the like ; Process for shaping, graduating, or calibrating tubes of ——. K. Küppers, Aachen, Germany. Eng. Pat. 20,192, Sept. 6, 1913.

Glass tubes of definite length and cross-section are produced by heating and softening the walls of the tube which are then by gradual stages pressed into contact with a suitably shaped mandrel. The necessary external pressure may be either mechanical or produced by suitably exhausting the tube enclosing the mandrel. A tube rotated about an axis may also be melted on to the mandrel by means of a progressive heating apparatus. The mandrels may be dissectible, and also provided with words, figures or graduations which are accurately transferred to the glass tube pressed on them.—W. C. H.

Glass furnace. R. H. Miller, Assignor to Laclede-Christy Clay Products Co., St. Louis, Mo. U.S. Pat. 1,104,375, July 21, 1914 ; date of appl., April 11, 1912.

The walls of the furnace enclose a rectangular hearth-chamber, and each of the end walls contains a number of mixing-chambers, with burner openings leading therefrom to the hearth-chamber. Gas- and air-ducts lead to the mixing-chambers, the gas and air mixing on entering the chamber. The bottom wall of the hearth-chamber is provided near the centre with a down-draught opening, and a deflecting wall located beneath this opening serves to divide the discharged gas.—B. N.

Glass furnaces. Soc. Française d'Exploitation de Fours Spéciaux à Haute Température. Fourth Addition, dated Dec. 4, 1913, to Fr. Pat. 390,102, May 11, 1908 (this J., 1908, 1020 ; 1909, 141 ; and 1910, 1311).

Each furnace is combined with two regenerative chambers and provided with a fan, affording communication with each regenerator and a central column.—O. R.

Pottery or china-ware ; Method of producing translucent ornaments or designs in ——. R. Greifelt, Berlin. Eng. Pat. 10,985, May 4, 1914. Under Int. Conv., May 6, 1913.

The required pictures, patterns or designs are produced by applying to the plaster mould in which the pottery article is cast, a layer of highly translucent material of a lower melting temperature and by covering this with a less translucent material of a higher melting temperature but with the same coefficient of shrinkage. Only a thin layer of the latter is left on the translucent material and the articles are burned, glazed and finally burned in ordinary pottery furnaces.—W. C. H.

Enamels and process of making them. M. Mayer, Templehof, and B. Havas, Assignors to Chemisch Metallurgische Indus. G. m. b. H., Berlin. U.S. Pat. 1,104,266, July 21, 1914 ; date of appl., Nov. 19, 1912.

A white opaque enamel is produced by adding to the enamel proper a suitable white refractory material and an agent containing spinel for rendering the material opaque. —B. N.

Enamelling composition. I. Kreidl, Vienna. U.S. Pat. 1,104,679, July 21, 1914 ; date of appl., April 25, 1914.

The enamel contains a colloidal metallic oxide, such as zirconium oxide, to render it opaque.—B. N.

Kilns for making tiles, pottery, and similar articles. C. Dressler. Second Addition, dated Jan. 31, 1914, to Fr. Pat. 432,427, July 21, 1911. Under Int. Conv., April 10, 1913.

See Eng. Pat. 8505 of 1913 ; this J., 1914, 540.—T. F. B.

Enamels ; Opaqueing agents for the production of white ——, *and process for the manufacture of such opaqueing agents.* Verein. Chem. Fabriken, Landau, Kreidl, Heller und Co., Vienna. Eng. Pat. 17,998, Aug. 7, 1913. Under Int. Conv., Oct. 1, 1912.

See Fr. Pat. 462,587 of 1913 ; this J., 1914, 314.—T. F. B.

IX.—BUILDING MATERIALS.

Gypsum ; Dehydration of ——. C. Gaudefroy. Comptes rend., 1914, 159, 263—264. (See also this J., 1914, 791.)

The hemihydrate was obtained as prismatic needles which underwent no change of form when converted into the anhydride, but evidence is adduced to show that the two states are chemically distinct.—F. Soddy.

Patents.

Cement; Process for the manufacture of —— out of spent or waste lime. R. Illemann, Glasgow. Eng. Pat. 25,572, Nov. 8, 1913.

Spent or "killed" lime (from the manufacture of soda by the Leblanc process), which has been exposed to atmospheric influences, is heated to 1000°—1500° F. (538°—816° C.), according as a quick- or slow-setting cement is required, then ground and mixed with water. (Reference is directed to Eng. Pats. 15,406 of 1889 and 9412 of 1903; this J., 1890, 944; 1904, 61.)

—W. E. F. P.

Magnesite and dolomite; Process of making sintered ——. E. Pohl, Rhöndorf-on-the-Rhine, Germany. U.S. Pat. 1,103,375, July 14, 1914; date of appl., April 8, 1913.

A mixture of pure raw materials and those containing sintering ingredients, such as iron and clay, is worked into a mealy mass of uniform composition and burnt to a sintered condition.—F. Sodn.

Cement or hydraulic lime from sulphate of lime; Process of manufacturing ——. L. P. Basset, Montmorency, France. Eng. Pat. 23,538, Oct. 17, 1913. Under Int. Conv., Oct. 21, 1912. Addition to Eng. Pat. 12,027, May 21, 1912.

See Addition of Oct. 21, 1912, to Fr. Pat. 455,062; this J., 1913, 945.—T. F. B.

X.—METALS; METALLURGY, INCLUDING ELECTRO-METALLURGY.

Water with iron and with ferrous oxide; Reversible reactions of ——. G. Chaudron. Comptes rend., 1914, **159**, 237—239.

The action of steam on iron, between 300° and 1000° C., involves two series of equilibria, the solid phases being mixtures of iron and ferrous oxide and of ferrous oxide and magnetic oxide respectively. Tables showing the equilibrium pressure ratios of water vapour to hydrogen, are given for each series.—F. Sodn.

Iron-zinc alloys. F. Taboury. Comptes rend., 1914, **159**, 241—243. (See also Wologdine, this J., 1907, 97.)

Crystalline deposits from galvanising baths, separating somewhat above 422° C., were in all cases constituted of solid solutions containing 7·3% Fe (see von Vegesack, this J., 1907, 153). There was no evidence that these reacted with zinc at a lower temperature, even when slowly cooled, to form mixed crystals containing 0·7% Fe (*loc. cit.*).—F. Sodn.

Iridium; Determination of —— in platinum-iridium alloys. C. O. Bannister and E. A. Du Vergier. Analyst, 1914, **39**, 340—346.

The following methods were used for the analysis of two platinum-iridium alloys containing respectively 20 and 25% Ir:—

Silver method. 0·25 grm. of alloy and 1·5 of pure silver were cupelled (finally at a high temperature) with 10 grms. of assay lead, the button rolled into cornet form as usual, and "parted" with boiling concentrated sulphuric acid (2 successive portions of 40 c.c.); the residue was digested first with 10 and then with 5 c.c. of dilute *aqua regia* (HCl 4, HNO_3 1, H_2O 10, parts by vol.) to dissolve the platinum, then washed with water, dilute ammonia (to remove AgCl) and water in succession, ignited at a high temperature, and weighed as iridium.

Lead method. 0·5 grm. of alloy was heated for 1 hr. (in a wind furnace) with 5 grms. of assay lead in a carbon crucible contained in a covered clay crucible packed with charcoal, and allowed to cool slowly. The lead button was digested with two successive portions of 50 c.c. of dilute nitric acid (1 : 10), the insoluble residue treated with dilute *aqua regia*, and the process concluded as in the preceding method. In both methods platinum was determined (in the *aqua regia* solution) by precipitation with pure zinc and subsequent ignition of the metal in hydrogen; but it is customary to take this constituent by difference. The results obtained were as follow:—

Approximate composition of alloy.		By silver method.	By lead method.
	%	%	%
Iridium	20	20·20 20·40	20·60 20·40
Platinum	80	79·76 79·52	79·30 79·60
Iridium	25	25·20 25·24	25·32 25·28
Platinum	75	74·68 74·56	74·52 74·60

—W. E. F. P.

[*Silver.*] *Cyaniding a furnace product (speiss).* H. A. Megraw. Eng. and Min. J., 1914, **98**, 147—149.

The speiss produced at Deloro, Ontario, by smelting high-grade silver ore from the Cobalt district, contains As 25, Co 20—25, Ni 12—15, Fe 15—20, S 5—10, Cu 0·5—2%, and Ag 1400 oz. per ton. After being crushed to 40-mesh size and roasted to remove sulphur and arsenic (of which latter 6—7% remains in the product) the material is subjected to a chloridising roast, to convert silver into chloride, and then agitated for 6 hrs. with a 1% solution of sodium cyanide to which caustic soda is added to facilitate subsequent precipitation of the silver from the decanted liquid by means of aluminium dust (process of Hamilton and Kirkpatrick). The consumptions of aluminium and soda are respectively 8·9 and 29·8 lb. per 1000 oz. of silver recovered, that of cyanide being 11 lb. per ton of speiss treated. The silver precipitate is melted with small quantities of borax and soda, the fineness of the bullion produced being over 999. The residue from the cyanide process is treated for the recovery of cobalt and nickel oxides.—W. E. F. P.

Iodine and silver; Gases retained by ——. P. A. Guye and F. E. E. Germann. Comptes rend., 1914, **159**, 225—227.

The gases expelled from metallic silver, during its conversion into silver iodide (see Guichard, this J., 1911, 1018), contained oxygen (80%) and carbon monoxide, 0·17 c.c. of gas being obtained from 1 grm. of metal. Silver purified by melting in a current of hydrogen yielded no oxygen, but about the same volume of carbon monoxide, when treated by the iodine method. The iodine employed was purified by sublimation *in vacuo*, which furnished 10 cb. mm. of gas per grm.—F. Sodn.

Empressite, a new silver-tellurium mineral from Colorado. W. M. Bradley. Amer. J. Sci., 1914, **38**, 163—165.

A mineral discovered in the Empress-Josephine mine, Kerber Creek, associated with galena and native tellurium, had metallic lustre, greyish-black streak, conchoidal fracture, hardness 3—3·5, sp. gr. 7·51, and the composition AgTe.—O. R.

Copper; Precipitation of —— from solution. F. Laist and F. F. Frick. Min. and Eng. World, 1914, **41**, 152—157.

The solution obtained from an 80-ton leaching plant, and containing Cu, 1·91, $Fe_2O_3+Al_2O_3$, 3·88, NaCl, 8·3%, Ag, 0·634 oz. per ton, was not suitable for electrolytic treatment, on account of the high proportion of chlorine; and precipitation with scrap or spongy iron involved the waste of one-fourth of the leaching solution at each operation in order to avoid the accumulation of iron sulphate. Experiments were therefore made with hydrogen sulphide, generated from matte and also from alcium sulphate, and with sulphur dioxide from roasting urnace gases. The hydrogen sulphide process could be orked with a high efficiency, provided that the generator ad an agitating device, and the absorber was properly esigned. The acid used for generating the gas is recovered, he leaching solution is not fouled, a high-grade copper ulphide is produced which can be readily smelted, and he copper matte used in generating the hydrogen sulphide enriched by the removal of iron and sulphur. The est conditions for precipitation with sulphur dioxide ere saturation of the cold solution by a gas, containing at ast 10% SO_2, at a pressure of 15 lb. per sq. in., heating boiling under 20 lb. pressure and then cooling to 0—70 F. (15·5°—21° C.). About 90% of the copper ould be precipitated. The equation given is:— $CuCl_2+SO_2+2H_2O=Cu_2Cl_2+H_2SO_4+2HCl$, but a rther quantity of acid is regenerated by the reduction f ferric salts and by a catalytic action of the cuprous hloride. The cuprous chloride can be reduced by means f iron sponge, by coke and limestone, or electrolytically. he reaction with iron is $Cu_2Cl_2+Fe=2Cu+FeCl_2$, only alf as much iron being required as for direct precipitation. process was worked out for preparing spongy iron, r precipitating the copper. The iron was made by ducing with coke a calcine assaying SiO_2, 4·3; FeO, 72·2; 4·2; Cu, 6·2; Fe, 56·2%, obtained by roasting a ncentrate rich in iron sulphide. A rotary kiln was sed for the reducing process, with an oil burner at one d, a conduit leading to a stack at the other, and a charg- g and discharging door at the centre enclosed by an air- ght casing to prevent oxidation of the reduced iron. he charge of 1400 lb. of calcine was first introduced d heated to 1300° F. (700° C.). About 600 lb. of coal as then introduced in small lots, and the oil flame was opped until the hydrocarbons were burned off. The arge was then heated to 1700° F. (930° C.), when duction was complete, and the product was discharged d quenched. The reduction is effected by mixing ongy iron to a paste with the cuprous chloride solution. xperiments made by smelting briquettes composed of oist cuprous chloride 100, limestone 75, coke 10 and ment 5 parts, indicated that with a suitable installation % of the copper could be recovered as metal and in e slag, and that 75% of the remaining volatile copper uld be recovered by milk of lime. Electrolytic reduction as also tried with promising results.—A. T. L.

opper.] *Electrolytic refining; Ampère efficiency in* ——. K. S. Guiterman. Eng. and Min. J., 1914, **98**, 338—341.

ESTS were made under conditions approximating to ose of actual practice, the temperature, circulation, idity and copper content of the electrolyte, and the rrent density, being practically constant throughout. he electrolyte was a solution of pure copper sulphate, ntaining free sulphuric acid, to which glue and salt n quantities equivalent to 12—16 lb. per day per 170,000 . ft. of electrolyte), arsenic (up to 1·8%), iron (up to 1%), d hydrogen peroxide (sufficient to oxidise 2/3 of the iron) ere added in succession; anodes of pure, and also of ster copper were used. The average current efficiency as 95% with the pure materials; and varied between and 97% in all other experiments. Ferric iron was und to be quickly reduced to the ferrous condition during ectrolysis.—W. E. F. P.

pper; *Tensile properties of* —— *at high temperatures.* G. D. Bengough and D. Hanson. [Advance proof of paper taken as read at the Statutory Meeting of Inst. of Metals, London, Sept. 10, 1914.] (See also this J., 1912, 134.)

ARS of B.S., electrolytic, and "arsenical" copper (As 13%) were heated in oxidising, neutral, and reducing mospheres respectively. An oxidising atmosphere at gh temperatures produced high ductility. In a neutral mosphere, unannealed rolled copper had a greater nsile strength and was less ductile than the annealed etal at all temperatures up to 1000° C. In annealed pper, the fracture passed through the crystals below out 700°, and between the crystals above 750° C. The istence of a range of low ductility at 250°—450° C. was confirmed. Small quantities of oxygen or arsenic lowered the tensile strength at high temperatures. The tensile strength in hydrogen above 720° C. was about ½ ton per sq. in. lower than in an oxidising or neutral atmosphere.
—W. R. S.

Copper; Specific heat of —— *in the interval* 0—50 C. D. R. Harper. J. Franklin Inst., 1914, **178**, 234—236.

A LONG copper wire (50 metres) suspended *in vacuo* and forming part of an electric-circuit was heated by the current 4′—5° C. in each experiment, and the rise of temperature found by using the wire itself as a resistance-thermometer. The specific heat was found to be 0·0917+0·000048 (t — 25) calories$_{20}$ per grm.-degree.
—W. R. S.

Brass; Note on the annealing of ——. F. Johnson. [Advance proof of paper taken as read at the Statutory Meeting of Inst. of Metals, London, Sept. 10, 1914.]

ADMIRALTY brass (Cu 70, Zn 29, Sn 1%) should be annealed at 760° C. with subsequent quenching, to transform the eutectoid into the homogeneous β-phase. The structural change takes place rapidly at 760° C., but is very incomplete even after prolonged heating at lower temperatures.
—W. R. S.

Copper-zinc alloys; Behaviour of —— *when heated in a vacuum.* W. E. Thorneycroft and T. Turner. [Advance proof of paper taken as read at Statutory Meeting of Inst. of Metals, London, Sept. 10, 1914.]

THIN turnings of Cu-Zn alloys containing Cu 75·12, 51·33, 43·80, 34·20, 20·10, and 10·25% respectively were heated *in vacuo* (see Nair and Turner, this J., 1913, 914) at different temperatures for 30 mins., and the residues analysed. The variation of the rate of volatilisation with rising temperature could be represented by a line which was straight throughout the greater part of its length for the alloy (Cu 75·12%) consisting entirely of the α-solid solution, but for the other alloys the curves showed considerable deviations from a straight line. The alloy with Zn 89·75% was somewhat more volatile than pure zinc. The zinc could be completely volatilised from alloys with more than 40% Cu, but with less than 40% Cu, part of the copper was volatilised with the zinc. A greater amount of heat was required to separate zinc from alloys rich in copper than was necessary to volatilise the liberated zinc. (See also this J., 1912, 134, 391.)—A. S.

Corrosion; Contributions to the history of ——. *Pt. III., Coke, condenser tubes and corrosion.* A. Philip. [Advance proof of paper taken as read at the Statutory Meeting of Inst. of Metals, London, Sept. 10, 1914.] (See also this J., 1912, 134; 1913, 292.)

THE conclus on of Bengough and Jones (this J., 1913, 913) —that the corrosion of condenser tubes by sea water is not affected by contact with particles of coke—and the evidence upon which this is based, are criticised, and abundant experimental proof given to the contrary, as regards tubes composed of Admiralty alloy (Cu 70, Zn 29, Sn 1%).—W. E. F. P.

Phosphor-bronze; Determination of phosphorus in ——. E. W. Hagmaier. Met. and Chem. Eng., 1914, **12**, 524—525.

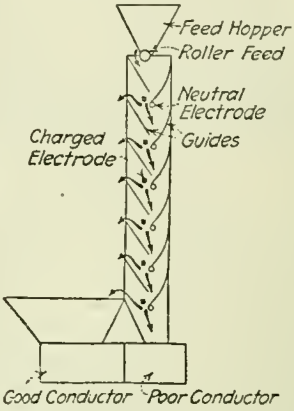
A MODIFICATION of the method previously described for the determination of phosphorus in vanadium-steel (this J., 1913, 145). 1 grm. of bronze is dissolved in 10 c.c. of strong hydrochloric and 5 of nitric acid; treated with 150 c.c. of hot water, and 10 c.c. of a solution containing 1 grm. of cerium chloride in 25 c.c. of hydrochloric acid and 200 of water, then with dilute ammonia (1 : 2) from a burette, with stirring, till a greenish-blue tint appears. 4 c.c. of acetic acid are added, and the mixture is boiled for 5—10 mins. After settling, the clear liquid is siphoned off, the precipitate washed by decantation with 100 c.c. of hot water 6—8 times, and dissolved by warming with

15 c.c. of nitric and 3 c.c. of hydrochloric acid. After cooling, 5 c.c. of ammonia (1 : 1) are added, and the phosphoric acid precipitated as usual with ammonium molybdate.—W. R. S.

Tungsten ; Analytical examination of [commercial] ——. H. Arnold. Z. anorg. Chem., 1914, **88**, 74—87.

THE metal, when in fine powder, is dissolved in a mixture of ammonia and hydrogen peroxide (or an oxidising salt, such as ammonium persulphate). Coarser crystalline powder is oxidised by igniting and moistening with nitric acid, the oxidation product being extracted with caustic soda solution containing hydrogen peroxide, and any residue again ignited. Larger pieces are dissolved electrolytically in concentrated ammonia (200 c.c., to which 1—2 grms. of ammonium persulphate are added) contained in a platinum dish which acts as cathode, the metal being the anode ; a current of 1—2 amps. at 2·5—3·5 volts is employed, and ammonia added as required to make up for loss by evaporation, any detached pieces of metal remaining being removed and weighed, or dissolved separately. Tungsten, in any state of division, may also be rapidly converted into soluble form by adding it, a very little at a time, to alkali nitrite heated nearly to fusion, in a large covered platinum crucible ; the mixture melts owing to the vigour of the reaction. The alkaline solution, containing, *e.g.*, 25 grms. WO_3, is treated with 35 c.c. of 50% tartaric acid, to convert the tungstic acid into a soluble complex salt, the mixture diluted to about 700 c.c., and sufficient hydrochloric acid added to introduce about 4% of free acid. Hydrogen sulphide is passed for many hours into the hot solution, which is then allowed to cool in a current of the gas, and the cooled liquid is kept in an atmosphere of hydrogen sulphide for 12 hours. The mixture is filtered (after warming, if gelatinised), the precipitate washed with boiled water, and dissolved in bromine-hydrochloric acid. Cu, Pb, and Bi are then separated from As, Sn, Sb, and Mo in ammoniacal tartrate solution by Finkener's method with hydrogen sulphide water, the precipitated sulphides being treated with nitric acid, Pb separated as sulphate, and Bi and Cu by ammonia. As, Sb, and Mo are precipitated with hydrogen sulphide from boiling oxalic acid solution (see Schürmann and Scharfenberg, this J., 1908, 860), and Sn determined in the filtrate by precipitation with hydrogen sulphide in acetic acid solution. The sulphides of As etc., are dissolved in warm ammonium sulphide containing sodium hydroxide, the sulpho-salts destroyed by cautious addition of hydrogen peroxide to the hot solution, and As precipitated by hydrogen sulphide, in presence of an excess of strong hydrochloric acid. Sb and Mo are again precipitated as sulphides, these are dissolved in sodium sulphide, and Sb is precipitated electrolytically (*loc. cit.*), whilst Mo is precipitated as sulphide, by acidifying the solution, and weighed as MoO_3. All the precipitates in the hydrogen sulphide group are examined for silica which is liable to be carried down. Only Mo and As offer special difficulty ; the latter is detected by Gutzeit's test and is best determined in a separate portion. Mo is shown either by the brown colour produced by ammonium sulphide in ammoniacal solution or the carmine-red colour given by thiocyanates in presence of reducing agents. If Mo be present, the filtrates from the various hydrogen sulphide precipitations must be tested by again saturating with the gas and heating in a pressure flask. The hot (alkaline) solution containing tungsten is allowed to flow slowly, in a thin stream, into strong boiling hydrochloric acid, so as to precipitate tungstic acid in granular form, and, after removing the supernatant liquid, the residue is treated with hot water containing hydrochloric acid. The united filtrates are evaporated to dryness on the water-bath, and the evaporation residue, containing possibly Al, Fe, Ni, Co, Mn, Zn, Ca, and Mg, together with about 1 grm. WO_3 (of 25 grms. taken) and large quantities of alkali or ammonium salts, is ignited in a covered platinum dish ; before all the liberated carbon is burnt away, the contained tungsten, now present as sodium tungstate, is extracted with water, and the other metals, remaining as oxides or carbonates, are then separated by known processes. In the presence of Al, the extraction of tungstate is best carried out with hot water, in a current of carbon dioxide, to decompose any alkali aluminate. Ammonium tungstate, as usually prepared, was found invariably to have the formula $(NH_4)_4W_5O_{17},2H_2O$, instead of that generally accepted.—F. SODN.

Ore separation ; Electrostatic ——. I. C. Clark. Eng. and Min. J., 1914, **98**, 264—267.



THE separator (fig.) employed in the Huff electrostatic process consists of an iron framework (earthed to prevent shocks to operators) containing two vertical series of electrodes—charged and neutral, respectively—between which, by means of a system of guides, a continuous stream of dry, sized ore is caused to fall from a hoppe above, the best conditions as to rate of flow and spacing of electrodes being ascertained by preliminary tests. The charged electrodes ar maintained at a poten tial of 20,000 volts an insulated from the iro framework, the neutra ones being in electrica contact with the latte By the action of the elec trostatic field upon th ore particles, the goo conductors among the latter become immediately charge with electricity of the same polarity as that of the elec trodes, and are repelled to the left side of the apparat as indicated ; while the poor conductors fall throug the machine by gravity before any appreciable repulsio occurs. The two products thus obtained are re-treate in separate "finishing" machines of the san kind, the "middlings" produced being conducted the dryer with the untreated ore. The electrical equi ment consists of a generator for producing an alternati current of high potential but low ampèrage ; a rectifier f changing the negative alternating-current waves in positive, pulsating waves ; and a resistance-box for reg lating the speed of the generator. The process h been successfully employed for the separation of mi from graphite flake ; slate from coal ; and metallifero minerals from various gangues.—W. E. F. P.

Molten metals ; Surface tension of ——. S. W. Smit [Advance proof of paper taken as read at the Statuto Meeting of Inst. of Metals, London, Sept. 10, 1914.]

THE capillary depression produced by plunging carb tubes (approximate diameter 1 mm.) into the molt metal was measured after solidification, and also lowering an insulated wire inside the tube until its low end made electrical contact with the molten metal. T depressions were constant at the same temperature a varied inversely as the radius of the tube. The variati for the same metal at different temperatures were sm in comparison with the depression itself. The depressi are periodic functions of the atomic weights of the met the surface tension decreasing rapidly as the ato weight increases. The capillary constants (product height of depression and radius of tube), in sq. m given are :

Metal.	Range of temp. (°C.).	Capillary constant.	Metal.	Range of temp. (°C.).	Capilla constan
Hg	15°–17°	6·72	Sn	750°–800°	14·5
Bi	700°–760°	7·53	Ag	1100°	18·5
Pb	770°–780°	8·12	Zn	590°	24·5
Sb	840°–850°	8·65	Cu	1150°	29·4
Au	1120°	11·29	Al	700°–820°	45·0

—W. R. S

letal spraying [coating]. R. K. Morcom. [Advance proof of paper taken as read at Statutory Meeting of Inst. of Metals, London, Sept. 10, 1914.]

DETAILED description is given, with diagrams, of the pistol" perfected by Schoop and Morf for coating bjects with metal by spraying, and based upon Morf's ng. Pat. 28,001 of 1912 (this J., 1912, 792). A wire of e required metal is fed into a suitable flame, where it is elted; it passes into an air-blast which breaks it up into ne particles and projects these with high velocity upon e object to be coated. The spray is cool enough to used upon inflammable objects and even explosives. ir at 80 lb. per sq. in. is employed at the rate of 45 50 cb. ft. per minute. A spray of alloy may be proced by using stranded wires. The method is useful for aking fine castings and for reproducing process ocks.—O. E. M.

letallurgical] Furnace gases ; Cooling —— before filtration. L. D. Anderson. Bull. Amer. Inst. Min. Eng., July, 1914. Eng. and Min. J., 1914, **98**, 354.

OOLING should effect the maximum coalescence of the rticles of "fume" without condensing the moisture. he gases are usually passed through flues constructed sheet steel about ⅛ in. thick, the rate of heat transssion through this material, under smelting conditions, ing about 0·02—0·04 B.T.U. per min. per sq. ft. of oling surface per 1° F. difference between the interior d exterior temperatures; the mean temperature fference (*θm*) is found from the expression

$$\theta m = (t_1 - t_2) \div \log.\frac{t_x - t_2}{t_x - t_1}$$

here t_1 and t_2 are respectively the initial and final temratures of the interior gases, and t_x the temperature of e external air. Within certain limits the cooling is oportional to the square root of the velocity of the ses; to avoid heavy deposition of heat-insulating dust the flues, it is hence advisable to maintain a high locity. In cooling by water sprays the saturation int of the gases should not be too closely approached or mpness, and destruction, of the filter-bags will result. —W. E. F. P.

ineral production of Western Australia in 1913. Board of Trade J., Sept. 10, 1914.

E quantity and value of the minerals produced in estern Australia during the years 1912 and 1913, is en by the Department of Mines of that State for the ar 1913, as follows:—

—		1912.		1913.

loys and metals ; The Widmanstätten structure in various ——. N. T. Belaiew. [Advance proof of paper taken as read at the Statutory Meeting of Inst. of Metals, London, Sept. 10, 1914.]

E Widmanstätten structure is not peculiar to iron and n alloys, but may occur in any metal or alloy which crystallises in the regular system and in which the solid solution is subject to recrystallisation after solidification. —W. E. F. P.

Nickel oxide ; Emissivity of —— in the range 600°—1300° *C.* G. K. Burgess and P. D. Foote. J. Franklin Inst., 1914, **178**, 233—234.

DETERMINATIONS of the monochromatic and total emissivity were made by the microscopic melt and spectrophotometer comparison methods. The monochromatic emissivity increased linearly with increasing wave length and decreased linearly with increasing temperature from 700° to 1300° C. The total emissivity increased with the temperature, being 0·54 at 600°, 0·68 at 800°, 0·76 at 1000°, 0·85 at 1200°, and 0·87 at 1300° C.: the relation is not linear.—W. R. S.

PATENTS.

Iron ; Deposition of ——. S. O. Cowper-Coles, London. Eng. Pat. 12,683, May 31, 1913.

To prevent exfoliation and brittleness of the deposit, the electrolyte (*e.g.*, a solution of ferrous sulphate) is vigorously agitated with spongy iron during electrolysis.—W. E. F. P.

Iron and iron alloys ; Hot working ——. R. B. Carnahan, jun., Middletown, Ohio, U.S.A. Eng. Pat. 28,593, Dec. 11, 1913. Addition to Eng. Pat. 28,571, Jan. 16, 1913.

THE process described in U.S. Pat. 1,090,115 (this J., 1914, 424) is extended to include the treatment of iron and iron alloys which, though not pure, are substantially free from carbon, manganese, and oxygen.—T. F. B.

Iron ; Process of casting —— in permanent moulds. E. A. Custer, Assignor to Custer Sandless Casting Co., Philadelphia, Pa. U.S. Pat. 1,104,037, July 21, 1914; date of appl., Oct. 22, 1910.

THE metal is caused to set as it is poured, and the casting is removed from the mould before chilling; the temperature of the mould (which has a relatively large mass, and superficial area) is kept below 600° F. (316° C.).—W. E. F.P.

Iron alloy. J. R. Speer, Trappe, Md. U.S. Pat. 1,105,341, July 28, 1914; date of appl., Feb. 24, 1914.

THE alloy contains Si 0·1—3, Cr 0·5—1·5, Ni 0·25—1, S 0·05—0·2, P 0·12—1·5, Mn 0·45—1, and C 1—4%, the quantity of chromium being in excess of that of nickel. —W. R. S.

[Iron-nickel] Balance spring having elasticity increasing with a rise in temperature. C. E. Guillaume, Sèvres, France, Assignor to Soc. des Fabriques de Spiraux Réunies, La Chaux-de-Fonds, Switzerland. U.S. Pats. 1,106,206 and 1,106,207, Aug. 4, 1914; date of appl., Feb. 20, 1912.

AN iron alloy containing Ni 27—31, Cr 0·2—4, V 0·2—4, and small quantities of C and Si, with or without Mn 1—4%; the constituents other than iron and nickel amount together to between 3·5 and 10%.—W. E. F. P.

Iron or steel structures ; Method of preventing corrosion on ships' bottoms and other ——. A. C. A. Holzapfel, London. Eng. Pat. 24,570, Oct. 29, 1913.

THE metal is thinly coated with a mixture of a highly volatile spirit or hydrocarbon and slaked or unslaked lime, which, when dry, is immediately replaced by a coating of paint or composition.—W. E. F. P.

Steel or iron sheets ; Method of oxidising ——. J. E. Carnahan, Canton, Ohio. U.S. Pat. 1,105,251, July 28, 1914; date of appl., June 9, 1913.

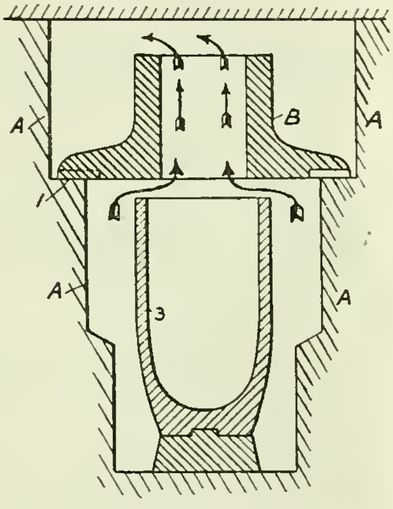
THE sheets are first "blued" by an oxidising process, then heated to dark redness and cooled in an annealing box in the presence of steam.—W. R. S.

Furnaces ; Gas heated [crucible] ——. J. King, J. R. Burnett, and The Richmond Gas Stove and Meter Co., Ltd., Warrington. Eng. Pat. 16,871, July 23, 1913.

In gas-heated crucible furnaces the heated products of combustion pass from the combustion chamber or chambers round the upper part of the crucible or pot and thence through a chamber below the crucible support to the exit flue. One or more inclined flues or passages are provided through which any metal or other material which may be spilled from the crucible is withdrawn.—W. H. C.

Furnace for melting metals. T. Ratcliff, Birmingham, and W. Ratcliff, Solihull, Warwick. Eng. Pat. 22,657, Oct. 8, 1913.

A crucible-furnace (fig.) in which a flanged tube or funnel, B, is disposed above the crucible, 3, within the heating chamber, A. The crucible is charged through the tube, the latter serving for preheating the metal and deflecting the flame upon the top of the crucible.
—W. E. F. P.



Roasting furnaces [for pyrites and other ores] ; Feeding devices for ——. H. H. Stout, New York. Eng. Pat. 3581, Feb. 11, 1914. Under Int. Conv., March 7, 1913.

In a furnace of the superposed-chamber type having feeding devices for automatically delivering ore to the drying hearth (roof) and the top chamber in succession, the effective area of the table upon which the ore is discharged from the hopper of the primary feeder is adjustable. The hopper of the secondary feeder, which surrounds and rotates with, the central shaft of the furnace, has a delivery spout from which the dried ore is discharged at an adjustable height above the floor of the top chamber.
—W. E. F. P.

Roasting furnaces ; Rabble shafts for ——. E. J. Fowler, San Francisco. Eng. Pat. 7471, March 24, 1914. Under Int. Conv., March 24, 1913.

In a rabble shaft (for roasting furnaces of the superposed-chamber type), the cylindrical wall which separates the axial from the annular passage is composed of telescopic sections ; or the outer wall is composed of abutting sections.—W. E. F. P.

Furnace ; Metallurgical ——. J. E. Greenawalt, Denver, Colo. U.S. Pat. 1,103,196, July 14, 1914 ; date of appl., Oct. 10, 1912.

The furnace consists of a hollow, movable, upper section having openings at the top and sides for the admission of air and gas respectively, and a fixed, lower section having a perforated support for the charge at the top and forming, when the upper section is placed upon it, a sealed chamber with which a suction apparatus is connected.—W. E. F. P.

Furnace ; Electric ——. H. F. D. Schwahn, Belleville, Ill. U.S. Pat. 1,105,538, July 28, 1914 ; date of appl., Sept. 26, 1912.

The smelting and refining furnace is divided, by a horizontal false bottom, into a lower chamber or well, and an upper chamber. A resister of carbonaceous material, in contact with carbon electrodes, is placed between refractory "checkers" and rests upon the false bottom. Means are provided for maintaining the material of the resister, for charging the furnace with raw material and reducing gases, and for the withdrawal of the resulting product and spent gases. The resister is not in direct contact with the unfused charge, but permits the passage of the gases and the fused non-volatile and volatile metals into the well. The latter is provided with a heating arrangement, and has a series of condensers attached to it.—B. N.

Furnace-process ; Electric —— *and electric furnace.* C. Hering, Philadelphia, Pa. U.S. Pat. 1,105,656, Aug. 4, 1914 ; date of appl., July 15, 1911.

A mass of molten metal is treated in an electric furnace by passing an electric current through a portion of the mass, disposed between masses of conducting fluid, the whole comprising a circulatory system. The current is also passed through the metal in a channel or tube, forming a conductor, disposed at an angle with the longitudina extent of the fluid metal, whereby the metal is automaticall circulated by the force exerted by the current in th conductor.—B. N.

Metals ; Precipitation of ——*from solutions of their salts an apparatus therefor.* G. Jacquier, Johannesburg, Transvaal. Eng. Pat. 17,790, Aug. 2, 1913.

Metals are precipitated from solutions of their salts b aluminium, with the aid of artificial ultra-violet radiation either alone or in combination with similar radiations fro the sun. For this purpose, mercury vapour electric lamp may be used, with containers of quartz or other materia permeable to ultra-violet rays, the lamps being suspende between the sheets of aluminium from a common supportin means.—B. N.

Ores ; Method of and means for separating metalliferou materials or metals from their —— *or other matter carryi same.* J. D. Wolf, London. Eng. Pat. 18,351, Aug. 1 1913.

A shaking table, the top of which consists of an endle belt of " woven hard duck " prepared by soaking in linse oil. The surface of the belt is dressed periodically wit a mineral oil in such quantity that no appreciable amou is retained by the surface.—W. E. F. P.

Ore ; Separation of ——. E. Primosigh, Also-Szalan Hungary. Eng. Pat. 18,944, Aug. 20, 1913.

A mixture of the ore with water, oil and acid, is introduc continuously into a closed mixing apparatus from whi air is excluded, and the materials are intimately mix by a rapid circular movement produced by a centrifug pump, the latter at the same time producing a pressu which is used for transferring the mixture through conduit to the separating bath. The pump is located this conduit, the socket of the pump through which t material is introduced being led through a water tank, a provided with one or more openings below the water lev The conduit on the delivery side of the pump is fitted wi one or more gas channels, so that compressed air or g may be supplied continuously to the mixture, thus assisti in the mixing. The end of the delivery conduit is provid with a spraying nozzle opening below the level of t liquid in the separating bath, thus producing a thorou mixing of the material by a sudden modification in t locity of the flow from the end of the delivery conduit, low the level of the contents of the separating bath. —B. N.

es ; Process of dressing —— by means of gas. K. Takeda, Tokyo, Japan. Eng. Pat. 20,158, Sept. 6, 1913. Addition to Eng. Pat. 7272, Mar. 27, 1913. (See Fr. Pat. 455,430 of 1913 : this J., 1913, 949).

E ore is moistened with water before admixture with l and alkali carbonate.—W. E. F. P.

pper ; Art of extracting ——. G. B. Chittenden, Chilito, Ariz. U.S. Pat. 1,104,410, July 21, 1914 ; date of appl., May 21, 1914.

PPER ore is leached with acid, the solution is treated th an excess of lime water, and the precipitate is subcted to a moderate heat.—W. E. F. P.

senic or antimony ; Extraction of —— from ores. F. G. Price, Assignor to H. A. Lewis, Oruro, Bolivia. U.S. Pat. 1,104,810, July 28, 1914 ; date of appl., March 8, 1912.

E ore is fused with sulphur and an alkali sulphide, and e product leached.—W. R. S.

es ; Treatment of ——. C. Robinson, Mount Vernon, N.Y., Assignor to Metallurgical Engineering and Process Corporation, New York. U.S. Pat. 1,105,102, July 28, 1914 ; date of appl., Nov. 29, 1910.

E ore is treated with a solvent which dissolves part of e metallic values ; the solution is then run off, and the e mass broken up by directing upon it a stream of the me, or another solvent, so as to expose fresh surfaces. —W. R. S.

ctroplating and the like ; Apparatus for ——. A. Murphy, Quincy, Mass. U.S. Pat. 1,105,292, July 28, 1914 ; date of appl., Oct. 22, 1913.

CYLINDRICAL inner perforated vessel is located within outer vessel, open at the top, and the latter may be tated by suitable means. Guiding pieces are attached one of the vessels and grooved strips to the other, that they may be connected and revolved together, d so that the inner vessel during removal is guided rough the open top of the outer vessel. A cathode d anode, each connected with a conducting ring, are aced respectively within the inner and outer vessels, d the cathode may be removed without disturbing e inner vessel.—B. N.

es ; Reduction of —— by means of peat. P. Anderson, Arvika, and E. E. son Odelstierna, Stocksund, Sweden. U.S. Pat. 1,105,870, Aug. 4, 1914 ; date of appl., April 18, 1912.

MIXTURE of the ore with powdered peat is heated in sed receptacles, reduction being effected without sion.—W. E. F. P.

loy. P. R. Parsons, London, and O. Silberrad, Buckhurst Hill. U.S. Pat. 1,106,055, Aug. 4, 1914 ; date of appl., March 25, 1910.

AIM is made for a high-speed ship's propeller in which least the surface exposed to erosive action consists of a -Zn alloy, of β structure, containing Cu 49—58%. —W. E. F. P.

ss ; Method of pickling ——. R. R. Parish, Assignor to Chase Rolling Mill Co., Waterbury, Conn. U.S. Pat. 1,106,107, Aug. 4, 1914 ; date of appl., Jan. 12, 1914.

SOLUTION of sulphuric acid "reinforced by a perid" is employed for removing blotches from the surface annealed brass.—W. E. F. P.

t-iron ; Process of treating ——. J. E. Johnson, jun., New York. U.S. Pat. 1,106,817, Aug. 11, 1914 ; date of appl., Aug. 13, 1913.

E Fr. Pat. 464,208 of 1913 ; this J., 1914, 488.—T. F. B.

Iron ; Treatment of ——. A. V. Dismore. Fr. Pat. 468,612, Feb. 18, 1914. Under Int. Conv., Feb. 19, 1913.

SEE Eng. Pat. 4292 of 1913 ; this J., 1911, 697.—T. F. B.

Aluminium ; Process for producing a coating on —— which is proof against the action of sea water and acids or alkalis. Z. D'Amico, Genoa, Italy. Eng. Pat. 28,410, Dec. 9, 1913. Under Int. Conv., Dec. 9, 1912. Addition to Eng. Pat. 22,684, Sept. 30, 1910.

SEE Ger. Pat. 273,292 of 1912 ; this J., 1914, 700.—T.F.B.

Alkali metals ; Electrolytic manufacture of ——. E. A. Ashcroft, London. U.S. Pat. 1,106,436, Aug. 11, 1914 ; date of appl., May 23, 1914.

SEE Eng. Pat. 10,980 of 1914 ; this J., 1914, 794.—T. F. B.

Sodium ; Process and apparatus for the [electrolytic] manufacture of ——. E. Marguet. Fr. Pat. 467,991, April 9, 1913.

SEE Eng. Pat. 11,278 of 1913 ; this J., 1914, 359.—T. F. B.

Open-hearth furnaces ; Regenerative ——. T. B. Rogerson. Fr. Pat. 468,451, Feb. 14, 1914. Under Int. Conv., May 8, 1913.

SEE Eng. Pat. 10,853 of 1913 ; this J., 1913, 1116.—T.F.B.

PATENT CASE.

Mineral substances ; Separation of —— by the selective action of oil. A. S. Elmore, London. Eng. Pat. 6519 of 1901 ; this J., 1902, 349. Reports of Patent Cases, Vol. XXXI. Illus. Off. Jnl. (Patents) Suppl., May 6, 1914. By permission.

THIS was an appeal to the Judicial Committee of the Privy Council from a decision of the Supreme Court of New South Wales, dismissing an action for infringement of the corresponding N.S.W. patent brought by the Ore Concentration Co. (1905), Ltd., against the Sulphide Corporation, Ltd. In a similar action in respect of the above Eng. Pat., the House of Lords had already decided that the patent had not been infringed.

The first of the five claims in the specification was as follows : In processes for separating metals by the selective action of oil, the addition of a small quantity of acid to the oil or water employed in the process, or to both, substantially as and for the purpose set forth. The appellants contended that the expression "the selective action of oil" was referable only to conditions in which the oil had a choice between mineral and gangue, and that those conditions existed only in a freely-flowing pulp. The respondents contended that the expression was referable only to conditions in which the oil was capable of carrying the particles in the process of separation, whether by buoyancy or in the form of oil globules. They also stated that they used, not a large quantity of thick oil, as the appellants did, but a small quantity of thin oil and that their process depended on surface tension. The Judicial Committee held that, as to the construction of the specification, the respondents' contention was well founded and that the invention claimed was the enhancement of the action of oil, as a selective agent, by the addition of a small quantity of acid to the oil or water in any process of separation in which the oil was adequate in quantity and of sufficient tenacity to entrap or coat mineral particles in a watery pulp, and to hold or carry them until separation was effected ; and that there was no limitation to the two forms of apparatus described in the specification ; that the invention was novel and useful ; but that the respondents used a process essentially distinct from that claimed and that there was no infringement. The small quantity of oil introduced in the respondents' process did not necessarily perform any other function than to give permanency in the froth and extremely minute emulsion. There might be oil in excess, and some of the particles might get oiled, but this was unessential. That process could be accounted for without assuming selection of the metallic particles by oil.

XI.—ELECTRO-CHEMISTRY.

Stability and oxidation-potential of hypochlorites. Contribution to catalysis, and a hypochlorite-carbon cell. Hofmann and Ritter. *See* VII.

Patents.

Cell; Galvanic ——. P. Burger, Berlin. Eng. Pat. 15,463, July 4, 1913. Under Int. Conv., July 6, 1912.

The carbon electrode is surrounded by "brownstone," mixed with chemically pure carbon, obtained in the form of soot from acetylene gas, in place of graphite.—B. N.

Containers or diaphragms for voltaic cells; Porous ——. J. G. Lucas, London. Eng. Pat. 24,569, Oct. 29, 1913.

The vessel, in the form of a basket adapted to hold the granular or pulverised particles of the depolariser, is constructed by plaiting Japanese rush in horizontal circular coils, strengthened by vertical lacing of the same material. —B. N.

Accumulators; Electric ——. A. Dinin, Paris. Eng. Pat. 14,119, June 11, 1914.

The negative electrodes of accumulators may be kept in a dry charged condition in the open air, by dehydrating the electrodes out of contact with the air. This may be effected by drying in a vacuum, or by treating the charged electrode with a volatile substance, such as alcohol.—B. N.

Battery plates: Apparatus for, and process of treating ——. G. H. Rabenalt, Buffalo, N.Y., Assignor to Gould Storage Battery Co., New York. U.S. Pats. (A) 1,104,272, and (B) 1,104,273, July 21, 1914; date of appl., Feb. 6, 1913.

(A.) One face of a containing vessel is provided with an acid-proof porous die, the latter having a roughened face so that when applied to a pasted battery plate the active area is increased, and the upper part of the container is connected with a vessel supplying a reagent under pressure, so that when this is passed through the pores of the die the paste is hardened. Both sides of a pasted battery plate may be thus similarly and simultaneously treated. (B.) Sulphuric acid may be used as the reagent so as to form a sulphate on the surface of the paste, thus hardening the latter before the die is removed.—B. N.

Electrodes; Storage battery ——. H. C. Hubbell, Newark, N.J. U.S. Pat. 1,104,898, July 28, 1914; date of appl., Nov. 18, 1912.

Precipitated active material, without drying, is kneaded into a slime with water, and the slime mixed with suitable conducting elements, dried to a thick dough, formed into cakes, dried, and strongly compressed edgewise. —B. N.

Cell; Electrolytic ——. J. B. Burdett, Assignor to Davis-Bournonville Co., Chicago, Ill. U.S. Pat. 1,104,754, July 21, 1914; date of appl., Nov. 6, 1912.

The cell is provided with a cover having integral walls arranged spirally upon its under surface, thus forming a closed chamber with an open space between the spiral convolutions. Electrode plates, similarly formed into spirals, are suspended in the chamber and the open space. A porous curtain, applied against the spiral wall of the chamber and depending therefrom in spiral formation, is interposed between the electrode plates. The curtain is secured against the spiral wall by a clamping ring, the latter being provided with an "off-set lower edge" engaging over the lower edge of the wall, in order to bring the surface of the curtain into alignment with the inner surface of the wall. Gas-delivery connections communicate with the chamber and the exterior space.—B. N.

Cell; Electrolytic ——. D. B. Ayerst, Wilmington, Del. U.S. Pat. 1,105,015, July 28, 1914; date of appl., Feb. 24, 1913.

The cell, for the electrolysis of saline solutions, comprises a body constituting an anode chamber, with diaphragms closing the sides; cathodes are disposed outside the diaphragms and anodes within the chamber confronting the diaphragms. A salt receptacle within the body is immersed in the electrolyte, and valved, perforated pipes are located respectively between the anodes, and between each anode and its confronting diaphragm for delivering air into the electrolyte.—B. N.

Resistance; Artificial [electrical] ——. G. J. Gage, Hillyard, Wash., Assignor to Gage Electric Co., Spokane, Wash. U.S. Pat. 1,105,070, July 28, 1914; date of appl., March 31, 1913.

One part by weight of finely divided graphite and sever of carborundum are bound together by an alkali silicat into a coherent and compact form, which is moulded b pressure and heat; the latter liberates silica which act as the effective binding agent. The resistance is provided on one or more sides, with a heat-insulating coating, which is united integrally with it.—B. N.

Furnace; Rotary electric ——. A. S. Bemis, Assignor t National Carbon Co., Cleveland, Ohio. U.S. Pat 1,105,175, July 28, 1914; date of appl., Jan. 22, 1912.

Granular material is fed through a hollow electrode o to a lower electrode, which is rotated about a vertical axis and a current is passed through the peak of the pile which is formed in the hollow electrode. The current is transmitted from the material to the rotating electrode, and a the same time the charge is moved substantially at righ angles to its perpendicular axis and to the general directio of the current flow.—B. N.

Electric furnace [for manufacture of stable boron nitride Comp. Franç. pour l'Exploitation des Procédés Thomson Houston. First Addition, dated Feb. 2, 1914, to F Pat. 456,488, April 10, 1913. Under Int. Conv., Feb. 1913.

Treatment of seed grain. U.S. Pat. 1,106,039. *See* XIX

XII.—FATS; OILS; WAXES.

Fats; Natural —— from the standpoint of the phase-ru II. The ternary system: tripalmitin, stearic and palmi acids. R. Kremann and H. Klein. Monats. Chem 1913, **34**, 1291—1311.

In the binary systems composed of tripalmitin wi stearic acid and with palmitic acid, no compounds or so solutions are formed but only simple eutectics containi respectively somewhat more than 60% and about 50 of tripalmitin and melting at 58° and at 54° C. The otl binary system, composed of stearic and palmitic aci has been studied by de Visser (this J., 1898, 853) and Carlinfanti and Levi-Malvano (this J., 1909, 131 according to the latter authors the two acids form addition-compound, $C_{18}H_{36}O_2,C_{16}H_{32}O_2$, and this for a continuous series of solid solutions with stearic a and three different series of solid solutions with palmi acid. In studying the ternary system series of mixtu were prepared in which two of the components w in a constant ratio and the proportion of the third vari. The results are given in tables and curves, including triangular diagram. The eutectic line in the triangu diagram passes through a minimum at 49° C. but ma of the mixtures solidify at considerably lower temperat owing to undercooling.—A. S.

ats : *Natural —— from the standpoint of the phase-rule III. The ternary system : tristearin, stearic and palmitic acids.* R. Kremann and R. Kropsch. Monats. Chem., 1914, **35**, 561—580. (See also this J., 1912, 1040).

Ir the three binary systems mixtures of stearic nd palmitic acids have been studied by de 'isser (this J., 1898, 853) and by Levi-Malvano (this J., 909, 1318). In mixtures of tristearin and stearic acid ne solidifying point falls from that of stearic acid (67·5° C.) o an eutectic point (about 54° C., 90% of tristearin) and hen rises to the solidifying point of tristearin (56° C.). he system tristearin-palmitic acid is more complicated. he curve rises steeply from the solidifying point of tri- earin, passes through a flat maximum at about 7% of almitic acid, shows an ill-defined eutectic point (63° C.) t about 16%, a second very flat maximum, another itectic point (55° C.) at about 50% of palmitic acid nd then rises to the solidifying point of palmitic acid. 'wo compounds containing respectively 4 mols. and 1 mol. f tristearin to 1 mol. of palmitic acid, are probably formed, nd the eutectic point of mixtures of the former and tri- earin practically coincides with the solidifying point of istearin. An eutectic arrest was never observed with ixtures containing from 50 to 100% of palmitic acid and is possible that solid solutions are formed in this portion f the system. In studying the ternary system, series of ixtures were examined in which the relative proportions f two of the components were kept constant and that of ne third varied. The results are given in a series of bles and curves, including a triangular curve-diagram. n all the ternary mixtures complete solidification occurred ithin the temperature range 51°—54° C. The results iow that in hardened fats, *i.e.*, fats free from oleic acid nd olein, the highest melting-points will be obtained with ixtures of tristearin and palmitic acid, especially when ne content of the latter is small : addition of increasing uantities of stearic acid causes a tolerably rapid fall of ne primary solidifying point.—A. S.

ats ; *Catalytic hydrogenation of ——.* E. Bontoux. Les Matières Grasses, 1914, **7**, 4194—4198.

YDROGEN for hydrogenating fats must be free from lorine, sulphur, arsenic and phosphorus, and as ee as possible from oxygen and oxides of carbon. lectrolysis of alkaline distilled water by various methods used in some of the larger works (Siemens-Schuckert, teliers Oerlikon) to obtain very pure hydrogen which ntains as impurity only 0·2% oxygen. The electric ower consumed is 6 kilowatt-hours per cb.m. of hydrogen. n other works the hydrogen is prepared from water-gas producer-gas. The methods of Linde-Frank-Caro nd of the Soc. de l'Air Liquide are based on the fractional stillation of the liquefied components of water-gas, the ydrogen thus obtained being of 97 to 98% purity, and it is rought to 99 to 99·5% by being passed over soda-lime 180° C. In Lane's method steam is decomposed by d-hot iron, and the resulting iron oxide is reduced by the ements of water-gas. The Soc. Lyonnaise du Gaz use asted pyrites, and the Griesheim Elektron Co. employ a ixture of lime and iron to decompose the gas. These ethods yield a gas of 97·5 to 98·5% purity. In countries ith a petroleum supply the method of Rincker-Wolter n which the hydrocarbons of oil-gas are decomposed at high temperature into carbon and hydrogen) is used. n installation for the production of electrolytic hydrogen sts about 110,000 francs (about £4,400) for 45 cb.m. 590 cb. ft.) per hour, and about 230,000 fr. (about £9100) r 100 cb.m. (3530 cb. ft.). With electric power at 3 ntimes (0·3d.) per kilowatt-hour the gas will cost about 3 centimes per cb.m. (about 6s. 3½d. per 1000 cb. ft.), cluding labour. An installation for water-gas costs ther more than 200,000 francs (about £7900) for 50 cb.m. d 300,000 francs (about £11,900) per 100 cb.m. per hour, it the gas will cost only 10 to 15 centimes per cb.m. s. 3d.—3s. 4½d. per 1000 cb. ft.). A complete plant for drogenating less than 15 metric tons a day costs from 0,000 to 400,000 francs (about £13,900—£15,900), and e cost of hardening 100 kilos. of fat ranges from 3 to 8 ancs (1s. 2½d.—3s. 2½d. per cwt.) according to the process, e nature of the initial oil, and whether the hydrogenated t is intended for technical or edible purposes.—C. A. M.

Oxycholesterol and its digitonin compound. J. Lifschutz and T. Grethe. Ber., 1914, **47**, 1453—1459.

OXYCHOLESTEROL, $C_{27}H_{46}O_2$ or $C_{28}H_{44}O_2$, occurs in animal fats in association with cholesterol and may be prepared by oxidising cholesterol with benzoyl peroxide and purifying the product by treatment with methyl alcohol. It is a light yellow amorphous substance which resembles colophony and becomes electrified when rubbed. It softens at 100° C. and is completely fluid at 107°—113° C. It is soluble in all ordinary solvents and forms a colloidal solution in water. It gives all the ordinary reactions of cholesterol, but may be distinguished therefrom, by treating its solution in glacial acetic acid with a few drops of concentrated sulphuric acid. The red or bluish-violet colour thus produced is changed to bright green on adding ferric chloride solution, and on then adding one or two drops of chromic acid the liquid becomes colourless. Cholesterol does not give this colour reaction. Oxycholesterol is precipitated by an alcoholic solution of digitonin, the digitonide crystallising in rhombic plates which melt at 215° to 218° C. It forms a colloidal solution in water, dissolves with difficulty in chloroform, and is almost insoluble in ether and hydrocarbons.—C. A. M.

Enzyme action ; Studies on ——. XXII. Lipase. IV. Correlation of synthetic and hydrolytic activity. H. E. Armstrong and H. W. Gosney. Roy. Soc. Proc., 1914, B **88**, 176—189.

IN a previous communication (this J., 1913, 917) it was concluded from experimental results that lipase was specially fitted to act on oily glycerides but not to act in aqueous solutions, and that probably interaction takes place at and between surfaces separated only by a thin film of water at most. Parallel series of experiments have now been made on the influence of water and glycerol on the synthesis of glycerides from the fatty acids of olive oil and glycerol and the hydrolysis of olive oil. Using proportions of fatty acids and glycerol necessary for the formation of a triglyceride, equilibrium was attained when about 40% of acid was combined, and similar results were obtained for the hydrolysis of olive oil in presence of the theoretical minimum quantity of water. By addition of water the equilibrium was displaced in the direction of greater hydrolysis and the rate of change was markedly retarded. Excess of glycerol also retarded the rate of change and displaced the equilibrium in the opposite direction ; for example, with equivalent proportions of fatty acids and glycerol 39·2% of acid was combined in 50 hours, whilst with 1 mol. excess of glycerol, 55·8% of acid was combined. The retardation of hydrolysis by water is ascribed to its direct action in preventing effective contact of the enzyme and oil, but its effect in the synthetic experiments, especially the diminution of the extent to which synthesis takes place, is probably due to withdrawal of glycerol from the system through its solution in the water : synthesis was not entirely prevented even by 30 mols. of water to 1 mol. of glycerol, but in absence of excess of water, excess of glycerol beyond 2 mols. had but little effect in increasing the proportion of fat synthesised. The enzyme may be rendered inert by "overdrying," becoming active again on addition of a very small quantity of water. Enzyme which has been used and then recovered by washing with light petroleum, is usually less active than it was originally, the hydrolytic activity—in presence of a relatively large excess of water—being more affected than the synthetic activity. In one experiment with the fatty acids of olive oil and excess of glycerol, the reaction product was isolated by adding alcohol, neutralising the unchanged acid with caustic soda, evaporating off the alcohol, and extracting the soap solution with ether. About 18 grms. of a pale yellow oil was obtained having the saponif. value 183·5 (saponif. value of original olive oil, 191·7) and acetyl value 78·6. This result and others also cited indicate that mono- and di-glycerides are formed.

Bournot's statement (this J., 1913, 758) that the lipase of *Chelidonium majus* seeds does not require treatment with acid to render it active is confirmed. According to Bournot *Chelidonium* lipase differs from *Ricinus* lipase in being most active in a neutral medium, but the authors point out that *Ricinus* lipase, when once liberated from its zymogen, is also sensitive to acid, exhibiting maximum activity when the acidity does not exceed that of oleic acid. The enzymes from the two sources gave similar results in the synthesis and hydrolysis of triolein, but, weight for weight, the *Chelidonium* lipase was more active than *Ricinus* lipase in effecting the synthesis and hydrolysis of isobutyl oleate.—A. S.

Glycerin in the United States. Oil, Paint and Drug Rept., Aug. 31, 1914. [T.R.]

THE destruction by fire on August 23rd of the large new glycerin refining plant of Wm. F. Jobbins, Inc, at Aurora, Ill., and the shutting off of foreign supplies of the crude product have combined to raise prices in all grades. Fully 1,000,000 lb. of dynamite glycerin were destroyed in the fire, and should the directors decide to rebuild, it will take a year to do so. As the United States produces less than half of the world's requirements of glycerin suitable for refining into the C.P. grade and as no crude glycerin is now obtainable from Europe, a noteworthy shortage of supplies is expected for the remainder of this year. There are only three U.S. refineries left, viz., those of the Du Pont Powder Company, which makes refined dynamite glycerin for its own consumption at Repauno, N.J.; Marx and Rawolle, with a plant in Brooklyn, and the Harshaw, Fuller and Goodwin Company, with a plant in Elyria, near Cleveland, Ohio.

PATENTS.

Oils from solids; Process for extracting ——. C. Turner, Chicago, Ill. U.S. Pat. 1,104,456, July 21, 1914; date of appl., June 26, 1911.

THE solid material is washed with a volatile solvent as it passes through one or more inclined chambers; the liquid is drained off laterally into a separation tank, while the residue is discharged through a liquid seal into a chamber, where the remaining solvent is evaporated, escape of vapours through the receiving and discharging openings of the chamber being prevented by directing into them a vapour under pressure.—C. A. M.

Oils; Treatment of ——. B. Lach, Vienna. U.S. Pat. 1,104,906, July 28, 1914; date of appl., June 5, 1913.

OILS are purified by treating them with steam after the addition of a quantity of formaldehyde sufficient to precipitate any proteins present. The excess of formaldehyde is then removed by means of nascent hydrogen produced by adding an acid and a metal to the oil.—W. P. S.

Cottonseed oil; Process of bleaching ——. C. Baskerville. New York. U.S. Pat. 1,105,743, Aug. 4, 1914; date of appl., Jan. 24, 1913.

VEGETABLE oils, such as cottonseed oil, containing colloidal colouring matter, are agitated, below 100° C., with an inorganic absorbent having the properties of fuller's earth, the treatment being carried out in the presence of an electrolyte and under conditions suitable to the coagulation of the colouring matter.—W. P. S.

Oils; Process of refining vegetable and animal ——. C. Baskerville, New York. U.S. Pat. 1,105,744, Aug. 4, 1914; date of appl., Feb. 15, 1913.

OILS and fats containing free acids are agitated with a fibrous vegetable material impregnated with a quantity of alkali slightly in excess of that required to neutralise the acids, and are then filtered.—W. P. S

Sulphonated stearic products; Production and utilisation of ——. I. Levinstein, Manchester. Eng. Pat. 16,577, July 19, 1913.

PURE or commercial stearic acid is melted with a fat capable of sulphonation (*e.g.*, stearine, wool stearine, palm oil), the mixture sulphonated at, say, 35° to 45° C., the sulphonated product washed, and the mineral acid separated or neutralised. Concurrent sulphonation of the stearic acid is thus effected. Miscible or emulsifiable preparations are obtained by mixing the sulphonated products with oils, waxes or greases.—C. A. M.

Beeswax; Process of bleaching ——. G. F. Jehlicka Williamsville, Mass. U.S. Pat. 1,106,221, Aug. 4. 1914; date of appl., Oct. 15, 1912.

BEESWAX is melted by the direct action of steam, allowed to settle, and the clear wax transferred to a bath consisting of 21 oz. of iron-free sulphuric acid and 1 lb. of sodium peroxide dissolved in 12 galls. of water, this solution being rendered slightly alkaline by the addition of a small quantity of sodium silicate; the bath is heated to 160° F (71° C.) by the injection of steam, and the wax and solution are agitated by blowing in air. The bleached wax is transferred to a vessel containing slightly acidified cold water the latter is heated to boiling for a definite period, and the wax is drawn off, and re-melted.—W. P. S.

Oleic and fatty acids derived from train or fish oils; Proces for deodorising ——. W. H. Hofmann, Hamburg, Germany. U.S. Pat. 1,106,509, Aug. 11, 1914. Date o appl., Sept. 23, 1913.

SEE Fr. Pat. 462,763 of 1913; this J., 1914, 324.—T. F. B

Emulsion products and process for producing them. I Berend, Assignor to Dr. Kurt Albert Chem. Fabrik Amöneburg on Rhine, Germany. U.S. Pat. 1,107,02 Aug. 11, 1913. Date of appl., Feb. 26, 1912.

XIII.—PAINTS; PIGMENTS; VARNISHES; RESINS.

Resins, etc., used in embalming in Egypt and Carthag 2000—800 B.C. L. Reutter. Chem.-Zeit., 1914, 3 276.

IN a specimen examined by the author were found: masti resin of *Pinus halepensis*, storax, asphaltum, resin cedar, residues of conifers such as *Juniperus oxycedru* wine residues, sodium carbonate, sulphate and chlorid together with different stones and pearls.—J. B.

Recovery of volatile solvents used in the manufacture of plast materials [*artificial silk, etc.*]. Barthélemy. *See* V.

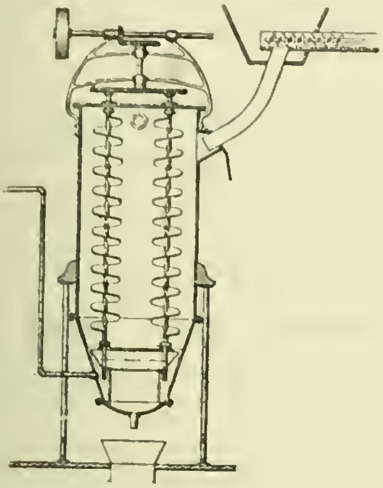
PATENTS.

Rosin from resinous wood; Method of extracting — F. E. Lichtenthaeler, Newton, Mass. U.S. Pa 1,104,912, July 28, 1914; date of appl., Mar. 17, 1913

RESINOUS wood is treated with steam at 250° C., t pressure in the vessel being reduced to about 2 lb. per sq. i (absolute), and the vaporous mixture of rosin and stea is led to a condenser.—W. P. S.

Turpentine-extractor. J. M. Hillard, Gulfport, Mis Assignor to M. W. Connor, Columbia, Miss. U.S. Pa 1,103,878, July 14, 1914; date of appl., Jan. 11, 191

THE extractor consists of a retort having, at the upp end, a vapour outlet, and at the lower end door for discharging the refuse, and, above t door, an arrangement of screens which serves a steam-chest from which two hollow vertical sha re supplied. The shafts are provided with steam-ischarge ports at intervals, and with spiral agitator lades, and are arranged to rotate in such a way that ne imparts an upward and the other a downward motion the material in the extractor. The heavier by-products e discharged through an outlet in the door.—E. W. L.



esinous condensation products. The British Thomson-Houston Co., Ltd., London. From General Electric Co., Schenectady, U.S.A. Eng. Pat. 22,421, Oct. 4, 1913. Addition to Eng. Pat. 24,254, Oct. 23, 1912 (this J., 1914, 92).

ESINOUS products of the type described in the previous atent (*loc. cit.*) are obtained by heating a mixture in uimolecular proportions of glycerol and phthalic acid or nhydride, adding to the resulting compound 0·25 mol. roportion of phthalic anhydride and 0·5 mol. proportion oleic acid, and completing the reaction. The resinous mpound, which may be hardened by heating it to 0° C., is suitable for insulating purposes or for varnishes, d may be used for impregnating paper, wood, textile brics, etc.—C. A. M.

acking material; Acid-proof —— M. L. Chappell, Berkeley, Cal. U.S. Pat. 1,102,473, July 7, 1914; date of appl., Sept. 9, 1913.

HE packing material contains a condensation product of henol, formaldehyde, an unsaturated fatty acid such as eic acid and a condensing agent consisting of an alkali mmonium) salt of the acid. A lubricant may be added. —E. W. L.

omposition [resin] and process of manufacturing same. J. W. Aylsworth, Assignor to Condensite Co. of America, East Orange, N.J. U.S. Pat. 1,102,630, July 7, 1914; date of appl., May 14, 1909.

FORMALDEHYDE compound, having the formula $H_2O)_n$—where *n* is less than 4—is heated at a temperare not exceeding 350° F. (177° C.) with an anhydrous sible phenol resin, for a length of time sufficient to cause mplete hardening. The proportions of the two reacting dies are determined by ascertaining the amount of free enol in the phenol resin and calculating the amount of rmaldehyde compound necessary for complete combinan to form a hard infusible resin.—E. W. L.

astic composition [for sound records] and method of making ame. J. W. Aylsworth, Assignor to Condensite Co. of America, East Orange, N.J. U.S. Pat. 1,102,631, July 7, 1914; date of appl., Aug. 6, 1910.

HE composition is composed of a filling body, consisting a hard, infusible, final phenol-methylene condensation product (which may contain a plasticising agent), and a binder, consisting of a fusible phenol-methylene condensation product and a hardening agent, or of a fusible phenolic condensation product, hexamethylenetetramine and a plasticising agent. The mixture is heated under conditions such as will harden the mass, and, in the case of sound records, is cooled before removal from the mould. —E. W. L.

Enamel, lacquer, or varnish composition. J. W. Aylsworth, Assignor to Condensite Co. of America, Glen Ridge, N.J. U.S. Pat. 1,102,632, July 7, 1914; date of appl., July 22, 1911.

THE enamel or varnish composition consists of an anhydrous fusible phenol resin, an anhydrous hardening agent containing methylene (*e.g.*, hexamethylenetetramine) and free phenol, and a fluid thinner, all dissolved in acetylene tetrachloride.—E. W. L.

Insulating composition. J. W. Aylsworth, Assignor to Condensite Co. of America, Glen Ridge, N.J. U.S. Pat. 1,102,633, July 7, 1914; date of appl., Jan. 2, 1912.

AN insulating composition, which is slightly flexible when cold and has a congealing or setting point of 240°—320° F. (116°—160° C.) consists of Manila gum (100), phenylphthalimide (20—70) and castor oil (10—30 parts).—E. W. L.

Plastic phenolic condensation product and process for making same. J. W. Aylsworth, Assignor to Condensite Co. of America, Glen Ridge, N.J. U.S. Pat. 1,102,634, July 7, 1914; date of appl., March 18, 1912.

AN anhydrous composition, infusible, and insoluble in alcohol or water, and plastic at high temperatures, is formed when a fusible phenol resin, a methylene-containing hardening agent, and benzoic anhydride are heated together. Any water evolved combines with the anhydride.—E. W. L.

Varnish and process of making same. M. F. Conghlin, Stoughton, Mass., Assignor to F. H. Kennard, Newton Center, Mass. U.S. Pat. 1,103,266, July 14, 1914; date of appl., Feb. 2, 1914.

A SOLUTION of kino resin in alcohol of more than 70% strength is mixed with a quantity of a solution of sulphite pitch in alcohol of less than 70% strength, sufficient to produce a solution in solvent of approximately 70% strength.—E. W. L.

Composition [for varnish] containing sulphite waste and shellac. M. F. Conghlin, Stoughton, Mass., Assignor to F. H. Konnard, Newton Center, Mass. U.S. Pat. 1,103,267, July 14, 1914; date of appl., Feb. 2, 1914.

THE composition consists of an ammoniacal solution of shellac together with the solid constituents of waste sulphite liquor.—E. W. L.

XIV.—INDIA-RUBBER; GUTTA-PERCHA.

Caoutchouc solutions; Osmotic properties and physical constitution of ——. W. A. Caspari. Chem. Soc. Trans., 1914, **105**, 2139—2150. (See also this J., 1913, 1041.)

Determinations of the osmotic pressures of solutions of caoutchouc in benzene and in light petroleum (b. pt. 80°—120° C.), using ordinary white porous earthenware cells, the pores of which were blocked with cold-vulcanised caoutchouc, as semi-permeable diaphragms, showed that the osmotic rise increased more rapidly than the concentration. Solutions which had become less viscous by keeping or by boiling gave a much smaller osmotic pressure than freshly-prepared solutions of the same concentration. This is probably because a solution of caoutchouc consists of a sol- and a gel-phase. If the gel-phase is osmotically inactive the results obtained indicate that as the concentration increases, the sol-phase becomes more concentrated than the gel-phase, and as the viscosity of a given solution decreases the sol-phase diminishes. The gel-phase in contact with the diaphragm (depending on ratio of gel-volume to sol-volume in the liquid) may however exert simultaneously a pressure of the same character as that which causes caoutchouc, gelatin, etc., to swell when immersed in solvents.—T. C.

Patents.

Rubber; Method of and apparatus for coagulating ——. F. W. Manson, London. From T. W. Donaldson, Klang, Fed. Malay States. Eng. Pat. 22,302, Oct. 3, 1913.

Smoke from the combustion of carbonaceous material is passed through the latex in a closed vessel divided into two compartments communicating at the bottom. The smoke enters at the top of one compartment and leaves the other compartment through an outlet at the top, connected with a pump or fan.—C. A. M.

Rubber latex; Treatment [coagulation] of ——. W. G. ten Houte de Lange, jun., Amsterdam, Holland. Eng. Pat. 24,342, Oct. 27, 1913.

Latex enters, from a containing vessel, the top of a smoke chamber, and is delivered on to the surface of the uppermost of three superimposed rollers, through a perforated pipe. The middle roller rotates in the opposite direction to the other two, and, by means of baffle-plates, smoke from an outside generator is caused to pass, through a controlling slide-valve, upwards between and around the rollers in a direction opposite to that of their rotation. The latex is partially coagulated on the top roller; the uncoagulated portion flows downwards on to the middle roller where a further portion is coagulated; and on the third roller the remainder is coagulated. In this way a separation or grading as to quality is effected. Doors are provided for the removal of the sheet of rubber from the rollers; a vessel below the rollers for the reception of the serum; and a fan in the upper part of the chamber for the removal of smoke before opening the doors. —E. W. L.

Sponge-rubber; Method of making ——. J. Huebner, Chicago, Ill. U.S. Pat. 1,103,359, July 14, 1914; date of appl., Jan. 25, 1913.

Rubber is mixed successively, at different intervals, with resin oil, zinc oxide, turpentine, flowers of sulphur and ammonium carbonate; the mass is shaped in a mould, transferred to a vulcaniser, and steam admitted at intervals at successively higher temperatures, until a maximum of 35 lb. pressure is attained. This pressure is maintained until the mass is vulcanised.—E. W. L.

Pontianac; Process of treating ——. A. R. Ellison, Brookline, Mass. U.S. Pat. 1,104,744, July 21, 1914; date of appl., Oct. 13, 1909.

Pontianac is agitated with a mixture of naphtha, acetone oil (say, equal parts) and acetone (slightly more than one part), and the separated rubber washed with boiling water.—C. A. M.

Rubber substitute; Process for making a ——. C. Lamberty. Fr. Pat. 468,409, Feb. 13, 1914.

See Eng. Pat. 20,261 of 1912; this J., 1913, 760.—T. F. B.

Process of producing isoprene. U.S. Pat. 1,106,290. *See* XX.

XV.—LEATHER; BONE; HORN; GLUE.

Proteins [gelatin and fibrin]; Influence of certain non-electrolytes on the swelling of ——. M. H. Fischer and A. Sykes. Les Matières Grasses, 1914, **7**, 4202—4204.

Fibrin and gelatin swell more in acid solution than in distilled water, but the addition of any salt reduces the degree of swelling. With non-electrolytes the maximum dehydrating effect is attained only at high concentrations, but with electrolytes it is reached at relatively low concentrations and there is little increase in the action for each increase in the concentration. Sheets of gelatin of equal size and weight were immersed in water and in solutions of different non-electrolytes, and curves were plotted in which the times represented the abscissæ and the increases in weight the ordinates. Sucrose caused greater reduction in the swelling than lævulose or dextrose, whilst methyl, ethyl, and propyl alcohols, propylene-glycol and acetone had a dehydrating action similar to that caused by monosaccharides. In the case of fibrin the absolute degree of dehydration was less than with gelatin. At equal concentrations the effect of sugars, and especially sucrose, upon fibrin was greater than that of the alcohols.—C. A. M.

Patents.

Leather goods; Processes for washing or cleansing ——. Karplus und Herzberger, Berlin. Eng. Pat. 15,932, July 10, 1913. Under Int. Conv., July 11, 1912.

XVI.—SOILS; FERTILISERS.

Soils; Determination of the lime requirements of —— H. B. Hutchinson and K. MacLennan. Chem. News 1914, **110**, 61—62.

From 10 to 20 grms. of the soil are treated in a bottle wit 300 c.c. of approximately $N/50$ calcium bicarbonat solution, the air in the bottle is displaced by carbon dioxid and the mixture shaken for 3 hours. The solution is the filtered, and 150 c.c. of the filtrate are titrated with N/1 acid, using methyl orange as indicator. The differenc between this titration and the titre of the calciu bicarbonate solution is taken to represent the amoun of calcium carbonate absorbed by the soil. The calciu bicarbonate solution is prepared by suspending an exce of calcium carbonate in water, saturating with carbo dioxide, filtering, and diluting the filtrate with one-thir of its volume of water.—W. P. S.

Green manuring experiments, 1912–13. C. M. Hutchinson and S. Milligan. Agric. Research Inst., Pusa, India. Bull. No. 40. 1914.

Field trials and laboratory experiments were made with a green manure obtained from crops of *Crotalaria juncea* (sann hemp) in Pusa soil. The general result of the field trials was that no advantage accrued to the succeeding crop from the previous green manuring. In the laboratory experiments the optimum moisture content of the soil for nitrification was 18%, *i.e.*, with soil three-eighths saturated; under this condition 67·8% of the nitrogen of the manure was nitrified in 8 weeks. The optimum depth for burial varied with the age of the plant and also with the aeration and moisture of the soil, the more mature plant requiring to be buried nearer the surface. The biological activity of the soil was tested by the amount of carbon dioxide formed per day; the addition of the green manure increased the carbon dioxide about 10 times, and the addition of a fertiliser, such as superphosphate or bone meal, to the green manure, still further increased the evolution. Indications were obtained that the first stages of decay of the green manure were brought about mainly by fungi.—J. H. J.

Fertilisers for grapes; A test of commercial ——. U. P. Hedrick and F. E. Gladwin. New York Agric. Exp. Stat., Bull. **381**, March, 1914, 201—230.

The treatment consisted in annual applications of nitrogen in the form of sodium nitrate, dried blood and cottonseed meal, of phosphorus as acid phosphate (superphosphate), of potassium as potassium sulphate, and of lime. Nitrogenous fertilisers had a marked beneficial effect upon the yield and quality of the fruit, leaf and wood growth, whereas lime had no effect, and phosphorus and potassium so little that the use was not profitable To restore a failing vineyard, the steps required in the usual order of importance, are to secure a good drainage, control insects and fungi, improve the tillage and general care, apply such fertilisers as may be found lacking, nitrogen being probably most frequently the element needed.—B. N.

Calcium cyanamide [nitrolim]; Action of carbon dioxide on crude ——. C. Manuelli. Annali Chim. Appl., 1914, **1**, 493—494.

Some of the difficulties met with in the use of nitrolim as a fertiliser have been attributed to the presence of free lime, and it has been suggested that the latter might be converted into carbonate by substituting carbon dioxide for nitrogen in the furnace during the cooling of the nitrolim. In two experiments in which nitrolim was cooled from 800° to 480° C. in ½ hour and from 800° to 500° C. in one hour in a current of carbon dioxide, there were, however, losses of 12% and 29% respectively of the total nitrogen of the nitrolim.—A. S.

Patents.

Soil or rocks impervious; Process for making ——. A. Abraham, Liège, Belgium. Eng. Pat. 4805, Feb. 24, 1914. Under Int. Conv., Feb. 26, 1913. Addition to Eng. Pat. 10,478, May 2, 1912 (this J., 1912, 653).

Water or other inert liquid is introduced into the soil, etc. between the two reacting solutions, in order to prevent premature interaction.—C. A. M.

Fertilizers and method of preparing same. F. Hodson, Nottingham. Eng. Pat. 13,840, Nov. 20, 1913.

Lime obtained by burning limestone in a kiln is slaked with an excess of water, and the lime paste dried in a heated chamber with open top, into which steam at 20 lb. pressure is blown. The fine powder thus obtained may be applied direct or in admixture with other fertilisers. —E. W. L.

Manures. L. D. Wilson, Great Shelford, Cambs. Eng. Pats. 19,102, Aug. 22, 1913, and 2167, Jan. 27, 1914.

Manures are prepared in the "wet" or "dry" way from limestone and or one or more of the materials peat, plaster of Paris, oil-cake, wood, bone ashes, one or more salts of manganese, and sugar or molasses.—W. E. F. P.

Calcium cyanamide; Method of and apparatus for granulating ——. Eng. Pat. 15,713, July 8, 1913.

A paste of finely ground calcium cyanamide and water is fed through a hopper containing a stirring device on to the surface of a rotating, fluted cylinder, which is heated to about 95° C., preferably by means of steam. A scraper fitted with teeth, engaging with the grooves of the cylinders, removes the material in a form, in which it hardens in about half an hour, and the hopper is given a transverse movement relatively to the grooves in the cylinder, so as to spread the material evenly over its surface.—O. R.

Fertilizers; Apparatus for use in the production of ——. G. Herrmann, Braunschweig, Germany, and W. J. Fraser and Co., Romford, Essex. Eng. Pat. 17,594, July 31, 1913.

A closed, externally-heated, horizontal, cylindrical vessel adapted to rotate about a series of fixed helical blades by means of which the raw material (shoddy, waste leather, etc.), under treatment is first disintegrated and then discharged by rotation in successively opposite directions. The process is conducted under pressure, steam and acid being introduced axially into the receptacle.—W. E. F. P.

Manure; System for producing efficient fermentation of ——. G. Beccari, Florence, Italy. Eng. Pat. 2998, Feb. 5, 1914. Addition to Eng. Pat. 7496, April 2, 1912 (this J., 1912, 787).

Modifications and alterations in the process (*loc. cit.*) are described. The condensing tower is provided with horizontal tubes connected with chambers forming two sides of the tower and filled with water; the latter circulates through the tubes. Cold air may be circulated through the tubes instead of water. The ammoniacal liquid collecting on the surface of the tubes is led to a concentrating apparatus adjacent to the tower. Tubes, or thermo-siphons, are placed in the manure pit and serve to supply a current of hot air for heating surrounding objects (incubators, hot-houses, etc.) since the fermenting manure frequently attains a temperature exceeding 65° C. —W. P. S.

Fertiliser and process of making the same. G. H. Benjamin, New York. U.S. Pat. 1,105,607, Aug. 4, 1914; date of appl., May 23, 1912.

Lignocellulose is subjected to the action of a hydrolysing acid, and the resulting mixture of lignocellulose and calcium sulphate is divided into three parts. One portion is burnt so that an ash is obtained free from organic matter; a second part is carbonised to obtain amorphous carbon, ash and a calcium compound; the third portion is mixed with ammonia, nitrates and phosphates and the three portions are finally mixed together.—B. N.

Manure; Process for producing efficient fermentation of ——. G. Beccari. First Addition, dated Jan. 28, 1914, to Fr. Pat. 442,220, April 5, 1912.

See Eng. Pat. 2998 of 1914; preceding.—T. F. B.

XVII.—SUGARS; STARCHES; GUMS.

Sugar production of Argentina in 1913. Board of Trade J., Sept. 10, 1914. [T R.]

The quantity of sugar-cane crushed in the Argentine in 1913 was 3,131,018 metric tons, as compared with 2,121,560 metric tons in 1912. The quantity of sugar manufactured was 276,140 metric tons in 1913, as compared with 147,249 metric tons in the previous year. The percentage of sugar to the cane crushed has risen from 6·9 in 1912 to 8·8 in 1913; in one factory in Tucuman the yield was 11 per cent., and in a factory in Jujuy it was 9%. This improved yield is attributed to better climatic conditions, better cultivation, and improved methods of manufacture. During the year 38 mills were in operation, whilst four were idle. Of the active mills 27 were in the province of Tucuman.

Reducing sugars; Behaviour of —— in the manufacture of cane sugar. H. Pellet. Intern. Sugar J., 1914, **16**, 359—362.

At every period of its growth, the sugar cane contains reducing sugars; in the mature plant the quantity is least at the base and greatest at the top of the stalk. The juice from the internodes, which is the softest part, contains more reducing sugars than that from the nodes; hence the glucose ratio of the juices from the second and third crushings is higher than that of the juice from the first crushing. The quantity of reducing sugars in the mixed juice is sometimes increased by the decomposition of the cane after cutting, and before passage through the mill, to an extent which is variable with the variety of cane, the temperature, and the time of keeping. The glucose ratio of the initial juice may be with good cane, 1·5—2·0; with ordinary cane, 3—5; with poor cane, 6—8; and with decomposed cane, 12%. Ordinary defecation, with or without sulphitation, does not appreciably modify the amount of reducing sugars; carbonatation, on the other hand, eliminates 15—40%. During the operations previous to evaporation the quantity of reducing sugars either increases or remains constant, and after concentration the syrup does not contain more reducing sugars than the thin-juice from which it originated, provided that the rapidity of the operation is sufficient; it cannot contain less (this J., 1914, 495). In the sugars exported and in all the molasses produced it is impossible to find less reducing sugars per 100 of cane than enters with the juice sent to the evaporators. The glucose ratio of the molasses varies very considerably, depending upon the quality of the cane and on the proportion between the reducing sugars and the non-sugars.—J. P. O.

Sucrose losses; Determination of the —— during evaporation and boiling. C. H. A. Zimmermann. Intern. Sugar J., 1914, **16**, 383.

During manufacture the amount of sulphates in solution always remains constant, and in order to indicate the sucrose lost by inversion it is recommended that the ratio of sucrose to soluble sulphated ash should be employed. The true sucrose content of the mill juice, syrup, and massecuite is determined by double polarisation; while the soluble sulphated ash is determined by ascertaining the total ash by sulphating in the usual manner, and deducting the lime, silica, iron and alumina obtained by precipitation with ammonium oxalate solution containing ammonia, this precipitate being treated with sulphuric acid and incinerated previous to weighing. In an example given the ratios were as follows: mill juice, 33·87; syrup, 33·55; and massecuite, 32·77, which figures denote that there was a total decrease in the ratio of 1·10, corresponding to a loss of 3·24% of the sucrose originally present in the mill juice.—J. P. O.

Double polarization method (of determining sucrose in cane products); Use of zinc dust in the ——. W. E. Cross. Intern. Sugar J., 1914, 16, 357—358.

For the decolorisation of the inverted solution in the double polarisation method of determining sucrose in cane products the use of zinc dust is recommended, the amount added being 0·2—0·5 grm., and the action continued for 2·5—20 minutes. This reducing agent may also be advantageously added previous to the inversion, especially in the analysis of cane molasses, much lighter coloured solutions being thus obtained.—J. P. O.

Bagasse and molasses; Utilisation of ——. N. Deerr. Report of the Committee on Manufacture of Sugar and Utilisation of By-products. Hawaiian Sugar Planters' Association. 1913. Intern. Sugar J., 1914, **16**, 378—382.

In Hawaii there may be a surplus of bagasse amounting to 9·5 per 100 of cane over the amount used for raising steam for the engines, juice-heaters, evaporators, and vacuum pans. It is suggested that this quantity might profitably be utilised as fuel for the distillation of spirit fermented from molasses (from 1 lb. of which it was found that 0·212 lb. of absolute alcohol could be obtained); for the concentration in the distillery of the spent wash to be subsequently employed as manure; for paper manufacture; and for pumping outside the factory, preferably using internal combustion engines.—J. P. O.

Starch and maltose; Action of cold concentrated hydrochloric acid on ——. Velocity of hydrolysis of starch and maltose by cold concentrated and fuming hydrochloric acid. A. J. Daish. Chem. Soc. Trans., 1914, **105**, 2053—2073.

When dextrose is dissolved in fuming hydrochloric acid its specific rotatory power rises within a few minutes to a high value dependent on the concentration of the acid ($[\alpha]_D$= about 115°, 95·5° and 63·61° for 1—2% solutions in acids of sp. gr. 1·210, 1·201 and 1·163 respectively; cp. Willstätter and Zechmeister, this J., 1913, 822) and remains nearly constant for several hours but eventually tends to rise still higher. The first rapid rise is probably due to the transformation of nearly the whole of the dextrose into the α-form, which in pure aqueous solutions has $[\alpha]_D = 110°$. The further slow rise may be accounted for by the formation of a di- or polysaccharide (isomaltose, see Friedrichs, this J., 1914, 328), and this is further indicated by a fall in the cupric-reducing power of the solutions, which becomes appreciable after only 1—2 hours and amounts to about 7% by the time the solutions begin to turn yellow (about 12 hours in the fuming acid). These evidences of synthesis may be observed in dextrose solutions of only 1—2% concentration, in ordinary concentrated acid (sp. gr. 1·103). Applying these facts to the interpretation of the action of hydrochloric acid on starch, the author concludes that a 1—2% solution of potato starch in fuming acid undergoes complete conversion into dextrose in 5—6 hours at the ordinary temperature. After this time the rotation of the products is practically identical with that of the calculated quantity of dextrose in acid of the same concentration, whilst the value found for the reducing power is about 7% low. The hydrolysis of maltose by fuming acid takes place no more rapidly than that of starch, so that the former process seems to be the determining factor in the rate of conversion of starch into dextrose, the earlier dextrin-stages being rapidly passed through as in hydrolysis by taka-diastase (see Davis and Daish, this J., 1914, 657). There appears to be no difference in the course of hydrolysis, as effected by acids and by enzymes, except in the relative velocity of the different stages (see Fernbach and Schoen, this J., 1912, 402). Ordinary concentrated hydrochloric acid converts starch completely into dextrose, but only about one-tenth as rapidly as the fuming acid. Acid of sp. gr. 1·083 dissolves starch fairly readily in the cold, but conversion into dextrose is extremely slow; cold acid of sp. gr. 1·049 has scarcely any solvent action.

By extrapolation of the velocity curve representing the hydrolysis of maltose by hydrochloric acid, it is calculated that the value of $[\alpha]_D^{20°}$ for maltose in fuming acid of sp. gr. 1·201, before any hydrolysis has occurred, is 157·4°, and in ordinary concentrated acid, 141·0°. Pure aqueous solutions of maltose which have undergone mutarotation probably contain a mixture of β-glucose-α-glucoside (βα-maltose), for which $[\alpha]_D = 114°$, with α-glucose-α-glucoside (αα-maltose), for which $[\alpha]_D$ probably exceeds 160°. In presence of strong hydrochloric acid the proportion of the latter is increased. Davis (this J., 1914, 800) has suggested that the unimolecular nature of the hydrolysis of maltose is masked owing to the simultaneous occurrence of three transformations, viz.: (1) βα-maltose→αα-maltose; (2) αα-maltose→α-glucose (2 mols.); (3) α-glucose→

equilibrium mixture of α- and β-glucose. In the nearly neutral solutions necessary for enzymic actions, transformations (1) and (3) proceed rather slowly and the unimolecular character of the main reaction (2) is masked. When hydrolysis is effected by fuming hydrochloric acid, however, reaction (1) is almost instantaneous, the specific rotatory power of the maltose rising to 157·4° ; and since the dextrose produced remains chiefly in the α-form (see above), reaction (3) is practically eliminated. Under these conditions the author found that the velocity-constant of hydrolysis varied only from 0·0103 to 0·0106. With ordinary concentrated acid, reaction (1) has more effect, since the equilibrium mixture of βα- and αα-maltose approaches more nearly to that obtaining in pure aqueous solutions, and accordingly the author found variations of 0·00170 to 0·00186 in the velocity-constant. In the case of starch the number of intermediate products of hydrolysis renders the conditions more complex ; working with soluble starch and fuming acid the author found velocity-constants ranging from 0·0052 to 0·0062 and, with ordinary concentrated acid, from 0·00111 to 0·00144.—J. H. L.

New constituents of the turnip and sugar beet plants and their biological detection. Kobert. *See* XIXa.

Patents.

Sugar ; Process of making superior ——. N. B. Bach, Modjoherto, Java. U.S. Pat. 1,104,095, July 21, 1914 ; date of appl., Aug. 4, 1913.

For making white sugar, the cane juice is clarified by liming and sulphiting, the resulting juice being neutral and the quantity of lime less than that required for complete liming. The juice is filtered, concentrated, and the thick juice limed, sulphited and filtered, the total quantity of lime both for thin and thick juices being less than the normal quantity required for liming.—J. F. B.

Sugar ; Device for removing —— *from centrifugal machines.* R. Lougher, Papaikou, Hawaii. U.S. Pat. 1,105,444, July 28, 1914 ; date of appl., May 28, 1913.

A rotary support adjustable vertically and placed between a pair of adjoining centrifugals, is fitted with a horizontal arm on which an adjustable carriage is mounted. A bar adjustable vertically is suspended from the carriage, and bears a rotary, dished disc cutter and a guard or shield behind and close to the concave surface of the cutter. —L. E.

Alfalfa ; Manufacture of syrup and other products from ——. M. C. Rich, Hot Springs, S.D. U.S. Pats. (a) 1,104,135 and (b) 1,104,136, July 21, 1914 ; date of appl., Nov. 28, 1911.

(b) Alfalfa, cut before it becomes fibrous and woody, is partially cured in the field, then subjected to artificial heat to prevent bleaching, and ground. (a) The product is boiled with water, the infusion strained and boiled with glucose and a "saccharine syrup."—J. F. B.

Starch or starch-containing materials ; Manufacture of ——. W. and S. L. Elborne, Peterborough, Northants, and A. V. Board, Liverpool. Eng. Pat. 16,997, July 24, 1913.

Starch, *e.g.*, cassava flour (280 lb.), is mixed with water (15 galls.) and passed through a ¼-inch sieve, spread on trays to a depth of about 2 ins., and placed in a steam-jacketed bakers' oven. The oven is heated to about 215° C. until practically all the starch granules are ruptured, the soluble starch being thus liberated. The temperature is then lowered to say 175° C. and the material partially dried for about an hour in a current of air, being raked at intervals of 10—15 mins. ; drying may be completed by prolonging this treatment or by transferring the material to a steam-heated floor on which it is turned over periodically. The pure soluble starch thus obtained is suitable for use in fermentation industries and for food products.—L. E.

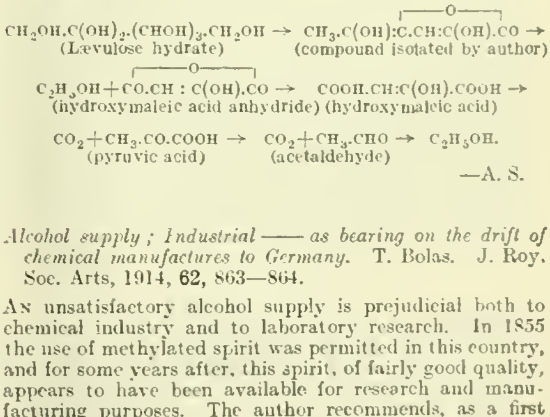
Betaine from molasses or other residues of beet sugar manufacture ; Process for extracting ——. Act.-Ges. f. Anilinfabr. Fr. Pat. 468,366, Feb. 12, 1914. Under Int. Conv., May 7 and Oct. 16, 1913.

See Eng. Pats. 2813 and 2923 of 1914 ; this J., 1914, 658, 767.—T. F. B.

XVIII.—FERMENTATION INDUSTRIES.

Fermentation of some sugars by means of Aspergillus glaucus, and some notes on alcoholic fermentation. F. Tractta-Mosca. Annali Chim. Appl., 1914, 1, 477—492.

Aspergillus glaucus was isolated from soil which had been treated with stable manure by cultivation on nutrient solutions containing sucrose, dextrose, or lævulose. It slowly fermented solutions of these sugars with production of alcohol and carbon dioxide. After prolonged action the solutions of dextrose and lævulose became optically inactive ; the rotatory power of the sucrose solution diminished, then changed its sign, and the lævo-rotation first increased and then remained approximately constant. From the solutions, after fermentation, the author isolated a white crystalline substance of m. pt. 154° C. by extraction with ethyl acetate. This had the composition, $C_6H_6O_4$, and its properties indicated that it was a γ-lactone of the formula, $CH_3.C(OH):\overbrace{C\,CH:C(OH).CO}^{O}$. It was fermented by beer yeast with formation of alcohol and carbon dioxide and is regarded as an intermediate product of alcoholic fermentation, for which the following scheme is suggested :—



$$CH_2OH.C(OH)_2.(CHOH)_3.CH_2OH \rightarrow CH_3.C(OH):\overbrace{C.CH:C(OH).CO}^{O} \rightarrow$$

(Lævulose hydrate) (compound isolated by author)

$$C_2H_5OH + \overbrace{CO.CH:C(OH).CO}^{O} \rightarrow COOH.CH:C(OH).COOH \rightarrow$$

(hydroxymaleic acid anhydride) (hydroxymaleic acid)

$$CO_2 + CH_3.CO.COOH \rightarrow CO_2 + CH_3.CHO \rightarrow C_2H_5OH.$$

(pyruvic acid) (acetaldehyde)

—A. S.

Alcohol supply ; Industrial —— *as bearing on the drift of chemical manufactures to Germany.* T. Bolas. J. Roy. Soc. Arts, 1914, 62, 863—864.

An unsatisfactory alcohol supply is prejudicial both to chemical industry and to laboratory research. In 1855 the use of methylated spirit was permitted in this country, and for some years after, this spirit, of fairly good quality, appears to have been available for research and manufacturing purposes. The author recommends, as a first practical step, that the sale of methylated absolute alcohol in small quantities should at once be authorised by an Order in Council ; abuse could be prevented by licensing only one vendor in each large town and requiring the purchaser to give a written order or otherwise disclose his identity.—L. E.

[Note by Publication Committee.—Ordinary methylated spirit contains 0·4% of a light petroleum spirit and 10% of wood spirit. Industrial methylated spirit contains 5% of wood spirit and no petroleum spirit. Authority to receive and use such spirit is readily obtainable on application to the Commissioners of Customs and Excise and permission to use pure spirit specially denatured to suit particular industries is also granted when the ordinary or industrial methylated spirit is unsuitable.]

Methyl alcohol in spirituous liquors ; Detection of ——. R. Vivario. J. Pharm. Chim., 1914, 10, 145—147.

The alcoholic liquid is treated with anhydrous sodium carbonate and distilled. 30 grms. of the distillate (alcoholic strength of 80%) are then boiled in a reflux apparatus for 7 hrs. with 15 grms. of potassium hydroxide and 1 grm. of hydroxylamine hydrochloride. The liquid is freely diluted with water, made distinctly acid with sulphuric acid and distilled in a current of steam. When methyl alcohol or substances which yield it on boiling with alkali are present, hydrocyanic acid is found in the distillate. Furfural should be first removed by treatment with *m*-phenylenediamine hydrochloride or aniline phosphate. 5% of methyl alcohol in ethyl alcohol can be readily detected.—F. Shdn.

Action of cold concentrated hydrochloric acid on starch and maltose. Velocity of hydrolysis of starch and maltose by cold concentrated and fuming hydrochloric acid. Daish. *See* XVII.

Patents.

Malting drums ; Apparatus for producing and controlling moistened air in ——. L. Topf, Erfurt, Germany. U.S. Pat. 1,104,717, July 21, 1914 ; date of appl., Jan. 12, 1912.

Air is fed through the upper end of a pipe terminating near the bottom of a vertical air chamber ; water is sprayed from nozzles in the pipe to moisten and cool the descending air. The upper portion of the air chamber communicates with a horizontal chamber containing a spiral baffle and having a portion of its walls perforated, this perforated portion being surrounded by a casing. The surplus moisture passes through the perforations and then from the casing, through a pipe, back to the vertical chamber, while the moistened air passes into the drum.—J. F. B.

Metal vessels, beer casks, etc. ; Process and apparatus for treating the interior of ——. Wicküler-Kupper Brauerei Act.-Ges., Elberfeld, Germany. Eng. Pat. 591, Jan. 8, 1914. Under Int. Conv., Feb. 19, 1913.

Lacquer is applied over the internal coating of tin in the barrel and dried by exposing the cask for several weeks. The burning-in of the dried lacquer is effected by blowing hot compressed air through the bung-hole while the latter is inverted, the cask being closely surrounded by a casing in order to retain the heat outside it. The temperature of the compressed air must be sufficient to melt the layer of tin inside the barrel and cause it to combine with the lacquer, say 250° C., and a thermometer placed between the casing and the exterior of the cask should indicate about 120° C. Gases and loose particles of lacquer are driven out by the air through the inverted bung-hole.
—J. F. B.

Fermentation ; Process of alcoholic ——. R. de Fazi, Rome. Eng. Pat. 1335, Jan. 17, 1914.

The saccharine liquid is fermented with yeast previously acclimatised to ultra-violet rays, and is continuously exposed to ultra-violet rays during fermentation. A quantity of cellulose (*e.g.*, small pieces of filter paper), equal to 0·5—2% of the sugar, is added to the liquid, and, being carried up by the carbon dioxide, forms a protecting cover on the liquid.—L. E.

Ferment ; Process of making a ——. P. Altenfeld, New York. U.S. Pat. 1,105,601, Aug. 4, 1914 ; date of appl., Feb. 11, 1913.

Malt is mixed with gelatinised rye flour, and corn-(maize-) flakes and sufficient water are added to make a dough which is allowed to ferment at a low temperature for from 12 to 18 hours.—W. P. S.

Distillation. A. Woolner, jun., Peoria, Ill. U.S. Pat. 1,104,948, July 28, 1914 ; date of appl., Nov. 3, 1910.

Fermented mash is heated for a long time, with stirring, to develop the flavour, and then distilled. The slop is concentrated, the vapour therefrom, which is practically free from substances liable to injure the flavour of the mash, serving to effect the distillation. The vapour produced in distillation may be utilised to preheat the mash.—L. E.

Malt extract ; Process for removing the bitter taste from ——. E. Cantor. Fr. Pat. 468,937, Feb. 25, 1914. Under Int. Conv., March 6, 1913.

See Eng. Pat. 5025 of 1914 ; this J., 1914, 659.—T. F. B.

Distillery wash ; Method of treating ——. G. Meunier, Raab, Assignor to A. and E. Lederer, Vienna. U.S. Pat. 1,107,175, Aug. 11, 1914. Date of appl., May 17, 1911.

See Fr. Pat. 417,950 of 1910 ; this J., 1911, 44.—T. F. B.

Manufacture of starch or starch-containing materials. Eng. Pat. 16,997. *See* XVII.

Manufacture of food preparations or extracts [from yeast and blood]. Eng. Pat. 541. *See* XIXa.

XIXa.—FOODS.

Wheat ; Proximate analysis of ——. N. A. Barbieri. Comptes rend., 1914, **159**, 431—434.

Twenty kilos. of wheat (*Triticum turgidum*) were subjected to the successive action of various neutral solvents. The whole grains were washed with distilled water, macerated for 15 hours with chloroform water, then digested with water at 50°—60° C. until the grains were soft but not broken, and finally boiled with water for an hour and sifted to separate the husks and embryos from the meal. The solid fractions were treated with alcohol and the various washings and extracts worked up. From the aqueous liquids 2 grms. of a yellow colouring matter, "*b'éine*," were obtained by extraction with chloroform. This is regarded as a transformation product of chlorophyll. It is insoluble in water, but soluble in benzene, carbon bisulphide and petroleum ether ; it does not give the biuret or the acrolein reaction. By dialysis of the aqueous extracts potassium sulphate and monopotassium phosphate were obtained, but no chlorides nor any monocalcium phosphate. Extraction of the husks, embryos and meal with ether, yielded 225 grms. of oil, of which 211 grms. were insoluble in alcohol and acetone and free from phosphorus, sulphur and nitrogen, whilst 8 grms. (containing 0·221 grm. P) were soluble in alcohol and acetone and contained traces of "*b'éine*," palmitin, oleopalmitin and phosphates. The ash produced by incineration of the husks, embryos and meal consisted mainly of calcium sulphate and tricalcium phosphate, and was free from carbonates. From the fact that the whole of the phosphorus of an ether extract of wheat is in a form soluble in acetone, whereas lecithin is insoluble, it is concluded that the latter substance is not present in wheat.—J. H. L.

Wheat bran ; The organic phosphoric acid compound of ——. R. J. Anderson. J. Biol. Chem., 1914, **18**, 441—446. (See also this J., 1914, 371.)

The organic phosphorus compound present in wheat bran may be separated into two portions by treatment with barium hydroxide. The soluble portion yields a precipitate with lead acetate, and by repeated precipitation with this reagent, combined with intervening separation of the lead as sulphide from the compound, a solution is obtained which may be concentrated under reduced pressure to a thick colourless syrup. This immediately crystallises to a white solid mass when scratched with a glass rod. The substance may be re-crystallised from dilute alcohol, when large colourless crystals of inositol-monophosphoric acid, $C_6H_{13}PO_9$, are obtained. All the salts of this acid, with the exception of the lead salt, are soluble in cold water. The alkaline-earth salts are not precipitated by ammonia, the acid differing in this respect from other known organic phosphoric acids as well as from ordinary phosphoric acid. Inositol-monophosphoric acid has no sharp m. pt. ; when heated slowly it softens at 200° and decomposes at 201°—202° C. Heated rapidly, it softens at 188° and decomposes at 190° C.—W. P. S.

Phosphorus; Biochemical significance of ——. H. Kincaid. Brit. Assoc., Australia, 1914. Pharm. J., 1914, **93,** 350.

Australian soils are deficient in phosphorus, and native grasses, the wood of trees, and wheat have a lower phosphorus content than those grown in Europe. Acclimatised European grasses contain more phosphorus than do the native grasses but less than the same kind of grasses grown in Europe.—W. P. S.

Milk; The deposit obtained by centrifuging ——. H. S. H. Wardlaw. Brit. Assoc., Australia, 1914. Pharm. J., 1914, **93,** 350.

The white deposit obtained when milk is centrifuged varies somewhat in composition but consists approximately of mineral matters (chiefly calcium phosphate), 8; lactose, 19; caseinogen, 57; other proteins, etc., 16%. The first portion of the substance deposited consists of cellular material, the remainder of minute globules less than 0·001 mm. diameter. About 60% of the deposit is soluble in a volume of water equal to that of the milk from which it was obtained. The mineral content of the deposit at first increases and then decreases as the centrifuging is continued.—W. P. S.

Fats; Changes in the character of ——*, during the process of cooking.* H. Masters and H. L. Smith. Analyst, 1914, **39,** 347—350.

Butter-fat and cottonseed oil, when cooked with flour under normal conditions for making pastry, suffered slight changes similar in character to those which occur in the "blowing" of oils. Except when the pastry was very thin, or over-cooked, the ordinary analytical constants of the fat were not appreciably affected.—W. E. F. P.

Ossein; The nutritive value of —— *and its use as a food.* E. Maurin. Comptes rend., 1914, **159,** 450—452.

Ossein, the protein substance obtained from bones after the removal of mineral matters by treatment with hydrochloric acid, contains from 16 to 18% of nitrogen and about 4% of calcium phosphate and carbonate. It may be prepared in the form of a stable powder and forms a valuable food material.—W. P. S.

Bengal beans, a new fodder. H. S. Shrewsbury. Bull. Dept. Agric., Trinidad and Tobago, 1914, **13,** 194—195.

A sample of Bengal beans, *Stizolobium aterrimum*, contained: water, 12·0; fat, 3·5; proteins, 29·8; crude fibre, 6·2; carbohydrates, 44·3; ash, 4·2%. The beans from a closely related plant, *S. niveum*, possess toxic properties and cause vomiting and purging, but no evidence was found of injurious glucosides, saponins, alkaloids, vegetable ptomaines or toxalbumins in the Bengal beans. Feeding experiments with the beans did not produce any abnormal symptoms in animals.—W. P. S.

Turnip and sugar-beet plants, etc.; New constituents of the —— *and their biological detection.* E. R. Kobert. Z. Ver. deut. Zuckerind., 1914, 381—396.

The following method serves for the detection of certain toxic substances sometimes present in cattle fodder, *e.g.*, ricin (a constituent of castor seeds) and saponin:—Fresh venous blood from a rabbit or guinea-pig is stirred with a wooden rod for several minutes to separate the fibrin, and then strained through unsized gauze. The suspension of corpuscles thus obtained (or the pulpy mass which separates when the liquid is left to stand or centrifuged) is diluted 50—100-fold with isotonic (0·9%) salt solution, and 5 c.c. of the diluted suspension are placed in each of a series of 7 test-tubes. Five c.c. of the salt solution are then placed in the first and last tubes of the series, and increasing quantities of a solution (in 0·9% salt solution) of the toxic substance are placed in the intermediate tubes in succession, the contents of these tubes being made up to 10 c.c. with salt solution; each tube is gently shaken and left for half an hour. The contents of the first and last tubes then exhibit a uniform, opaque, red colour, and on filtration, yield an opaque red liquid without any deposit on the filter. The contents of the intermediate tubes may exhibit either agglutination or hæmolysis of the blood corpuscles. If agglutination occurs, the coagulated particles may be separated by filtration, a colourless filtrate being obtained. This agglutination is effected by a number of non-toxic plant substances known as phasins (occurring in beans, peas, lentils, vetch, earth-nuts, thorn apples, etc.) and by two strongly toxic substances, ricin and abrin (the latter occurring in wild liquorice). Hæmolysis is effected by numerous substances, and of those which occur in higher plants, the saponins are the most important. Whilst some saponins are toxic, others are found in various edible plants and must be regarded as valuable from the dietetic standpoint; thus the sugar beet and turnip each contain a neutral and an acid saponin, and the mangold-wurzel and spinach also contain saponins. It is not therefore justifiable to prohibit indiscriminately the use of saponins for imparting head-retaining power to aerated beverages.—L. E.

Patents.

Butter and the like; Apparatus for testing [determining water-content of] —— *by weighing.* P. Altmann, Berlin. Eng. Pat. 16,681, July 21, 1913. Under Int. Conv., July 20, 1912.

A definite weight of the butter is placed in a cup attached to one arm of a small scale; the cup and its contents are then heated until all the water has been removed, and the cup is replaced on the scale; a pointer attached to the other arm of the scale indicates, on a graduated quadrant, the loss of weight, *i.e.*, the percentage of water present. (Reference is directed to Eng. Pats. 4019 of 1877 and 11,452 of 1889.)—W. P. S.

Milk; Preservation of desiccated ——. T. Boberg, N. Testrup, and Techno-Chemical Laboratories Ltd., London. Eng. Pat. 17,077, July 25, 1913.

Milk powder, prepared by spraying partially concentrated milk into air heated to 120° C., is filled into tins, the residual air in the tins being expelled by means of a current of carbon dioxide. The tins are then sealed.—W. P. S.

Meat; Process of preserving ——. R. R. Cobb, Texarkana, Ark. Eng. Pat. 21,112, Sept. 18, 1913. Under Int. Conv., Sept. 20, 1912.

Strips of meat are immersed in a hot solution prepared by heating saturated sodium chloride solution to 200° F. (93° C.) and adding, for every 100 lb. of meat to be treated, 8 lb. of sodium chloride, 4 lb. of sugar, and 4 oz. each of potassium nitrate, ground black pepper, and borax. After the meat has been placed in the solution, the latter is boiled for 10 mins., the strips of meat being then transferred to a receptacle together with a quantity of the hot solution sufficient to cover them.—W. P. S.

Food preparations or extracts; Manufacture of —— *[from yeast and blood].* E. Krause, Steglitz, Germany. Eng. Pat. 541, Jan. 8, 1914. Under Int. Conv., Feb. 12, 1913.

A mixture of yeast, salt, and blood is submitted to peptic digestion, then boiled, filtered, and the filtrate concentrated to a suitable consistence.—W. P. S.

Lactic food products; Composition for producing ——. W. J. Mellersh-Jackson, London. From C. D. A. Hansen, Copenhagen. Eng. Pat. 1159, Jan. 15, 1914.

One part by weight of dried milk is mixed with 1 part of a compound prepared by incorporating 10 grms. of rennet powder and 57 grms. of calcium hypophosphite with 32 lb. of powdered sugar; solutions of flavouring substances and a binding material may be added before the addition of the sugar. A firm curd is produced within a few minutes when 3·5 oz. of this mixture is treated with 1 pint of water at 100° F. (38° C.). The proportion of rennet employed may be varied.—W. P. S.

Soy-milk product and process of making the same. J. Monahan and C. J. Pope, Oshkosh, Wis. U.S. Pat. 1,104,376, July 21, 1914; date of appl., July 28, 1913.

Soya beans are emulsified with the addition of sodium bicarbonate and coconut oil, the emulsion is separated from the solid portion, heated, filtered, the filtrate is mixed with malt extract and evaporated to dryness under reduced pressure.—W. P. S.

Flour; Dry-shortening ——. A. W. Estabrook and H. E. Weaver, Kansas City, Mo., Assignors to The Larabee Flour Mills Co., Hutchinson, Kans. U.S. Pat. 1,105,638, Aug. 4, 1914; date of appl., Aug. 4, 1913.

Flour is mixed with powdered stearic acid and gas-producing materials.—W. P. S.

Seed-grain; Treatment of ——. H. E. Fry, Dorchester, Assignor to C. E. De Wolf, London. U.S. Pat. 1,106,039, Aug. 4, 1914; date of appl., Oct. 10, 1913.

The grain is immersed in a solution containing nitric acid and a current of electricity is passed through the same. —W. P. S.

Manufacture of starch or starch-containing materials. Eng. Pat. 16,997. *See* XVII.

XIXb.—WATER PURIFICATION; SANITATION.

Water supplies; Purification of public ——. C. H. R. Fuller. Applied Science (Toronto), 1914, 9, 61—73.

Sedimentation.—Quiescent subsidence in a reservoir for a suitable time is largely used as a preliminary to subsequent treatment. At Cincinnati it was observed that in a reservoir of 160 million gallons capacity, a subsidence of 10 hrs. removed 48% of the suspended matter, a subsidence of one day 62%, two days 68%, 3 days 72%, and 4 days 76%. In some cases coagulants are added to the water entering the reservoir, in which case the reservoir is worked on the continuous flow system. The most widely used coagulent is aluminium sulphate, the quantity required depending on the amount and character of the suspended matter. In Saskatoon where the suspended matter varied from 130 to 400 parts per million, 0·28—1·52 grains of aluminium sulphate were added per gallon. Another coagulant is a mixture of ferrous sulphate and milk of lime, which gives good results when the alkalinity of the water is low.

Filtration.—The effluent from the sedimentation reservoir is filtered through sand, either by the slow or rapid system. At Toronto, a modern slow sand filtration plant has been erected recently, in which the rate of filtration is 6 million gallons per acre per day. The twelve filters are covered in, and are each 0·8 acre in area. The filtering material consists of a bottom layer of 7 in. of gravel, 1—2 ins. diameter, a second layer 2·5 ins. deep, of ⅜- to 1-inch gravel, and a top layer of 2·5 ins. of sand of ⅜-inch diameter. In mechanical or rapid sand filters, the rate of filtration is over 100 million gallons per acre per day, and the filters may be either open or closed. The water is always treated with a coagulant previously, and the deposit on the surface of the sand is removed by reversing the flow of water, the cleaning process taking a few minutes only. The reduction in the number of bacteria is 99%. The total cost of the rapid filter operation is about 10 dollars per million gallons.

Sterilisation.—The most general reagent used is bleaching powder in quantity sufficient to give 0·25—0·6 part of available chlorine per million. To remove the taste which is usually imparted to the water, either 1·2 lb. of sodium sulphite or 0·5 lb. of sodium thiosulphate is added for each pound of bleaching powder. Care must be taken not to add either of these until at least 10 mins. after the addition of the bleaching powder, to allow time for sterilisation. Another sterilising agent used in Europe is ultra-violet light. For this process the water must always be rendered clear by filtration and may then be passed at a rate of 130,000 gallons per day through the rays from a one h.p.-lamp. The best lamp is called the pistol lamp and is U-shaped, the two limbs being very close together and enveloped by a two-inch quartz tube. A current of 500 volts and 3 ampères is used. The lamp is situated in a channel and the water is passed through in such a way as to keep it under the influence of the light as long as possible. —J. H. J.

Nitrites [in water, etc.]; Fresenius' method for determining small quantities of ——, *and its sensitiveness compared with the m-phenylenediamine reaction.* E. A. Letts and F. W. Rea. Analyst, 1914, 39, 350—352. (See also this J., 1914, 570.)

In using the zinc-iodide-starch method of Fresenius [" Quant. Anal.," vol. ii., 7th ed. (English)], better results were obtained with 4 c.c. of the reagent and 2 c.c. of dilute sulphuric acid (1 : 5 by vol.) per 50 c.c. of water than by following the original instructions; and the blue colour was found to develop more rapidly in bright, than in dull, light. The results of comparative tests indicated that this method is 10—20 times as sensitive as the *m*-phenylenediamine process.—W. E. F. P.

Patents.

Filtering material for purifying and softening water; Process of preparing ——. Deutsche Filter Compagnie Ges. m. b. H. Fr. Pat. 467,687, Jan. 24, 1914. Under Int. Conv., Jan. 29, 1913.

Vitreous rocks are ground, levigated, and the lighter portion, which possesses base-exchanging properties, is extracted with hydrochloric acid, to remove soluble impurities, washed, and impregnated with sodium chloride solution, whereby the bases present are partly replaced by sodium. When it is desired to use the resulting material for the removal of iron and manganese from water, it may also be treated successively with a manganous salt and a permanganate.—W. P. S.

Sewage disposal. N. Testrup, London, T. Rigby and G. W. Andrew, Dumfries, and Wetcarbonising Ltd., London. Eng. Pat. 16,800, July 22, 1913.

Moderately dry sewage sludge is subjected to distillation in the presence of steam of gradually increasing temperature. In the first stage, ammonia is recovered from the sludge; in the second, the steam is superheated to 250°—300° C. in order to remove greases from the sludge; the residual sludge is then heated to about 800° C. to produce gas. The amount of air admitted to the still is regulated and the different zones in the still are separated by water-cooled valves. (See also Eng. Pat. 3247 of 1911; this J., 1912, 601.)—W. P. S.

Sewage or any other liquid; Process of and apparatus for purifying ——. L. Linden, Brussels. Eng. Pat. 1266, Jan. 16, 1914.

The sewage is introduced into a tank through a conical pipe reaching nearly to the bottom. Along the bottom of the tank, which inclines upwards towards the outlet end, are a number of wells or pockets separated by partitions provided with perforations. The second well is divided into two compartments by a partition extending from above the water-level nearly to the bottom. The suspended matters in the sewage settle in the wells and are withdrawn therefrom when necessary. Movable bands of fabric may be fitted over the perforated partitions and, when the sewage has been treated previously with lime, carbon dioxide is introduced into the sediment collecting in the first well so as to form calcium carbonate and thus produce a more compact bed of material through which the fresh sewage has to pass. Means are provided for cleansing and sterilising the bands of fabric.—W. P. S.

Liquids such as waste water; Apparatus for separating solid matter, more particularly fibrous matter, from ——. B. Hofer, Munich, Germany. Eng. Pat. 6793, March 17, 1914. Under Int. Conv., March 17, 1913.

THE effluent, such as that from a paper factory, is conducted through a pipe into a funnel-shaped vessel mounted within a tank having a conical bottom. The tank is illed previously with water. As the liquid rises slowly n the funnel, the fibrous material collects into lumps or layers which pass over the upper edge of the funnel and fall to the bottom of the tank; the clear liquid eaves the upper part of the tank and a screw-conveyor removes the fibrous material collecting at the bottom of the apparatus.—W. P. S.

Refuse destructor and other furnaces; Apparatus for charging ——. H. N. Leask, Liscard, Cheshire. Eng. Pat. 17,449, July 30, 1913.

A PACKING of flexible material, such as asbestos, wire-auze, or lead, is fitted round the door of the container rom which the refuse is discharged into the furnace, n order that dust shall not escape while the container s being filled with refuse.—W. P. S.

Clothing, furs, skins, etc.; Process for protecting —— against moths, beetles and insects, or for killing domestic and agricultural pests. Act.-Ges. für Anilin-Fabrikation. Berlin. Eng. Pat. 10,379, April 27, 1914. Under Int. Conv., Sept. 10, 1913.

BESIDES *p*-dichlorobenzene, specified in Eng. Pat. 19,688 of 1912 (this J., 1912, 1026), the other isomeric dichloro-enzenes may be used, also mono-, tri- and tetrachloro-enzenes or a mixture such as is obtained in the course of he manufacture of chlorobenzenes, also chloro-derivatives of a homologue of benzene.—I. F. B.

Clothes, furs, skins, and other articles; Process for protecting —— from attacks by moths or other insects. Act.-Ges. f. Anilinfabr. First Addition, dated Jan. 30, 1914, to Fr. Pat. 442,719, April 18, 1912. Under Int. Conv., Sept. 10, 1913.

EE Eng. Pat. 10,379 of 1914; preceding.—T. F. B.

XX.—ORGANIC PRODUCTS; MEDICINAL SUBSTANCES; ESSENTIAL OILS.

xportation of cocaine and cinchona bark from the Netherlands. Board of Trade J., Sept. 10, 1914. [T.R.]

HE prohibition of the exportation of cocaine and of nchona bark and products made therefrom under the ecree of August 7 is temporarily repealed.

oca alkaloids. A. W. K. de Jong. Chem. and Drug., 1914, **85**, 280.

n view of serious attempts to manufacture coca alkaloids Java, two methods of extraction are suggested. (1) n excess of alkali is added to the coca leaves themlves or to an extract of the same made with dilute acid, hen the alkaloids can be extracted with chloroform amyl alcohol. (2) The leaves are extracted with a lute acid, as is done in Peru, excess of alkali added the extract, and the alkaloids extracted with loroform or amyl alcohol.—F. Shdn.

copolamine hydrobromide]. $C_{17}H_{21}NO_4,HBr.3H_2O$*: Criticism of the U.S.P. as to the naming of the compound ——, and the prescribed tests for the same.* A. G. Du Mez. Amer. J. Pharm., 1914, **86**, 339—349.

RACTICALLY all the scopolamine hydrobromide or the -called hyoscine hydrobromide used in the United ates is at present supplied by Germany. It is suggested that in the U.S. Pharmacopœia the former should be the official title, that the melting points of the chloroaurates of either *l*- or i-scopolamine should be omitted and that only *l*-scopolamine hydrobromide with a definite specific rotatory power should be recognised.—F. Shdn.

m-Nicotine. E. Maass and K. Zablinski. Ber., 1914, **47**, 1164—1173.

BENZOYL-*m*-NICOTINE crystallised from ether in fine colourless highly refractive needles, m.pt. 82° C. The base readily formed condensation products, such as phenyl-*m*-nicotinylurea, $C_{17}H_{19}N_3O$, which crystallised from alcohol and melted at 108° C., and phenyl-*m*-nicotinylthiourea, $C_{17}H_{19}N_3S$, m.pt. 137° C. after crystallisation from alcohol. Mononitroso-*m*-nicotine, $C_{10}H_{13}N_3O$, formed colourless silky needles, m.pt. 116° C. When the base was heated to 250°—260° C. with red phosphorus and hydriodic acid, dihydro-*m*-nicotine, $C_{10}H_{16}N_2$, and β-butylpyridine were produced and were separated by fractional distillation. The former boiled at 260°—262° C. and formed a stable colourless oil, fairly easily soluble in water. It yielded a platinum double salt melting at 197° C., and when reduced by means of alcohol and sodium yielded octohydro-*m*-nicotine, $C_{10}H_{22}N_2$, b.pt. 257°—260° C. β-Butylpyridine, $C_9H_{13}N$, a colourless oil insoluble in water, boiled at 205°—208° C. The hydrochloride melted at 126° C. and the platinum double salt at 187°—188° C. β-Butylpiperidine, $C_9H_{19}N$, was formed by reduction with sodium and alcohol. It was a colourless oil boiling at 196°—197° C. and gave a hydrochloride, m.pt. 102° C., and a picrate, m.pt. 124° C. —F. Shdn.

β-Gnoscopine; Synthesis of ——. Synthetical experiments in the group of the isoquinoline alkaloids. Part IV. E. Hope and R. Robinson. Chem. Soc. Trans., 1914, **105**, 2085—2104.

NITROMECONINE and cotarnine condense readily in boiling alcoholic solution to form nitro-β-gnoscopine, $C_{22}H_{22}O_9N_2$, which crystallises from trichloroethylene in canary-yellow prisms, m.pt. 191° C. It forms a hydrochloride, m.pt. 142°—143° C., which yields nitromeconine and cotarninium chloride when the aqueous solution is boiled. β-Gnoscopine, $C_{22}H_{23}O_7N$, can be obtained by eliminating the NO_2 group by successive conversion into $\cdot NH_2$, $\cdot NH\cdot NH_2$, $\cdot H$ or into $\cdot NH_2$, $\cdot I$, $\cdot H$. It is an optically inactive base, crystallising from methyl alcohol in colourless rectangular prisms, m.pt. 180° C., and isomeric but not identical with gnoscopine. It behaves as a lactone and can be readily converted into nornarceine and narceine. On oxidation, cotarnine and opianic acid are produced. The conclusion is drawn that the substance is a stereoisomeride of narcotine and gnoscopine. It is suggested that the name α-gnoscopine be reserved for the compound previously known as gnoscopine or *r*-narcotine, m.pt. 229° C. β-Gnoscopine is partially converted into α-gnoscopine by prolonged heating of the aqueous alcoholic solution to 100° C.—F. Shdn.

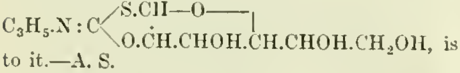
Papaveraldine methosulphate; Oxidation of ——. F. A. Mason and W. H. Perkin, jun. Chem. Soc. Trans., 1914, **105**, 2013—2024.

EQUAL weights of papaveraldine and methyl sulphate were intimately mixed, heated on the water-bath, and the resulting methosulphate crystallised from methyl alcohol. It had the composition, $C_{20}H_{18}O_5N.(CH_3)_2SO_4.CH_3OH$, and formed lemon yellow minute crystals readily soluble in water. Potassium hydroxide added to the aqueous solution produced an orange precipitate soluble in excess of the alkali. When the latter solution was boiled veratric acid and a derivative of 6.7-dimethoxy-N-methyl*iso*quinoline were produced. A solution of the methosulphate in dilute potassium hydroxide solution was readily oxidised by permanganate, the temperature being kept below 30° C.: after filtering veratric acid was precipitated from the solution by adding excess of hydrochloric acid, and three other substances were also isolated, viz., 3.4-dimethoxy-6-methylcarbamylphenylglyoxylic acid,

$C_{12}H_{13}O_6N$, m. pt. 107° C. after crystallising from water, *m*-hemipinmethylimide, $C_{11}H_{11}O_4N$, small needles, m. pt. 266°—267° C., also formed by the oxidation of tho preceding acid, and 6.7-dimethoxy-2-methyl*iso*carbostyril, isolated as a hydrochloride, $C_{12}H_{13}O_3N,HCl$, m. pt. 183°—185° C. Dimethoxy*iso*quinoline methosulphate, m. pt. 202°—203° C., when oxidised by permanganate in alkaline solution yielded the above glyoxylic acid, m. pt. 107° C.—F. SHDN.

Sinigrin ; Constitution of ——. *Mustard-oil glucosides.* W. Schneider and F. Wrede. Ber., 1914, **47**, 2225—2229.

BY the action of potassium methoxide on sinigrin in methyl alcohol solution, thioglucose, $C_6H_{11}O_5.SH$, was produced and was isolated in the form of its silver-compound. Thioglucose is also formed by the action of ammonia gas on a solution of sinigrin in methyl alcohol. Its formation shows that in sinigrin the sugar residue is attached directly to the sulphur atom as in Gadamer's formula, $C_3H_5.N:C(O.SO_2.OK)S.C_6H_{11}O_5$. From the product of the action of potassium methoxide on sinigrin there was also isolated another compound as fine colourless needles, m. pt. 192° C. (uncorr.). This compound, termed *merosinigrin*, is dextro-rotatory ($[\alpha]_D^{20°}=149{\cdot}2°$ in water), yields a triacetyl-derivative and is much more stable than sinigrin, and the formula :—



$$C_3H_5.N:C\begin{cases}S.\dot{C}H—O——\\O.\dot{C}H.CHOH.CH.CHOH.CH_2OH\end{cases}$$

is assigned to it.—A. S.

Ethyl galactoside-β ; Best conditions for the preparation of ——. E. Bourquelot and G. Mougne. J. Pharm. Chim., 1914, **10**, 157—163.

A MIXTURE of 100 grms. of galactose, 16 grms. of emulsin and 2 litres of 80% alcohol is kept at 38°—40° C. for about a month, when the optical rotation changes from +1° 16′ to +48′. The mixture is filtered, evaporated to dryness under reduced pressure and the residue dissolved in 1200 c.c. of distilled water. The solution is allowed to ferment at the ordinary temperature for 10 days after the addition of 15 grms. of dextrose and 30 grms. of washed and pressed bottom-fermentation yeast. The optical rotation changes from +5° 30′ to —30′. The whole is filtered, boiled with a little chalk and charcoal, again filtered and evaporated under reduced pressure. The residue is extracted with hot absolute alcohol and the ethyl galactoside-β purified by recrystallising from the same solvent, using animal charcoal. It forms fine colourless needles, m. pt. 161°—162° C. and with $[\alpha]_D = —7{\cdot}21°$.—F. SHDN.

Anemonin. Y. Asahina. Ber., 1914, **47**, 914—916.

THE fresh roots of the Japanese weed, *Ranunculus japonicus*, were distilled in a current of steam and the distillate extracted with ether, when about 0·12% of an oil was obtained. On standing the oil deposited crystals of anemonin, $C_{10}H_8O_4$, which were crystallised from alcohol and melted at 157°—158° C. Upon further heating the substance solidified at 180° C. and decomposed towards 300° C. Reduction by means of hydrogen in the presence of platinum black led to the formation of tetrahydroanemonin. After crystallising from hot water this formed tablet-shaped crystals which melted at 155° C. and remained liquid up to about 300° C., when decomposition took place.—F. SHDN.

Andrographis paniculata ; Constituents of ——. K. Bhaduri. Amer. J. Pharm., 1914, **86**, 349—354.

THE bitter *Andrographis paniculata* (Nees) is a common Indian plant. Extraction with light petroleum withdrew an essential oil and a small quantity of a crystalline substance, m. pt. 117° C. Chloroform removed chlorophyll and a minute amount of an amorphous white substance, m. pt. 221° C. The alcoholic extract was distilled with steam, when the aqueous portion of the residue deposited yellow crystals of a bitter substance. This had the composition, $C_{19}H_{28}O_5$, melted at 206°, and yielded an acetyl compound, m. pt. 95° C., and a dibromo-derivative. The hot aqueous extract of the solid residue left after steam distillation deposited a white amorphous substance with a very bitter taste, which is styled *kalmeghin*, $C_{19}H_{51}O_5$. It melted at 185° C. and after treatment with acid yielded *kalmeghic acid*, $C_{14}H_{23}O_2$.—F. SHDN.

Fenugreek seeds. Wunschendorff. J. Pharm. Chim., 1914, **10**, 152—157.

FRESH seeds taken from growing fenugreek plants have a sweetish taste and no disagreeable odour. On drying the odour and bitter taste rapidly develop, only to disappear again when the seeds are allowed to germinate. Seeds which have been boiled with alcohol remain inodorous and insipid on keeping, owing to the destruction of the diastatic agents.—F. SHDN.

Oil of Ocymum pilosum, Roxb. K. Bhaduri. J. Amer Chem. Soc., 1914, **36**, 1772—1773.

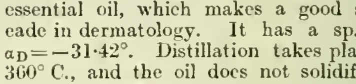
ALL parts of the plant contain oil, the green seeds bein richer than the leaves ; the dried seeds yield no oil o distillation. A jelly produced by soaking the seeds i water is used medicinally by the natives in India. small quantity of the oil was obtained in the laborator by steam distillation. It is a mobile yellow liquid havin an odour closely resembling that of lemongrass oil sp. gr. 0·8872 at 25·5° C., refractive index 1·4843 a 24·5° C., optical rotation at 24·5° C., —3·7° in a 100 mm tube. It distils mainly at 205°—230° C., and contain citral, citronellal, cineol, limonene, and a very sma quantity of thymol, but no methylchavicol. The per centage of aldehydes, as determined by shaking with solution of sodium sulphite and bicarbonate, was 75% by vol., of which 41% was citral and 34% citronellal.—A. S.

Cadier [Juniperus oxycedrus] ; Essential oil from t wood of ——. Huerre. J. Pharm. Chim., 1914, 1 164—165.

THE wood of *Juniperus oxycedrus* yields 3·0 to 1·6% essential oil, which makes a good substitute for oil cade in dermatology. It has a sp. gr. of 0·925, a $\alpha_D = —31{\cdot}42°$. Distillation takes place between 330° a 360° C., and the oil does not solidify at —15° C. It slightly soluble in water, dissolves readily in most orga solvents, and will take up considerable quantities menthol, salol, iodoform, sulphur, etc.—F. SHDN.

Phosphates of 2.3-distearin. R. R. Renshaw and R. Stevens. J. Amer. Chem. Soc., 1914, **36**, 1770—1772.

THE work of Grün and Kade (Ber., 1912, **45**, 3358) the preparation of the primary *o*-phosphate of 2.3-distea by the action of phosphoric anhydride on distearin confirmed. In attempting to simplify the process preparation the sodium salt of a pyrophosphate, probal



$$\begin{matrix}C_{17}H_{35}.CO.O.CH_2.CH.O.PO(ONa)\\ \qquad\qquad\qquad\quad | \\ \qquad\qquad\qquad\quad CH_2.O.PO(ONa)\end{matrix}\Big>O,$$

was obtained. A mixture of 2·5 grms. of distearin a 1·3 grms. of phosphorus pentoxide was heated for 1 h at 100° C., with constant stirring, the product was pow ered, and introduced, with stirring, into a satura solution of sodium bicarbonate. The brownish precipit was filtered off, washed with water, and freed from ste and distearin by extraction with acetone. One-fourth the residue was soluble in boiling benzene : the insolu portion was boiled with water (with liberation of ste acid) and its concentrated aqueous solution precipita with acetone. The combined soluble products w purified by dissolving in benzene, precipitating v acetone, and recrystallising from petroleum ether. pure sodium salt formed prismatic plates, m. pt. 16 168° C. (uncorr.). The silver, barium, and calcium s were also prepared. The authors found that the phosph of distearin tend to hydrolyse with formation of prod poorer in fatty acid, and not the reverse as stated by G and Kade (*loc. cit.*).—A. S.

'hromoform. K. H. Schmitz. Apoth.-Zeit., 1914, **29**, 465—466.

'HROMOFORM is an orange-red crystalline powder formed y the combination of dichromic acid and hexamethylene-·tramine, and has the composition $(C_6H_{12}N_4CH_2)_2Cr_2O_7$. t is only slightly soluble in alcohol and cold water, but ısily in hot water. Warming the aqueous solution or ·eatment with acids or alkalis causes the liberation of ırmaldehyde.—F. SHDN.

hloral and paraldehyde; Manufacture of ——. Chem. and Drug., 1914, **85**, 336.

CURRENT of chlorine is passed through 120 to 150 lb. of bsolute alcohol in a glass carboy for 12 to 14 days. The ·mperature rises to 60°—70° C. and the product finally equires a density of 41° B. (sp. gr. 1·397). The carboy is ırrounded by cold water which is gently heated as soon ı the chlorine ceases to be absorbed. The crude product heated with an equal weight of sulphuric acid in a aden vessel. When all the hydrochloric acid has passed I, the product is distilled, the chloral passing over etween 95° and 100° C. After redistillation this is mverted into chloral hydrate by adding 12·25% of ater. The product can be crystallised from chloroform. ldehyde is obtained from the first runnings in alcohol il's, the best yields coming from alcohol manufactured om potatoes or sugar-beet. Polymerisation to par-dehyde is effected by the addition of a few drops of ncentrated sulphuric acid, and purifying the crystalline ass that separates.—F. SHDN.

cetanilide; Determination of ——. A. Mirkin. Amer. J. Pharm., 1914, **86**, 354—355.

NE grm. of acetanilide is boiled with dilute sulphuric id (1 : 5) for 4 hrs., and carefully neutralised with sodium carbonate when cold. Hydrochloric acid is then added the proportion of 6 mols. to 1 mol. of aniline and the hole cooled to —10° C. Standard sodium nitrite solution run in, with constant shaking, till a drop of the mixture ken out after a few minutes' stirring turns starch-iodide iper blue.—F. SHDN.

enzoic acid; The catalytic decomposition of ——. P. Sabatier and A. Mailhe. Comptes rend., 1914, **159**, 217—220.

HE vapours of benzoic acid were not appreciably affected 550° C. by passing over cerium, zirconium, or barium xides, or the blue oxide of molybdenum or of tungsten, but ere decomposed readily by copper or cadmium, titanium, zinc oxides, and slowly by thorium or chromium oxides alumina (prepared at low temperature), yielding benzene ıd carbon dioxide. Lithium carbonate, calcium car-bnate, or manganous oxide also gave benzene and carbon oxide, but, in addition, benzophenone and a little ıthraquinone, whilst reduced nickel or nickel oxide fected dehydrogenation, with production of carbon and oundant evolution of carbon dioxide, hydrogen, and ethane. Reduced iron resembled both nickel and copper ı its action, giving carbon, hydrogen, gaseous hydro-ırbons, benzene, and diphenyl, and iron oxides (being duced) behaved like the metal, except that some henol (a trace only, with ferrous oxide) was formed. —F. SODN.

enzoyl peroxide as an agent for displacing sulphur. L. Vanino and A. Schinner. Ber., 1914, **47**, 699—703.

ENZOYL peroxide, which is used under the name of lucidol" as a bleaching agent for oils and fats, will ·move sulphur from sulphurised ketones and similar iocarbonyl compounds. When an alcoholic solution of iourea is treated with benzoyl peroxide practically the hole of the sulphur (up to 97·9%) is separated, but at igher temperatures part of the sulphur is dissolved by ıe alcohol. In the reaction cyanamide is formed as a rimary product and dicyandiamide as a secondary roduct of the decomposition. Diphenylthiourea can be esulphurised in the same way, but attempts to remove ıe sulphur from mustard oil were unsuccessful. In similar experiments with hydrogen peroxide no removal of sulphur from thiourea was effected at the ordinary temperature, but an addition compound, $CS(NH_2)_2,H_2O_2$, was obtained. This crystallised in transparent prisms (m. pt. 128°—130° C.), which were readily soluble in water, but were insoluble in alcohol, ether, acetone, chloroform and carbon bisulphide.—C. A. M.

Aminoguanidine and diaminoguanidine; Preparation of ——. G. Pellizzari and A. Gaiter. Gaz. chim. ital., 1914, **44**, II., 72—77.

BY the following simple method, a nearly theoretical yield of aminoguanidine, $NH:C(NH_2)NH.NH_2$, in the form of its bicarbonate, can be obtained from commercial calcium cyanamide and hydrazine sulphate. 100 grms. of calcium cyanamide of recent manufacture are ground with 250 c.c. of water and then, with agitation, 19 c.c. of sulphuric acid of 65·5° B. (sp. gr. 1·83), diluted with 200 c.c. of water, and 60 grms. of powdered hydrazine sulphate are added. The pasty mass is left for 1 hour with occasional agitation, filtered with the aid of the pump, and the residue washed with 250 c.c. of water. The solution, containing mainly free cyanamide and neutral hydrazine sulphate, is concentrated to 200 c.c. on the water-bath, any free acid present or developed being neutralised with calcium cyanamide. After filtering from small quantities of calcium sulphate, iron oxide, etc., the solution is heated for 7 hours on the water-bath, the volume being kept constant at 200 c.c. When the cyanamide is completely decomposed, as shown by a test with ammoniacal silver nitrate, the solution is cooled, a cold solution of 48 grms. of potassium bicarbonate in 200 c.c. of water is added, and the precipitated aminoguanidine bicarbonate is filtered off and washed. 54 grms. are obtained from 100 grms. of calcium cyanamide of recent manufacture. Other salts may be prepared from the bicarbonate by double decomposition.

Diaminoguanidine, $NH:C(NH.NH_2)_2$, is best obtained by the interaction of cyanogen bromide and hydrazine hydrate, the reaction being carried out under ether. A solution of 42·5 grms. of cyanogen bromide in 100 c.c. of ether is added gradually, with agitation, to 40 grms. of pure hydrazine hydrate below a layer of 100 c.c. of ether, the containing vessel being cooled with water. When the reaction is complete, the mixture is stirred until the smell of cyanogen bromide disappears, the ether is decanted off, and the residual crystalline magma is dissolved in 200 c.c. of hot alcohol, from which most of the diaminoguanidine hydrobromide separates on cooling, a further quantity being obtained by evaporating the mother liquor to dryness, dissolving the residue in a small quantity of hot alcohol, and cooling: about 52 grms. are obtained altogether. The hydrobromide crystallises in two different forms, viz., small opaque crystals, and long transparent needles which change into the other form; it melts at 262°—263° C. with decomposition.—A. S.

Triaminoguanidine. G. Pellizzari and A. Gaiter. Gaz. chim. ital., 1914, **44**, II., 78—85.

SALTS of triaminoguanidine, $NH_2N:C(NH.NH_2)_2$, are readily obtained by the interaction of salts of guanidine, amino- or diamino-guanidine with 3, 2, or 1 mol. of hydrazine hydrate respectively; salts of guanidine or aminoguanidine are preferably used. A concentrated aqueous solution of the reacting substances may be heated for 2—5 hours in an open vessel on the water-bath and the residue crystallised from water, or an alcoholic solution may be heated under a reflux condenser, when the triaminoguanidine salt separates in the solid condition as it is formed. The nitrate, hydrobromide, hydrochloride, and thiocyanate have been prepared.—A. S.

Acrolein; Preparation of ——. E. J. Witzemann. J. Amer. Chem. Soc., 1914, **36**, 1766—1770.

WOHL and Mylo's method (this J., 1912, 794) is used but with a much simpler apparatus. 100 grms. of dehydrated magnesium sulphate in pieces of ¼—½ in. size, and freed from dust and fine particles, are introduced into a 3-litre round-bottom Kavalier flask connected with a short condenser, which delivers through an adapter into the first receiver containing 100—125 grms. of common salt. The exit tube from the receiver is constricted at the lower end and has a hole in the side about 2·5 cm. above; it is connected with a second condenser which delivers into the receiver for the crude acrolein. 200 grms. of glycerol are introduced into the flask containing the magnesium sulphate and the flask is heated, gently at first, by a ring burner. The first receiver, in which most of the water is retained, is immersed in boiling water and that for the acrolein in ice-water. When acrolein begins to pass over into the second receiver, glycerol is slowly dropped into the generating flask as fast as that present is decomposed. With three sets of apparatus in operation simultaneously, 500 grms. of acrolein can be obtained in 5 hours. When a flask breaks during distillation the odour is mostly that of hot sugar tar and does not cause great inconvenience. An average yield of 43% of crude acrolein is obtained. This usually begins to polymerise at once, but if the small quantity of water always present be not removed, the polymerisation does not proceed far. The pure acrolein (b. pt. 52°—54° C.) obtained by redistillation polymerises quite rapidly; it should be dehydrated with calcium chloride and used immediately; calcium chloride which is alkaline in aqueous solution causes very rapid polymerisation. The generating flask can usually be quickly cleaned with warm water; small quantities of non-acid tar can be easily removed with chromic acid mixture.—A.S.

Vleminckx's solution [*Liquor calcis sulphuratae*]; *Preparation and analysis of* ——. J. L. Mayer. Amer. J. Pharm., 1914, **86**, 355—358.

A mixture of 165 grms. of freshly slaked lime and 250 grms. of sublimed sulphur is added slowly to 1750 c.c. of boiling water in a flask. The whole is boiled till the weight is reduced to 1000 grms., strained, allowed to settle in a stoppered bottle, and the clear brown liquid decanted and stored in bottles filled to the stopper. Solutions prepared in this way contained 29·1 to 29·6 grms. of total sulphur in 100 c.c., as determined by adding excess of sodium or potassium hydroxide, warming with hydrogen peroxide, acidifying with hydrochloric acid, and precipitating with barium chloride.—F. Shdn.

Syrup of iron iodide; Value of preservatives in ——. G. M. Beringer. Amer. J. Pharm., 1914, **86**, 358—359.

When syrup of iron iodide is made carefully and with the proper amount of sugar, no preservative is needed. Hypophosphorous acid as a preservative has a reducing action which is not possessed by organic acids such as citric and tartaric acids. It acts on the sugar in strong solutions and causes darkening, which could be obviated by substituting glycerin for a portion of the sugar.—F. Shdn.

Arsenical compounds combined with silver and antimony salts for the treatment of trypanosomatic diseases. J. Danysz. Comptes rend., 1914, **159**, 452—455.

The sulphate of arsenobenzene-silver bromide (product 882; see this J., 1914, 275) combines with a certain quantity of antimony, yielding the sulphate of dihydroxydiaminoarsenobenzene-silver-antimonyl bromide, $[C_{12}H_{12}O_2N_2As_2]_2AgBrSbO(H_2SO_4)_2$. This substance (product 102′) is about twice as efficient as arsenobenzene-silver bromide and is particularly active in the case of *T. gambiense.* Experiments on mice showed that the ratio of the maximum dose tolerated to the curative dose is as 80 : 1. The curative dose appears to be about 0·01 grm. per kilo. of body weight.—W. P. S.

Mercuric acetate and aniline; New compound of ——. L. Vecchiotti. Gaz. chim. ital., 1914, **44**, II., 34—38.

Pesci and others (Gaz. chim. ital., 1892, **22**, II., 608) by the interaction of mercuric acetate and aniline, obtained a compound which was shown later by Pesci (Gaz. chim. ital., 1899, **29**, I., 394) and by Dimroth (Ber., 1902, **35**, 2032; Z. anorg. Chem., **33**, 311) to have the constitution $C_6H_4(NH_2).HgC_2H_3O_2[NH_2 : HgC_2H_3O_2=1 : 4]$. The author has now obtained, by the interaction of 1 mol. of aniline and 2 mols. of mercuric acetate in aqueous solution, a white crystalline compound of the formul $C_6H_3(NH_2)(HgC_2H_3O_2)_2$ [1 : 2 : 4]. It is soluble in glaci acetic acid and in ammonia, with which it combine slightly soluble in boiling water, and insoluble in alcoho On treatment with caustic potash it yields the correspond ing mercuric hydroxide compound, $C_6H_3(NH_2)(HgOH)$, which is slightly soluble in boiling water and insoluble i alcohol. The constitution of the mercuric acetate con pound was proved by converting it into its acetyl-derivativ (compare Pesci, Chem.-Zeit., 1899, **23**, Nr. 7) and decon posing this with bromine, 1.2.4.-dibromoacetanilid m. pt. 146° C., being obtained.—A. S.

Iodine; Biochemistry of ——. *Distribution of iodine plant and animal tissues.* A. T. Cameron. J. Bio Chem., 1914, **18**, 335—380.

An exhaustive examination of numerous vegetable ar animal tissues showed that iodine is an invariable const tuent of all marine algæ, the quantity exceeding 0·001% distinct variation in the iodine-content is found in t same species growing under identical conditions. Diffe ence in iodine-content of the environment explains t difference in the quantities of iodine present in fresh-wat plants and vegetables and in marine algæ. Iodine present in appreciable quantity in certain tissues of marine species; in the higher species there is more differe tiation (and probably less total iodine in the wh organism) until, in the vertebrates, thyroid tissue alo is of consequence. Also in the case of mammalian tiss the thyroid gland alone is of importance in the stora of iodine; non-thyroid tissue contains less than 0·001 of iodine. Variations due to differences in diet observable in the case of the thyroid gland; the minim quantity present is about 0·01% whilst the maxim may reach 1·16%.—W. P. S.

Lanthanum and thorium salts; Bactericidal and antito. action of —— *on the cholera vibrio.* A. Frouin and Roudsky. Comptes rend., 1914, **159**, 410—413.

The sulphates of lanthanum and thorium had no injuri action on the human subject. Small amounts of the sa in solution destroyed the toxicity of cultures of chol bacilli and had a beneficial action in cases of experimen cholera produced in animals.—F. Shdn.

Iodine from marine algæ; Industrial extraction of —
Laurent. *See* VII.

Patents.

Alkali salts of diaminodihydroxyarsenobenzene in combinat with copper and silver; Manufacture of ——. O. Imr London. From Farbwerke vorm. Meister, Lucius, Brüning, Hoechst a/Main, Germany. Eng. Pat. 12 Jan. 16, 1914.

A solution of 3.3′-diamino-4.4′-dihydroxyarsenobenz is mixed with small quantities of silver or copper sa sodium hydroxide is added, and the compound forme separated by precipitation or by evaporating the soluti It is of great value for the treatment of sleeping sickn —W. P. S

Carbon tetrachloride package. W. L. Harrison, Branf Conn. U.S. Pat. 1.106,144, Aug. 4, 1914; date appl., Sept. 18, 1913.

Carbon tetrachloride is contained in a cylindrical ve into which compressed air is also introduced; the te chloride is separated from the air by a "follower," which packing containing glycerin is applied to protect tetrachloride from the action of the air.—T. F. B.

Isoprene; Process of producing ——. R. B. Earle L. P. Kyriakides, Assignors to Hood Rubber Boston. U.S. Pat. 1,106,290, Aug. 4, 1914; dat appl., Nov. 11, 1911.

The vapours of methylisopropylketone are passed ov a dehydrating catalyst, such as aluminium silicate, hea o 400°—600° C., under reduced pressure, and the isoprene ormed is separated from the other products.—T. F. B.

3.4-*Dihydroxyphenyl-α-aminopropionic acid ; Process for preparing* ——. F. Hoffmann-La Roche und Co. Ger. Pat. 275,443, Sept. 7, 1913.

HE seeds or hulls of *Vicia faba* are extracted for a short ime with aqueous sulphurous acid ; the extract contains he β-3.4-dihydroxyphenyl-α-aminopropionic acid, which an be isolated by conversion into its insoluble lead comound and decomposing this with sulphuric acid. The ee acid is sparingly soluble in cold water and more easily hot water ; it melts at 280° C. with decomposition and s rotatory power $[\alpha]_D$ —18·91. When it is heated arbon dioxide is eliminated and the corresponding dihyroxyphenylethylamine is produced.—T. F. B.

sters of 2-alkyl- or 2-arylquinolinecarboxylic acids or their derivatives ; Process for preparing ——. Chem. Fabr. auf Actien, vorm. E. Schering. Ger. Pat. 275,963, Oct. 9, 1912.

SOLUBLE salt of a 2-alkyl- or 2-arylquinolinecarboxylic cid or derivative thereof, whether substituted in the enzene or in the pyridine ring, is esterified by treating ith an alkyl halide in presence of water at a high temperare.—T. F. B.

examethylenetetramine di-iodide ; Process for preparing ——. M. Rix. Ger. Pat. 275,974, June 11, 1913.

N antiseptic compound of hexamethylenetetramine with dine is obtained by the action of an aqueous solution of e base on a solution of iodine in an organic solvent which immiscible with water, *e.g.*, benzene or carbon tetraloride. Antiseptic gauze may be prepared by impregating the fabric with hexamethylenetetramine solution d then immersing it in the iodine solution.—T. F. B.

cid chlorides of the oxyacids ; Process for the production of ——. L. Karczag, Charlottenburg, and E. Kopetschni, Mannheim, Germany. U.S. Pat. 1,106,455, Aug. 11, 1914 ; date of appl., Sept. 5, 1912.

E Fr. Pat. 450,227 of 1912 ; this J., 1913, 507.—T. F. B.

etaldehyde ; Process of preparing ——. E. Baum and M. Mugdan, Assignors to Consortium f. Elektrochem. Industrie G. m. b. H., Nuremberg, Germany. U.S. Pat. 1,107,019, Aug. 11, 1914 ; date of appl., July 25, 1913.

E Fr. Pat. 460,553 of 1913 ; this J., 1914, 42.—T. F. B.

hers of phenol homologues halogenated in the side chain ; Process for producing ——. Dr. Schmitz und Co. Fr. Pat. 468,363, Feb. 12, 1914. Under Int. Conv., April 10, 1913.

E Eng. Pat. 3053 of 1914 ; this J., 1914, 767.—T. F. B.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Patent.

gment prints ; Transferring —— *to new supports.* K. Bleibtreu, Bonn, and Deutsche Photogravur Akt.-Ges., Siegburg, Germany. Eng. Pat. 9486, April 16, 1914. Under Int. Conv., April 16, 1913.

E distortion of pigment prints during transfer to metal other surfaces by the wet process, is avoided, according to the present patent, by bringing the dry pigment paper upon the dry support and subsequently moistening the paper ; the air between the paper and the support must be removed before or immediately after moistening, and the pigment paper must be prevented from changing its position on the support during moistening, *e.g.*, by covering the pigment paper with a layer of damp paper or fabric and placing over this an air-tight cover from which the air is then removed.—T. F. B.

XXII.—EXPLOSIVES ; MATCHES.

Explosives ; Annual Report of the Chief Inspector (Major A. B. Denne) of —— *for the Union of South Africa for the year ending Dec.* 31, 1913. [U.G. 28—1914.] (See also this J., 1913, 1033.)

Accidents.—Six accidents occurred in manufacture, of which the chief were : A fire of empty nitrate bags ; an explosion in a packing house in which cartridging, since stopped, was also being carried on (see Special Report, this J., 1913, 627) ; a fire in a nitration house, due to the inadvertent supply of more glycerin than could be taken by the distributor, which, the stirrer having stopped, fired the supernatant nitroglycerin ; an explosion in a kneading house supposed to be due to the dropping of a box of gelatin, or to a blow on the edge of a kneading pan being charged (see Special Report, this J., 1913, 1171). In addition there were 61 accidents with explosives or other dangerous substances, including "outrages," but excluding mining accidents. *Importations.*—Gelatins, gelignites, dynamites, and tshisa sticks are made in S. Africa ; blasting and whaling powders, safety fuse, detonators and electric detonators, sporting powders and ammunition, and fireworks are imported. Statistics are as follows :—

	Blasting gelatin.	Gelignite.	Dynamite	Blasting powder.	Permitted explosives.	Total.	Detonators (number).
anufactured, cases	484,314	240,097	183,729	—	1,643	909,783	—
mported, cases ..	1,371	1,300	2,638	4,363	1,993	11,665	43,562,900
xported, cases ..	10,863	17,734	948	—	—	29,545	31,525

20,321 cases of 500 coils each of safety fuse were imported.
—O. E. M.

White phosphorus matches. Importation forbidden in Canada. Board of Trade J., Sept. 10, 1914. [T.R.]

UNDER the provisions of the "White Phosphorus Matches Act," the manufacture and importation of such matches are forbidden as from January 1, 1915, and their sale or use prohibited after January 1, 1916.

Patents.

Explosive powder ; Apparatus for forming —— *into spherical grains.* F. I. du Pont, Wilmington, Del. U.S. Pat. 1,106,138, Aug. 4, 1914 ; date of appl., Aug. 13, 1913.

THE explosive is supplied to a moving plate having holes, and is forced into the holes. A wheel revolves above the plate and is provided with fingers which enter the holes and force the plugs outwards into a heated receptacle in which they are dried and simultaneously subjected to a rolling motion to shape them into balls.—G. W. McD.

Explosives ; Manufacture of gelatin ——. A. E. Vergé, Vincennes, France. Eng. Pat. 17,205, July 26, 1913. Under Int. Conv., June 23, 1913.

LIQUID dinitrotoluene is prepared by the nitration of a mixture of *m*-mononitrotoluene (60 parts) and *o*-mononitrotoluene (40 parts). From 20 to 25 parts of this liquid dinitrotoluene is mixed with 60 parts of trinitrotoluene. A gelatinous base is made by the addition of

collodion cotton to the nitrotoluene mixture, and oxidising salts (chlorates, perchlorates and nitrates) are then added. Examples are: nitrotoluene mixture (17 parts), nitroglycerin (40), collodion cotton (5), and ammonium perchlorate (38 parts); nitrotoluene mixture (28 parts), collodion cotton (1·7), ammonium perchlorate (43·9) and sodium nitrate (26·4 parts); nitrotoluene mixture (29 parts), collodion (2) and potassium perchlorate (69 parts).
—G. W. McD.

Explosive compounds; Manufacturing ——. Explosive compound. W. C. Waddell, Assignor to Hoynes Safety Powder Co., Cleveland, Ohio. U.S. Pats. (A) 1,105,864 and (B) 1,105,865, Aug. 4, 1914; date of appl., June 27, 1913.

(A) Spherical explosive pellets are produced "by tumbling substantially dry nuclei of explosive material in the presence of dust-like explosive of the same nature, adding a small proportion of moistening liquid and continuing the tumbling, and successively adding more dust-like explosive followed by moistening fluid until said nuclei by accretion have formed substantially spherical units of the size desired." (B) A blasting explosive composed of "a shot-like aggregate of small, imperforate spherical units, each such unit being of uniform character and density throughout and the several units being substantially uniform in size."—G. W. McD.

Priming charge. W. H. Buell, Assignor to Winchester Repeating Arms Co., New Haven, Conn. U.S. Pat. 1,106,343, Aug. 4, 1914; date of appl., Oct. 21, 1913.

A mixture of lead hydrazoate and a nitrated carbohydrate, *e.g.*, nitrocellulose.—G. W. McD.

XXIII.—ANALYTICAL PROCESSES.

Zirconium; Separation of —— from iron and aluminium with the aid of the ammonium salt of nitrosophenyhydroxylamine ("cupferron"). W. M. Thornton, jun., and E. M. Hayden, jun. Amer. J. Sci., 1914, **38**, 137—141.

The method is similar to that previously described for the separation of titanium from iron, aluminium, and phosphoric acid (see this J., 1914, 615), the quantity of tartaric acid used being equal to 5 times the aggregate weight of the three oxides. "Cupferron" forms a very bulky and flocculent white precipitate with zirconium and the method gives accurate results, but is inadmissible in the presence of phosphoric acid.—O. R.

Nitric acid; Detection of —— with ferrous sulphate. I. Bellucci. Annali Chim. Appl., 1914, **1**, 549—558.

A large number of experiments were made under varied conditions and the best results were obtained by dissolving the substance in the smallest possible quantity of water, mixing the solution with excess of concentrated sulphuric acid, and adding to the hot solution, so as to form an upper layer, a solution of ferrous sulphate saturated in the cold: 1 part of nitric acid in 250,000 parts of sulphuric acid could be thus detected. For traces of nitric acid, *e.g.* when the zone reaction gave doubtful results, it was preferable to mix together the reacting substances. For such cases the concentrated solution of the substance was treated with a reagent prepared by dissolving 2·5 grms. of ferrous sulphate in 6—8 c.c. of water acidulated with sulphuric acid and adding the solution to 1 litre of 90% sulphuric acid. This reagent could be kept unaltered for a long time in a closed bottle, and was capable of detecting 1 part of nitric acid in 500,000 parts of sulphuric acid. It is useful for detecting small quantities of nitrous fumes or nitric oxide in gases.—A. S.

Still for the exact measurement of boiling point during fractional distillation; An advantageous ——. T. W. Richards and F. Barry. J. Amer. Chem. Soc., 1914, **36**, 1787—1791.
